

# Package ‘ChainLadder’

August 23, 2014

**Type** Package

**Title** Statistical methods and models for the calculation of  
outstanding claims reserves in general insurance

**Version** 0.1.8

**Date** 2014-08-22

**Description** The ChainLadder package provides various statistical  
methods and models which are typically used for the estimation of  
outstanding claims reserves in general insurance. The  
package has implementations of the Mack, Munich, Bootstrap,multivariate, and chain-  
ladder factor models (CLFM),as well as the loss development factor curve fitting  
methods of Dave Clark and generalised linear model based reserving models.

**Imports** Matrix, actuar, Hmisc, methods, stats, statmod, reshape2,MASS, lattice, grid, tweedie, utils

**Depends** systemfit

**Suggests** RUnit

**License** GPL (>= 2)

**URL** <http://code.google.com/p/chainladder/>

**BugReports** <http://code.google.com/p/chainladder/issues/list>

**LazyLoad** yes

**LazyData** yes

**Author** Markus Gesmann [aut, cre],Daniel Murphy [aut],Wayne Zhang [aut]

**Maintainer** Markus Gesmann <markus.gesmann@gmail.com>

**NeedsCompilation** no

**Repository** CRAN

**Date/Publication** 2014-08-23 11:13:29

ChainLadder-package     *Methods and models for claims reserving*

---

## Description

The ChainLadder-package grew out of presentations given at the Stochastic Reserving Seminar at the Institute of Actuaries in 2007 and 2008 and followed by talks at CAS meetings in 2008 and 2010. This package has currently implementations for the Mack-, Munich- and Bootstrap-chain-ladder methods. The package offers also some utility functions to convert quickly tables into triangles, triangles into tables, cumulative into incremental and incremental into cumulative triangles.

Since version 0.1.4-0 the package also includes the "LDF Curve Fitting" methods of David Clark's paper in the 2003 CAS *Forum*.

The ChainLadder-package comes with an example spreadsheet which demonstrates how to use the ChainLadder functions in Excel. The spreadsheet is located in the Excel folder of the package. The R command `system.file("Excel", package="ChainLadder")` will tell you the exact path to the directory. To use the spreadsheet you will need to have the RExcel-Addin, see <http://sunsite.univie.ac.at/rcom/> for more details. It also provides an example SWord file, demonstrating how the functions of the package can be integrated into a MS Word file via SWord. Again you find the Word file via the command `system.file("SWord", package="ChainLadder")`

More information is available on the project web site <http://code.google.com/p/chainladder/>

If you are also interested in loss distributions modeling, risk theory (including ruin theory), simulation of compound hierarchical models and credibility theory check out the actuar package by C. Dutang, V. Goulet and M. Pigeon.

Brian Fannin's package MRMR provides tools to analyze non-life loss reserves. It uses a set of S3 and S4 objects to store data, models and predictions.

Another package you might want to look into is lossDev. It implements a Bayesian time series loss development model. Features include skewed-t distribution with time-varying scale parameter, reversible jump MCMC for determining the functional form of the consumption path, and a structural break in this path; by Christopher W. Laws and Frank A. Schmid see also <http://lossdev.r-forge.r-project.org/>

For more financial packages see also CRAN Task View 'Emperical Finance' at <http://cran.r-project.org/web/views/Finance.html>.

---

ata	<i>Calculate Age-to-Age Factors</i>
-----	-------------------------------------

---

**Description**

Calculate the matrix of age-to-age factors (also called "report-to-report" factors, or "link ratios") for an object of class `triangle`.

**Usage**

```
ata(Triangle, NArw.rm = TRUE, colname.sep = "-",
    colname.order=c("ascending", "descending"))
```

**Arguments**

<code>Triangle</code>	a loss "triangle". Must be a matrix.
<code>NArw.rm</code>	logical indicating if rows of age-to-age (ata) factors that are all NA should be removed. "All-NA" rows typically occur for the most recent origin year of a loss triangle.
<code>colname.sep</code>	a character indicating the separator character to place between the column names of <code>Triangle</code> that will be used to label the columns of the resulting matrix of ata factors
<code>colname.order</code>	"ascending" indicates that the less mature age comes first in the column labels of the ata matrix

**Details**

`ata` constructs a matrix of age-to-age (ata) factors resulting from a loss "triangle" or a matrix. Simple averages and volume weighted averages are saved as "smp1" and "vwtd" attributes, respectively.

**Value**

A matrix with "smp1" and "vwtd" attributes.

**Author(s)**

Daniel Murphy

**See Also**

[summary.ata](#), [print.ata](#) and [chainladder](#)

**Examples**

```
ata(GenIns)

# Volume weighted average age-to-age factor of the "RAA" data
y <- attr(ata(RAA), "vwtd")
y
# "To ultimate" factors with a 10% tail
y <- rev(cumprod(rev(c(y, 1.1))))
names(y) <- paste(colnames(RAA), "Ult", sep="-")
y

## Label the development columns in "ratio-type" format
ata(RAA, colname.sep=":", colname.order="desc")
```

---

auto

*Run off triangle of accumulated claim data*

---

**Description**

Run-off triangles of Personal Auto and Commercial Auto insurance.

**Usage**

```
data(auto)
```

**Format**

A list of three matrices, paid Personal Auto, incurred Personal Auto and paid Commercial Auto respectively.

BootChainLadder	<i>Bootstrap-Chain-Ladder Model</i>
-----------------	-------------------------------------

---

## Description

The BootChainLadder procedure provides a predictive distribution of reserves or IBNRs for a cumulative claims development triangle.

## Usage

```
BootChainLadder(Triangle, R = 999, process.distr=c("gamma", "od.pois"))
```

## Arguments

Triangle	cumulative claims triangle. Assume columns are the development period, use transpose otherwise. A (mxn)-matrix $C_{ik}$ which is filled for $k \leq n + 1 - i; i = 1, \dots, m; m \geq n$ . See <a href="#">qpaid</a> for how to use (mxn)-development triangles with $m < n$ , say higher development period frequency (e.g quarterly) than origin period frequency (e.g accident years).
R	the number of bootstrap replicates.
process.distr	character string indicating which process distribution to be assumed. One of "gamma" (default), or "od.pois" (over-dispersed Poisson), can be abbreviated

## Details

The BootChainLadder function uses a two-stage bootstrapping/simulation approach. In the first stage an ordinary chain-ladder methods is applied to the cumulative claims triangle. From this we calculate the scaled Pearson residuals which we bootstrap R times to forecast future incremental claims payments via the standard chain-ladder method. In the second stage we simulate the process error with the bootstrap value as the mean and using the process distribution assumed. The set of reserves obtained in this way forms the predictive distribution, from which summary statistics such as mean, prediction error or quantiles can be derived.

## Value

BootChainLadder gives a list with the following elements back:

call	matched call
Triangle	input triangle
f	chain-ladder factors
simClaims	array of dimension $c(m, n, R)$ with the simulated claims
IBNR.ByOrigin	array of dimension $c(m, 1, R)$ with the modeled IBNRs by origin period
IBNR.Triangles	array of dimension $c(m, n, R)$ with the modeled IBNR development triangles
IBNR.Totals	vector of R samples of the total IBNRs

```
ChainLadder.Residuals
                    adjusted Pearson chain-ladder residuals
process.distr      assumed process distribution
R                  the number of bootstrap replicates
```

**Note**

The implementation of `BootChainLadder` follows closely the discussion of the bootstrap model in section 8 and appendix 3 of the paper by England and Verrall (2002).

A
plot(A, log=TRUE)
```

---

chainladder	<i>Estimate age-to-age factors</i>
-------------	------------------------------------

---

**Description**

Basic chain ladder function to estimate age-to-age factors for a given cumulative run-off triangle. This function is used by Mack- and MunichChainLadder.

**Usage**

```
chainladder(Triangle, weights = 1, delta = 1)
```

**Arguments**

Triangle	cumulative claims triangle. A (mxn)-matrix $C_{ik}$ which is filled for $k \leq n + 1 - i; i = 1, \dots, m; m \geq n$ , see <a href="#">qpaid</a> for how to use (mxn)-development triangles with $m < n$ , say higher development period frequency (e.g quarterly) than origin period frequency (e.g accident years).
weights	weights. Default: 1, which sets the weights for all triangle entries to 1. Otherwise specify weights as a matrix of the same dimension as Triangle with all weight entries in [0; 1]
delta	'weighting' parameters, either 0,1 or 2. Default: 1; delta=1 gives the historical chain ladder age-to-age factors, delta=2 gives the straight average of the observed individual development factors and delta=0 is the result of an ordinary regression of $C_{i,k+1}$ against $C_{i,k}$ with intercept 0, see Barnett & Zehnwirth (2000);. Please note that Mack (1999) used the notation of alphas, with $\alpha = 2 - \text{delta}$ .

**Details**

The key idea is to see the chain ladder algorithm as a weighted linear regression through the origin applied to each development period.

Suppose  $y$  is the vector of cumulative claims at development period  $i+1$ , and  $x$  at development period  $i$ ,  $w$  are weighting factors and  $F$  the individual age-to-age factors  $F=y/x$ , than we get the various age-to-age factors for different deltas (alphas) as:

```
sum(w*x^alpha*F)/sum(w*x^alpha) # Mack (1999) notation
```

```
delta <- 2-alpha
```

```
lm(y~x + 0 ,weights=w/x^delta) # Barnett & Zehnwirth (2000) notation
```

**Value**

chainladder returns a list with the following elements:

Models	linear regression models for each development period
Triangle	input triangle of cumulative claims
weights	weights used
delta	deltas used

 ClarkCapeCod

*Clark Cape Cod method*

---

### Description

Analyze loss triangle using Clark's Cape Cod method.

### Usage

```
ClarkCapeCod(Triangle, Premium, cumulative = TRUE, maxage = Inf,
             adol = TRUE, adol.age = NULL, origin.width = NULL,
             G = "loglogistic")
```

### Arguments

Triangle	A loss triangle in the form of a matrix. The number of columns must be at least four; the number of rows may be as few as 1. The column names of the matrix should be able to be interpreted as the "age" of the losses in that column. The row names of the matrix should uniquely define the year of origin of the losses in that row. Losses may be inception-to-date or incremental.
Premium	The vector of premium to use in the method. If a scalar (vector of length 1) is given, that value will be used for all origin periods. (See "Examples" below.) If the length is greater than 1 but does not equal the number of rows of Triangle the Premium values will be "recycled" with a warning.
cumulative	If TRUE (the default), values in Triangle are inception to date. If FALSE, Triangle holds incremental losses.
maxage	The "ultimate" age to which losses should be projected.
adol	If TRUE (the default), the growth function should be applied to the length of time from the average date of loss ("adol") of losses in the origin year. If FALSE, the growth function should be applied to the length of time since the beginning of the origin year.
adol.age	Only pertinent if adol is TRUE. The age of the average date of losses within an origin period in the same units as the "ages" of the Triangle matrix. If NULL (the default) it will be assumed to be half the width of an origin period (which would be the case if losses can be assumed to occur uniformly over an origin period).
origin.width	Only pertinent if adol is TRUE. The width of an origin period in the same units as the "ages" of the Triangle matrix. If NULL (the default) it will be assumed to be the mean difference in the "ages" of the triangle, with a warning if not all differences are equal.
G	A character scalar identifying the "growth function." The two growth functions defined at this time are "loglogistic" (the default) and "weibull".

## Details

Clark's "Cape Cod" method assumes that the incremental losses across development periods in a loss triangle are independent. He assumes that the expected value of an incremental loss is equal to the *theoretical* expected loss ratio (**ELR**) times the on-level premium for the origin year times the change in the *theoretical* underlying growth function over the development period. Clark models the growth function, also called the percent of ultimate, by either the loglogistic function (a.k.a., "the inverse power curve") or the weibull function. Clark completes his incremental loss model by wrapping the expected values within an overdispersed poisson (ODP) process where the "scale factor"  $\sigma^2$  is assumed to be a known constant for all development periods.

The parameters of Clark's "Cape Cod" method are therefore: ELR, and omega and theta (the parameters of the **loglogistic** and **weibull** growth functions). Finally, Clark uses maximum likelihood to parameterize his model, uses the ODP process to estimate process risk, and uses the Cramer-Rao theorem and the "delta method" to estimate parameter risk.

Clark recommends inspecting the residuals to help assess the reasonableness of the model relative to the actual data (see [plot.clark](#) below).

## Value

A list of class "ClarkLDF" with the components listed below. ("Key" to naming convention: all caps represent parameters; mixed case represent origin-level amounts; all-lower-case represent observation-level (origin, development age) results.)

method	"CapeCod"
growthFunction	name of the growth function
Origin	names of the rows of the triangle
Premium	Premium amount for each origin year
CurrentValue	the most mature value for each row
CurrentAge	the most mature "age" for each row
CurrentAge.used	the most mature age used; differs from "CurrentAge" when <code>adol=TRUE</code>
MAXAGE	same as 'maxage' argument
MAXAGE.USED	the maximum age for development from the average date of loss; differs from MAXAGE when <code>adol=TRUE</code>
FutureValue	the projected loss amounts ("Reserves" in Clark's paper)
ProcessSE	the process standard error of the FutureValue
ParameterSE	the parameter standard error of the FutureValue
StdError	the total standard error (process + parameter) of the FutureValue
Total	a list with amounts that appear on the "Total" row for components "Origin" (= "Total"), "CurrentValue", "FutureValue", "ProcessSE", "ParameterSE", and "StdError"
PAR	the estimated parameters
ELR	the estimated loss ratio parameter
THETAG	the estimated parameters of the growth function

GrowthFunction	value of the growth function as of the CurrentAge.used
GrowthFunctionMAXAGE	value of the growth function as of the MAXAGE.used
FutureGrowthFactor	the ("unreported" or "unpaid") percent of ultimate loss that has yet to be recorded
SIGMA2	the estimate of the $\sigma^2$ parameter
Ldf	the "to-ultimate" loss development factor (sometimes called the "cumulative development factor") as defined in Clark's paper for each origin year
LdfMAXAGE	the "to-ultimate" loss development factor as of the maximum age used in the model
TruncatedLdf	the "truncated" loss development factor for developing the current diagonal to the maximum age used in the model
FutureValueGradient	the gradient of the FutureValue function
origin	the origin year corresponding to each observed value of incremental loss
age	the age of each observed value of incremental loss
fitted	the expected value of each observed value of incremental loss (the "mu's" of Clark's paper)
residuals	the actual minus fitted value for each observed incremental loss
stdresid	the standardized residuals for each observed incremental loss (= residuals/sqrt( $\sigma^2$ *fitted), referred to as "normalized residuals" in Clark's paper; see p. 62)
FI	the "Fisher Information" matrix as defined in Clark's paper (i.e., without the $\sigma^2$ value)
value	the value of the loglikelihood function at the solution point
counts	the number of calls to the loglikelihood function and its gradient function when numerical convergence was achieved

**Author(s)**

[ClarkLDF](#)

**Examples**

```

X <- GenIns
colnames(X) <- 12*as.numeric(colnames(X))
CC.loglogistic <- ClarkCapeCod(X, Premium=10000000+400000*0:9, maxage=240)
CC.loglogistic

# Clark's "CapeCod method" also works with triangles that have
# more development periods than origin periods. The Premium
# is a contrived match to the "made up" 'qincurred' Triangle.
ClarkCapeCod(qincurred, Premium=1250+150*0:11, G="loglogistic")

# Method also works for a "triangle" with only one row:
# 1st row of GenIns; need "drop=FALSE" to avoid becoming a vector.
ClarkCapeCod(GenIns[1, , drop=FALSE], Premium=1000000, maxage=20)

# If one value of Premium is appropriate for all origin years
# (e.g., losses are on-level and adjusted for exposure)
# then only a single value for Premium need be provided.
ClarkCapeCod(GenIns, Premium=1000000, maxage=20)

# Use of the weibull function generates a warning that the parameter risk
# approximation results in some negative variances. This may be of small
# concern since it happens only for older years with near-zero
# estimated reserves, but the warning should not be disregarded
# if it occurs with real data.
Y <- ClarkCapeCod(qincurred, Premium=1250+150*0:11, G="weibull")

# The plot of the standardized residuals by age indicates that the more
# mature observations are more loosely grouped than the less mature, just
# the opposite of the behavior under the loglogistic curve.
# This suggests that the model might be improved by analyzing the Triangle
# in two different "blocks": less mature vs. more mature.
# The QQ-plot shows that the tails of the empirical distribution of
# standardized residuals are "fatter" than a standard normal.
# The fact that the p-value is essentially zero says that there is
# virtually no chance that the standardized residuals could be
# considered draws from a standard normal random variable.
# The overall conclusion is that Clark's ODP-based CapeCod model with
# the weibull growth function does not match up well with the qincurred
# triangle and these premiums.
plot(Y)

---

**Description**

Analyze loss triangle using Clark's LDF (loss development factor) method.

**Usage**

```
ClarkLDF(Triangle, cumulative = TRUE, maxage = Inf,
         adol = TRUE, adol.age = NULL, origin.width = NULL,
         G = "loglogistic")
```

**Arguments**

Triangle	A loss triangle in the form of a matrix. The number of columns must be at least four; the number of rows may be as few as 1. The column names of the matrix should be able to be interpreted as the "age" of the losses in that column. The row names of the matrix should uniquely define the year of origin of the losses in that row. Losses may be inception-to-date or incremental.  The "ages" of the triangle can be "phase shifted" – i.e., the first age need not be as at the end of the origin period. (See the Examples section.) Nor need the "ages" be uniformly spaced. However, when the ages are not uniformly spaced, it would be prudent to specify the <code>origin.width</code> argument.
cumulative	If TRUE (the default), values in <code>Triangle</code> are inception to date. If FALSE, <code>Triangle</code> holds incremental losses.
maxage	The "ultimate" age to which losses should be projected.
adol	If TRUE (the default), the growth function should be applied to the length of time from the average date of loss (" <code>adol</code> ") of losses in the origin year. If FALSE, the growth function should be applied to the length of time since the beginning of the origin year.
adol.age	Only pertinent if <code>adol</code> is TRUE. The age of the average date of losses within an origin period in the same units as the "ages" of the <code>Triangle</code> matrix. If NULL (the default) it will be assumed to be half the width of an origin period (which would be the case if losses can be assumed to occur uniformly over an origin period).
origin.width	Only pertinent if <code>adol</code> is TRUE. The width of an origin period in the same units as the "ages" of the <code>Triangle</code> matrix. If NULL (the default) it will be assumed to be the mean difference in the "ages" of the triangle, with a warning if not all differences are equal.
G	A character scalar identifying the "growth function." The two growth functions defined at this time are "loglogistic" (the default) and "weibull".

**Details**

Clark's "LDF method" assumes that the incremental losses across development periods in a loss triangle are independent. He assumes that the expected value of an incremental loss is equal to the *theoretical* expected ultimate loss (U) (by origin year) times the change in the *theoretical* underlying growth function over the development period. Clark models the growth function, also called the percent of ultimate, by either the loglogistic function (a.k.a., "the inverse power curve") or the weibull function. Clark completes his incremental loss model by wrapping the expected values within an overdispersed poisson (ODP) process where the "scale factor"  $\sigma^2$  is assumed to be a known constant for all development periods.

The parameters of Clark's "LDF method" are therefore: U, and omega and theta (the parameters of the **loglogistic** and **weibull** growth functions). Finally, Clark uses maximum likelihood to parameterize his model, uses the ODP process to estimate process risk, and uses the Cramer-Rao theorem and the "delta method" to estimate parameter risk.

Clark recommends inspecting the residuals to help assess the reasonableness of the model relative to the actual data (see [plot.clark](#) below).

## Value

A list of class "ClarkLDF" with the components listed below. ("Key" to naming convention: all caps represent parameters; mixed case represent origin-level amounts; all-lower-case represent observation-level (origin, development age) results.)

method	"LDF"
growthFunction	name of the growth function
Origin	names of the rows of the triangle
CurrentValue	the most mature value for each row
CurrentAge	the most mature "age" for each row
CurrentAge.used	the most mature age used; differs from "CurrentAge" when <code>adol=TRUE</code>
MAXAGE	same as 'maxage' argument
MAXAGE.USED	the maximum age for development from the average date of loss; differs from MAXAGE when <code>adol=TRUE</code>
FutureValue	the projected loss amounts ("Reserves" in Clark's paper)
ProcessSE	the process standard error of the FutureValue
ParameterSE	the parameter standard error of the FutureValue
StdError	the total standard error (process + parameter) of the FutureValue
Total	a list with amounts that appear on the "Total" row for components "Origin" (= "Total"), "CurrentValue", "FutureValue", "ProcessSE", "ParameterSE", and "StdError"
PAR	the estimated parameters
THETAU	the estimated parameters for the "ultimate loss" by origin year ("U" in Clark's notation)
THETAG	the estimated parameters of the growth function
GrowthFunction	value of the growth function as of the CurrentAge.used
GrowthFunctionMAXAGE	value of the growth function as of the MAXAGE.used
SIGMA2	the estimate of the $\sigma^2$ parameter
Ldf	the "to-ultimate" loss development factor (sometimes called the "cumulative development factor") as defined in Clark's paper for each origin year
LdfMAXAGE	the "to-ultimate" loss development factor as of the maximum age used in the model

TruncatedLdf	the "truncated" loss development factor for developing the current diagonal to the maximum age used in the model
FutureValueGradient	the gradient of the FutureValue function
origin	the origin year corresponding to each observed value of incremental loss
age	the age of each observed value of incremental loss
fitted	the expected value of each observed value of incremental loss (the "mu's" of Clark's paper)
residuals	the actual minus fitted value for each observed incremental loss
stdresid	the standardized residuals for each observed incremental loss (= residuals/sqrt(sigma2*fitted), referred to as "normalized residuals" in Clark's paper; see p. 62)
FI	the "Fisher Information" matrix as defined in Clark's paper (i.e., without the sigma^2 value)
value	the value of the loglikelihood function at the solution point
counts	the number of calls to the loglikelihood function and its gradient function when numerical convergence was achieved

```

---

CLFMdelta

*Find "selection consistent" values of delta*

---

### Description

This function finds the values of delta, one for each development period, such that the model coefficients resulting from the 'chainladder' function with delta = solution are consistent with an input vector of 'selected' development age-to-age factors.

### Usage

```
CLFMdelta(Triangle, selected, tolerance = .0005, ...)
```

### Arguments

Triangle	cumulative claims triangle. A (mxn)-matrix $C_{ik}$ which is filled for $k \leq n + 1 - i; i = 1, \dots, m; m \geq n$ , see <a href="#">qpaid</a> for how to use (mxn)-development triangles with $m < n$ , say higher development period frequency (e.g quarterly) than origin period frequency (e.g accident years).
selected	a vector of selected age-to-age factors or "link ratios", one for each development period of 'Triangle'
tolerance	a 'tolerance' parameters. Default: .0005; for each element of 'selected' a solution 'delta' will be found – if possible – so that the chainladder model indexed by 'delta' results in a multiplicative coefficient within 'tolerance' of the 'selected' factor.
...	not in use

### Details

For a given input Triangle and vector of selected factors, a search is conducted for chainladder models that are "consistent with" the selected factors. By "consistent with" is meant that the coefficients of the [chainladder](#) function are equivalent to the selected factors. Not all vectors of selected factors can be considered consistent with a given Triangle; feasibility is subject to restrictions on the 'selected' factors relative to the input 'Triangle'. See the References.

The default average produced by the chainladder function is the volume weighted average and corresponds to  $\text{delta} = 1$  in the call to that function;  $\text{delta} = 2$  produces the simple average; and  $\text{delta} = 0$  produces the "regression average", i.e., the slope of a regression line fit to the data and running through the origin. By convention, if the selected value corresponds to the volume-weighted average, the simple average, or the regression average, then the value returned will be 1, 2, and 0, respectively.

Other real-number values for delta will produce a different average. The point of this function is to see if there exists a model as determined by delta whose average is consistent with the value in the selected vector. That is not always possible. See the References.

It can be the case that one or more of the above three "standard averages" will be quite close to each other (indistinguishable within tolerance). In that case, the value returned will be, in the following priority order by convention, 1 (volume weighted average), 2 (simple average), or 0 (regression average).

### Value

A vector of real numbers, say  $\text{delta0}$ , such that `coef(chainladder(Triangle, delta = delta0)) = selected` within tolerance. A logical attribute 'foundSolution' indicates if a solution was found for each element of selected.

### Examples

```
x <- RAA[1:9,1]
y <- RAA[1:9,2]
F <- y/x
CLFMdelta(RAA[1:9, 1:2], selected = mean(F)) # value is 2, 'foundSolution' is TRUE
CLFMdelta(RAA[1:9, 1:2], selected = sum(y) / sum(x)) # value is 1, 'foundSolution' is TRUE

selected <- mean(c(mean(F), sum(y) / sum(x))) # an average of averages
CLFMdelta(RAA[1:9, 1:2], selected) # about 1.725
CLFMdelta(RAA[1:9, 1:2], selected = 2) # negative solutions are possible

# Demonstrating an "unreasonable" selected factor.
CLFMdelta(RAA[1:9, 1:2], selected = 1.9) # NA solution, with warning
```

coef.ChainLadder	<i>Extract residuals of a ChainLadder model</i>
------------------	---

---

**Description**

Extract residuals of a [MackChainLadder](#) model by origin-, calendar- and development period.

**Usage**

```
## S3 method for class 'ChainLadder'  
coef(object, ...)
```

**Arguments**

object	output of the <a href="#">chainladder</a> function
...	optional arguments which may become named attributes of the resulting vector

**Value**

The function returns a vector of the single-parameter coefficients – also called age-to-age (ATA) or report-to-report (RTR) factors – of the models produced by running the 'chainladder' function.

Cumulative and incremental triangles  
*Cumulative and incremental triangles*

---

**Description**

Functions to convert between cumulative and incremental triangles

**Usage**

```
incr2cum(Triangle, na.rm=FALSE)
cum2incr(Triangle)
```

**Arguments**

Triangle	triangle. Assume columns are the development period, use transpose otherwise.
na.rm	logical. Should missing values be removed?

**Details**

incr2cum transforms an incremental triangle into a cumulative triangle, cum2incr provides the reverse operation.

**Value**

Both functions return a triangle.

## Convert long format into triangle
## Triangles are usually stored as 'long' tables in data bases
as.triangle(GenInsLong, origin="accyear", dev="devyear", "incurred claims")
```

---

getLatestCumulative *Triangle information for most recent calendar period.*

---

## Description

Return most recent values for all origin periods of a cumulative development triangle.

## Usage

```
getLatestCumulative(Triangle, na.values = NULL)
```

## Arguments

Triangle	a Triangle in matrix format.
na.values	a vector specifying values that should be considered synonymous with NA when searching for the rightmost non-NA.

## Value

A vector of most recent non-'NA' (and synonyms, if appropriate) values of a triangle for all origin periods. The names of the vector equal the origin names of the Triangle. The vector will have additional attributes: "latestcol" equalling the index of the column in Triangle corresponding to the row's rightmost entry; "rowsname" equalling the name of the row dimension of Triangle, if any; "colnames" equalling the corresponding column name of Triangle, if any; "colsname" equalling the name of the column dimension of Triangle, if any.

Y <- matrix(c(1, 2, 3,
              4, 5, 0,
              6, NA, NA), byrow=TRUE, nrow=3)
getLatestCumulative(Y) # c(3, 0, 6)
getLatestCumulative(Y, na.values = 0) # c(3, 5, 6)
```

glmReserve

*GLM-based Reserving Model***Description**

This function implements loss reserving models within the generalized linear model framework. It takes accident year and development lag as mean predictors in estimating the ultimate loss reserves, and provides both analytical and bootstrapping methods to compute the associated prediction errors. The bootstrapping approach also generates the full predictive distribution for loss reserves.

**Usage**

```
glmReserve(triangle, var.power = 1, link.power = 0, cum = TRUE,
           mse.method = c("formula", "bootstrap"), nsim = 1000, ...)
```

**Arguments**

triangle	An object of class <code>triangle</code> .
var.power	The index ( $p$ ) of the power variance function $V(\mu) = \mu^p$ . Default to $p = 1$ , which is the over-dispersed Poisson model. If NULL, it will be assumed to be in (1, 2) and estimated using the <code>cp1m</code> package. See <a href="#">tweedie</a> .
link.power	The index of power link function. The default <code>link.power = 0</code> produces a log link. See <a href="#">tweedie</a> .
cum	A logical value indicating whether the input <code>triangle</code> is on the cumulative or the incremental scale. If TRUE, then <code>triangle</code> is assumed to be on the cumulative scale, and it will be converted to incremental losses internally before a GLM is fitted.
mse.method	A character indicating whether the prediction error should be computed analytically ( <code>mse.method = "formula"</code> ) or via bootstrapping ( <code>mse.method = "bootstrap"</code> ). Partial match is supported.
nsim	Number of simulations to be performed in the bootstrapping, with a default value of 1000.
...	Arguments to be passed onto the function <code>glm</code> or <code>cpglm</code> such as <code>contrasts</code> or <code>control</code> . It is important that <code>offset</code> and <code>weight</code> should not be specified. Otherwise, an error will be reported and the program will quit.

**Details**

This function takes an insurance loss triangle, converts it to incremental losses internally if necessary, transforms it to the long format (see `as.data.frame`) and fits the resulting loss data with a generalized linear model where the mean structure includes both the accident year and the development lag effects. The distributions allowed are the exponential family that admits a power variance function, that is,  $V(\mu) = \mu^p$ . This subclass of distributions is usually called the Tweedie distribution and includes many commonly used distributions as special cases. This function does not allow the user to specify the GLM options through the usual `family` argument, but instead, it uses the

`tweedie` family internally and takes two arguments `var.power` and `link.power` through which the user still has full control of the distribution forms and link functions. The argument `var.power` determines which specific distribution is to be used, and `link.power` determines the form of the link function. When the Tweedie compound Poisson distribution  $1 < p < 2$  is to be used, the user has the option to specify `var.power = NULL`, where the variance power  $p$  will be estimated from the data using the `cp1m` package. The `bcplm` function in the `cp1m` package also has an example for the Bayesian compound Poisson loss reserving model. See details in `tweedie`, `cpglm` and `bcplm`.

Also, the function allows certain measures of exposures to be used in an offset term in the underlying GLM. To do this, the user should not use the usual `offset` argument in `glm`. Instead, one specifies the exposure measure for each accident year through the `exposure` attribute of `triangle`. Make sure that these exposures are in the original scale (no log transformations for example), and they are in the order consistent with the accident years. If the `exposure` attribute is not `NULL`, the `glmReserve` function will use these exposures, link-function-transformed, in the offset term of the GLM. For example, if the link function is `log`, then the log of the exposure is used as the offset, not the original exposure. See the examples below. Moreover, the user **MUST NOT** supply the typical `offset` or `weight` as arguments in the list of additional arguments `...` `offset` should be specified as above, while `weight` is not implemented (due to prediction reasons).

Two methods are available to assess the prediction error of the estimated loss reserves. One is using the analytical formula (`mse.method = "formula"`) derived from the first-order Taylor approximation. The other is using bootstrapping (`mse.method = "bootstrap"`) that reconstructs the triangle `nsim` times by sampling with replacement from the GLM (Pearson) residuals. Each time a new triangle is formed, GLM is fitted and corresponding loss reserves are generated. Based on these predicted mean loss reserves, and the model assumption about the distribution forms, realizations of the predicted values are generated via the `rtweedie` function. Prediction errors as well as other uncertainty measures such as quantiles and predictive intervals can be calculated based on these samples.

## Value

The output is an object of class `"glmReserve"` that has the following components:

<code>call</code>	the matched call.
<code>summary</code>	A data frame containing the predicted loss reserve statistics. Similar to the summary statistics from <code>MackChainLadder</code> .
<code>Triangle</code>	The input triangle.
<code>FullTriangle</code>	The completed triangle, where empty cells in the original triangle are filled with model predictions.
<code>model</code>	The fitted GLM, a class of <code>"glm"</code> or <code>"cpglm"</code> . It is most convenient to work with this component when model fit information is wanted.
<code>sims.par</code>	a matrix of the simulated parameter values in the bootstrapping.
<code>sims.reserve.mean</code>	a matrix of the simulated mean loss reserves (without the process variance) for each year in the bootstrapping.
<code>sims.par</code>	a matrix of the simulated realizations of the loss reserves (with the process variance) for each year in the bootstrapping. This can be used to summarize the predictive uncertainty of the loss reserves.

**Note**

The use of GLM in insurance loss reserving has many compelling aspects, e.g.,

- when over-dispersed Poisson model is used, it reproduces the estimates from Chain Ladder;
- it provides a more coherent modeling framework than the Mack method;
- all the relevant established statistical theory can be directly applied to perform hypothesis testing and diagnostic checking;

However, the user should be cautious of some of the key assumptions that underline the GLM model, in order to determine whether this model is appropriate for the problem considered:

- the GLM model assumes no tail development, and it only projects losses to the latest time point of the observed data. To use a model that enables tail extrapolation, please consider the growth curve model [ClarkLDF](#) or [ClarkCapeCod](#);
- the model assumes that each incremental loss is independent of all the others. This assumption may not be valid in that cells from the same calendar year are usually correlated due to inflation or business operating factors;
- the model tends to be over-parameterized, which may lead to inferior predictive performance.

To solve these potential problems, many variants of the current basic GLM model have been proposed in the actuarial literature. Some of these may be included in the future release.

See also [glm](#), [tweedie](#), [cpglm](#) and [MackChainLadder](#).

**Examples**

```
data(GenIns)
GenIns <- GenIns / 1000

# over-dispersed Poisson: reproduce ChainLadder estimates
(fit1 <- glmReserve(GenIns))
summary(fit1, type = "model") # extract the underlying glm

# Gamma GLM:
(fit2 <- glmReserve(GenIns, var.power = 2))

# compound Poisson GLM (variance function estimated from the data):
#(fit3 <- glmReserve(GenIns, var.power = NULL))
```

```

# Now suppose we have an exposure measure
# we can put it as an offset term in the model
# to do this, use the "exposure" attribute of the 'triangle'
expos <- (7 + 1:10 * 0.4) * 100
GenIns2 <- GenIns
attr(GenIns2, "exposure") <- expos
(fit4 <- glmReserve(GenIns2))

# use bootstrapping to compute prediction error
## Not run:
set.seed(11)
(fit5 <- glmReserve(GenIns, mse.method = "boot"))

# compute the quantiles of the predicted loss reserves
t(apply(fit5$sims.reserve.pred, 2, quantile,
        c(0.025, 0.25, 0.5, 0.75, 0.975)))

## End(Not run)

```

---

Join2Fits

*Join Two Fitted MultiChainLadder Models*

---

## Description

This function is created to facilitate the fitting of the multivariate functions when specifying different models in two different development periods, especially when separate chain ladder is used in later periods.

## Usage

```
Join2Fits(object1, object2)
```

## Arguments

object1	An object of class "MultiChainLadder"
object2	An object of class "MultiChainLadder"

## Details

The inputs must be of class "MultiChainLadder" because this function depends on the model slot to determine what kind of object is to be created and returned. If both objects have "MCL", then an object of class "MCLFit" is created; if one has "GMCL" and one has "MCL", then an object of class "GMCLFit" is created, where the one with "GMCL" is assumed to come from the first development periods; if both have "GMCL", then an object of class "GMCLFit" is created.

MackChainLadder	<i>Mack-Chain-Ladder Model</i>
-----------------	--------------------------------

---

**Description**

The Mack-chain-ladder model forecasts future claims developments based on a historical cumulative claims development triangle and estimates the standard error around those.

**Usage**

```
MackChainLadder(Triangle, weights = 1, alpha=1, est.sigma="log-linear",
tail=FALSE, tail.se=NULL, tail.sigma=NULL, mse.method="Mack")
```

**Arguments**

Triangle	cumulative claims triangle. Assume columns are the development period, use transpose otherwise. A (mxn)-matrix $C_{ik}$ which is filled for $k \leq n + 1 - i; i = 1, \dots, m; m \geq n$ , see <code>qpaid</code> for how to use (mxn)-development triangles with $m < n$ , say higher development period frequency (e.g quarterly) than origin period frequency (e.g accident years).
weights	weights. Default: 1, which sets the weights for all triangle entries to 1. Otherwise specify weights as a matrix of the same dimension as Triangle with all weight entries in [0; 1]
alpha	'weighting' parameter. Default: 1 for all development periods; alpha=1 gives the historical chain ladder age-to-age factors, alpha=0 gives the straight average of the observed individual development factors and alpha=2 is the result of an ordinary regression of $C_{i,k+1}$ against $C_{i,k}$ with intercept 0, see also Mack's 1999 paper and <code>chainladder</code>
est.sigma	defines how to estimate $\sigma_{n-1}$ , the variability of the individual age-to-age factors at development time $n - 1$ . Default is "log-linear" for a log-linear regression, "Mack" for Mack's approximation from his 1999 paper. Alternatively the user can provide a numeric value. If the log-linear model appears to be inappropriate (p-value > 0.05) the 'Mack' method will be used instead and a warning message printed. Similarly, if Triangle is so small that log-linear regression is being attempted on a vector of only one non-NA average link ratio, the 'Mack' method will be used instead and a warning message printed.
tail	can be logical or a numeric value. If tail=FALSE no tail factor will be applied, if tail=TRUE a tail factor will be estimated via a linear extrapolation of $\log(\text{chainladder factors} - 1)$ , if tail is a numeric value than this value will be used instead.
tail.se	defines how the standard error of the tail factor is estimated. Only needed if a tail factor > 1 is provided. Default is NULL. If tail.se is NULL, tail.se is estimated via "log-linear" regression, if tail.se is a numeric value than this value will be used instead.
tail.sigma	defines how to estimate individual tail variability. Only needed if a tail factor > 1 is provided. Default is NULL. If tail.sigma is NULL, tail.sigma is estimated via "log-linear" regression, if tail.sigma is a numeric value than this value will be used instead
mse.method	method used for the recursive estimate of the parameter risk component of the mean square error. Value "Mack" (default) coincides with Mack's formula; "Independence" includes the additional cross-product term as in Murphy and BMW. Refer to References below.

**Details**

Following Mack's 1999 paper let  $C_{ik}$  denote the cumulative loss amounts of origin period (e.g. accident year)  $i = 1, \dots, m$ , with losses known for development period (e.g. development year)  $k \leq n + 1 - i$ . In order to forecast the amounts  $C_{ik}$  for  $k > n + 1 - i$  the Mack chain-ladder-model assumes:

$$\text{CL1: } E[F_{ik} | C_{i1}, C_{i2}, \dots, C_{ik}] = f_k \text{ with } F_{ik} = \frac{C_{i,k+1}}{C_{ik}}$$

$$\text{CL2: } \text{Var}\left(\frac{C_{i,k+1}}{C_{ik}} \mid C_{i1}, C_{i2}, \dots, C_{ik}\right) = \frac{\sigma_k^2}{w_{ik} C_{ik}^\alpha}$$

CL3:  $\{C_{i1}, \dots, C_{in}\}, \{C_{j1}, \dots, C_{jn}\}$ , are independent for origin period  $i \neq j$

with  $w_{ik} \in [0; 1]$ ,  $\alpha \in \{0, 1, 2\}$ . If these assumptions are hold, the Mack-chain-ladder-model gives an unbiased estimator for IBNR (Incurred But Not Reported) claims.

The Mack-chain-ladder model can be regarded as a weighted linear regression through the origin for each development period:  $\text{lm}(y \sim x + 0, \text{weights}=w/x^{(2-\alpha)})$ , where  $y$  is the vector of claims at development period  $k + 1$  and  $x$  is the vector of claims at development period  $k$ .

## Value

MackChainLadder returns a list with the following elements

call	matched call
Triangle	input triangle of cumulative claims
FullTriangle	forecasted full triangle
Models	linear regression models for each development period
f	chain-ladder age-to-age factors
f.se	standard errors of the chain-ladder age-to-age factors f (assumption CL1)
F.se	standard errors of the true chain-ladder age-to-age factors $F_{ik}$ (square root of the variance in assumption CL2)
sigma	sigma parameter in CL2
Mack.ProcessRisk	variability in the projection of future losses not explained by the variability of the link ratio estimators (unexplained variation)
Mack.ParameterRisk	variability in the projection of future losses explained by the variability of the link-ratio estimators alone (explained variation)
Mack.S.E	total variability in the projection of future losses by the chain ladder method; the square root of the mean square error of the chain ladder estimate: $\text{Mack.S.E.}^2 = \text{Mack.ProcessRisk}^2 + \text{Mack.ParameterRisk}^2$
Total.Mack.S.E	total variability of projected loss for all origin years combined
Total.ProcessRisk	vector of process risk estimate of the total of projected loss for all origin years combined by development period
Total.ParameterRisk	vector of parameter risk estimate of the total of projected loss for all origin years combined by development period
weights	weights used.
alpha	alphas used.
tail	tail factor used. If tail was set to TRUE the output will include the linear model used to estimate the tail factor

**Description**

Mse is a generic function to calculate mean square error estimations in the chain ladder framework.

**Usage**

```
Mse(ModelFit, FullTriangles, ...)

## S4 method for signature 'GMCLFit,triangles'
Mse(ModelFit, FullTriangles, ...)
## S4 method for signature 'MCLFit,triangles'
Mse(ModelFit, FullTriangles, mse.method="Mack", ...)
```

**Arguments**

ModelFit	An object of class "GMCLFit" or "MCLFit".
FullTriangles	An object of class "triangles". Should be the output from a call of predict.
mse.method	Character strings that specify the MSE estimation method. Only works for "MCLFit". Use "Mack" for the generalization of the Mack (1993) approach, and "Independence" for the conditional resampling approach in Merz and Wuthrich (2008).
...	Currently not used.

**Details**

These functions calculate the conditional mean square errors using the recursive formulas in Zhang (2010), which is a generalization of the Mack (1993, 1999) formulas. In the GMCL model, the conditional mean square error for single accident years and aggregated accident years are calculated as:

$$\hat{m}se(\hat{Y}_{i,k+1}|D) = \hat{B}_k \hat{m}se(\hat{Y}_{i,k}|D) \hat{B}_k + (\hat{Y}'_{i,k} \otimes I) \hat{\Sigma}_{B_k} (\hat{Y}_{i,k} \otimes I) + \hat{\Sigma}_{\epsilon_{i_k}}.$$

$$\hat{m}se\left(\sum_{i=a_k}^I \hat{Y}_{i,k+1}|D\right) = \hat{B}_k \hat{m}se\left(\sum_{i=a_k+1}^I \hat{Y}_{i,k}|D\right) \hat{B}_k + \left(\sum_{i=a_k}^I \hat{Y}'_{i,k} \otimes I\right) \hat{\Sigma}_{B_k} \left(\sum_{i=a_k}^I \hat{Y}_{i,k} \otimes I\right) + \sum_{i=a_k}^I \hat{\Sigma}_{\epsilon_{i_k}}.$$

In the MCL model, the conditional mean square error from Merz and Wuthrich (2008) is also available, which can be shown to be equivalent as the following:

$$\hat{m}se(\hat{Y}_{i,k+1}|D) = (\hat{\beta}_k \hat{\beta}'_k) \odot \hat{m}se(\hat{Y}_{i,k}|D) + \hat{\Sigma}_{\beta_k} \odot (\hat{Y}_{i,k} \hat{Y}'_{i,k}) + \hat{\Sigma}_{\epsilon_{i_k}} + \hat{\Sigma}_{\beta_k} \odot \hat{m}se^E(\hat{Y}_{i,k}|D).$$

$$\hat{m}se\left(\sum_{i=a_k}^I \hat{Y}_{i,k+1} | D\right) = (\hat{\beta}_k \hat{\beta}_k') \odot \sum_{i=a_k+1}^I \hat{m}se(\hat{Y}_{i,k} | D) + \hat{\Sigma}_{\beta_k} \odot \left( \sum_{i=a_k}^I \hat{Y}_{i,k} \sum_{i=a_k}^I \hat{Y}'_{i,k} \right) + \sum_{i=a_k}^I \hat{\Sigma}_{\epsilon_{i,k}} + \hat{\Sigma}_{\beta_k} \odot \sum_{i=a_k}^I \hat{m}se^E(\hat{Y}_{i,k} | D).$$

For the Mack approach in the MCL model, the cross-product term  $\hat{\Sigma}_{\beta_k} \odot \hat{m}se^E(\hat{Y}_{i,k} | D)$  in the above two formulas will drop out.

### Value

Mse returns an object of class "MultiChainLadderMse" that has the following elements:

mse.ay	conditional mse for each accdient year
mse.ay.est	conditional estimation mse for each accdient year
mse.ay.proc	conditional process mse for each accdient year
mse.total	conditional mse for aggregated accdient years
mse.total.est	conditional estimation mse for aggregated accdient years
mse.total.proc	conditional process mse for aggregated accdient years
FullTriangles	completed triangles

### Description

The function MultiChainLadder implements multivariate methods to forecast insurance loss payments based on several cumulative claims development triangles. These methods are multivariate extensions of the chain ladder technique, which develop several correlated triangles simultaneously in a way that both contemporaneous correlations and structural relationships can be accounted for. The estimated conditional Mean Square Errors (MSE) are also produced.

**Usage**

```
MultiChainLadder(Triangles, fit.method = "SUR", delta = 1,
  int = NULL, restrict.regMat = NULL, extrap = TRUE,
  mse.method = "Mack", model = "MCL", ...)
```

```
MultiChainLadder2(Triangles, mse.method = "Mack", last = 3,
  type = c("MCL", "MCL+int", "GMCL-int", "GMCL"), ...)
```

**Arguments**

Triangles	a list of cumulative claims triangles of the same dimensions.
fit.method	the method used to fit the multivariate regression in each development period. The default is "SUR" - seemingly unrelated regressions. When "OLS" (Ordinary Least Squares) is used, this is the same as developing each triangle separately.
delta	parameter for controlling weights. It is used to determine the covariance structure $D(Y_{i,k}^{\delta/2})\Sigma_k D(Y_{i,k}^{\delta/2})$ . The default value 1 means that the variance is proportional to the cumulative loss from the previous period.
int	a numeric vector that indicates which development periods have intercepts specified. This only takes effect for model = "GMCL". The default NULL means that no intercepts are specified.
restrict.regMat	a list of matrix specifying parameter restriction matrix for each period. This is only used for model = "GMCL". The default value NULL means no restriction is imposed on the development matrix. For example, if there are 3 triangles, there will be 9 parameters in the development matrix for each period if restrict.regMat = NULL. See systemfit for how to specify the appropriate parameter constraints.
extrap	a logical value indicating whether to use Mack's extrapolation method for the last period to get the residual variance estimation. It only takes effect for model = "MCL". If the data are trapezoids, it is set to be FALSE automatically and a warning message is given.
mse.method	method to estimate the mean square error. It can be either "Mack" or "Independence", which are the multivariate generalization of Mack's formulas and the conditional re-sampling approach, respectively.
model	the structure of the model to be fitted. It is either "MCL" or "GMCL". See details below.
last	an integer. The MultiChainLadder2 function splits the triangles into 2 parts internally (see details below), and the last argument indicates how many of the development periods in the tail go into the second part of the split. The default is 3.
type	the type of the model structure to be specified for the first part of the split model in MultiChainLadder2. "MCL" - the multivariate chain ladder with diagonal development matrix; "MCL+int" - the multivariate chain ladder with additional intercepts; "GMCL-int" - the general multivariate chain ladder without intercepts; and "GMCL" - the full general multivariate chain ladder with intercepts and non-diagonal development matrix.

... arguments passed to `systemfit`.

## Details

This function implements multivariate loss reserving models within the chain ladder framework. Two major models are included. One is the Multivariate Chain Ladder (MCL) model proposed by Prohl and Schmidt (2005). This is a direct multivariate generalization of the univariate chain ladder model in that losses from different triangles are assumed to be correlated but the mean development in one triangle only depends on its past values, not on the observed values from other triangles. In contrast, the other model, the General Multivariate Chain Ladder (GMCL) model outlined in Zhang (2010), extends the MCL model by allowing development dependencies among different triangles as well as the inclusion of regression intercepts. As a result, structurally related triangles, such as the paid and incurred loss triangles or the paid loss and case reserve triangles, can be developed together while still accounting for the potential contemporaneous correlations. While the MCL model is a special case of the GMCL model, it is programmed and listed separately because: a) it is an important model for its own sake; b) different MSE methods are only available for the MCL model; c) extrapolation of the residual variance estimation can be implemented for the MCL model, which is considerably difficult for the GMCL model.

We introduce some details of the GMCL model in the following. Assume  $N$  triangles are available. Denote  $Y_{i,k} = (Y_{i,k}^{(1)}, \dots, Y_{i,k}^{(N)})$  as an  $N \times 1$  vector of cumulative losses at accident year  $i$  and development year  $k$ , where  $(n)$  refers to the  $n$ -th triangle. The GMCL model in development period  $k$  (from development year  $k$  to year  $k+1$ ) is:

$$Y_{i,k+1} = A_k + B_k \cdot Y_{i,k} + \epsilon_{i,k},$$

where  $A_k$  is a column of intercepts and  $B_k$  is the  $N \times N$  development matrix. By default, `MultiChainLadder` sets  $A_k$  to be zero. This behavior can be changed by appropriately specifying the `int` argument. Assumptions for this model are:

$$E(\epsilon_{i,k} | Y_{i,1}, \dots, Y_{i,I+1-k}) = 0.$$

$$\text{cov}(\epsilon_{i,k} | Y_{i,1}, \dots, Y_{i,I+1-k}) = \Sigma_{\epsilon_{i,k}} = D(Y_{i,k}^{\delta/2}) \Sigma_k D(Y_{i,k}^{\delta/2}).$$

losses of different accident years are independent.

$\epsilon_{i,k}$  are symmetrically distributed.

The GMCL model structure is generally over-parameterized. Parameter restrictions are usually necessary for the estimation to be feasible, which can be specified through the `restrict.regMat` argument. We refer the users to the documentation for `systemfit` for details and the demo of the present function for examples.

In particular, if one restricts the development matrix to be diagonal, the GMCL model will reduce to the MCL model. When non-diagonal development matrix is used and the GMCL model is applied to paid and incurred loss triangles, it can reflect the development relationship between the two triangles, as described in Quarg and Mack (2004). The full bivariate model is identical to the "double regression" model described by Mack (2003), which is argued by him to be very similar to the Munich Chain Ladder (MuCL) model. The GMCL model with intercepts can also help improve model adequacy as described in Barnett and Zehnwirth (2000).

Currently, the GMCL model only works for trapezoid data, and only implements `mse.method = "Mack"`. The MCL model allows an additional mse estimation method that assumes independence among the

estimated parameters. Further, the MCL model using `fit.method = "OLS"` will be equivalent to running univariate chain ladders separately on each triangle. Indeed, when only one triangle is specified (as a list), the MCL model is equivalent to `MackChainLadder`.

The GMCL model allows different model structures to be specified in each development period. This is generally achieved through the combination of the `int` argument, which specifies the periods that have intercepts, and the `restrict.regMat` argument, which imposes parameter restrictions on the development matrix.

In using the multivariate methods, we often specify separate univariate chain ladders for the tail periods to stabilize the estimation - there are few data points in the tail and running a multivariate model often produces extremely volatile estimates or even fails. In this case, we can use the subset operator `"["` defined for class `triangles` to split the input data into two parts. We can specify a multivariate model with rich structures on the first part to reflect the multivariate dependencies, and simply apply multiple univariate chain ladders on the second part. The two models are subsequently joined together using the `Join2Fits` function. We can then invoke the `predict` and `Mse` methods to produce loss predictions and mean square error estimations. They can further be combined via the `JoinFitMse` function to construct an object of class `MultiChainLadder`. See the demo for such examples.

To facilitate such a split-and-join process for most applications, we have created the function `MultiChainLadder2`. This function splits the data according to the `last` argument (e.g., if `last = 3`, the last three periods go into the second part), and fits the first part according to the structure indicated in the `type` argument. See the 'Arguments' section for details.

## Value

`MultiChainLadder` returns an object of class `MultiChainLadder` with the following slots:

<code>model</code>	the model structure used, either "MCL" or "GMCL"
<code>Triangles</code>	input triangles of cumulative claims that are converted to class <code>triangles</code> internally.
<code>models</code>	fitted models for each development period. This is the output from the call of <code>systemfit</code> .
<code>coefficients</code>	estimated regression coefficients or development parameters. They are put into the matrix format for the GMCL model.
<code>coefCov</code>	estimated variance-covariance matrix for the regression coefficients.
<code>residCov</code>	estimated residual covariance matrix.
<code>fit.method</code>	multivariate regression estimation method
<code>delta</code>	the value of delta
<code>mse.ay</code>	mean square error matrix for each accident year
<code>mse.ay.est</code>	estimation error matrix for each accident year
<code>mse.ay.proc</code>	process error matrix for each accident year
<code>mse.total</code>	mean square error matrix for all accident years combined
<code>mse.total.est</code>	estimation error matrix for all accident years combined
<code>mse.total.proc</code>	process error matrix for all accident years combined
<code>FullTriangles</code>	the forecasted full triangles of class <code>triangles</code>
<code>int</code>	intercept indicators

**Note**

When MultiChainLadder or MultiChainLadder2 fails, the most possible reason is that there is little or no development in the tail periods. That is, the development factor is 1 or almost equal to 1. In this case, the systemfit function may fail even for fit.method = "OLS", because the residual covariance matrix  $\Sigma_k$  is singular. The simplest solution is to remove these columns using the "[" operator and fit the model on the remaining part.

Also, we recommend the use of MultiChainLadder2 over MultiChainLadder. The function MultiChainLadder2 meets the need for most applications, is relatively easy to use and produces more stable but very similar results to MultiChainLadder. Use MultiChainLadder only when non-standard situation arises, e.g., when different parameter restrictions are needed for different periods. See the demo for such examples.

MultiChainLadder-class

*Class "MultiChainLadder" of Multivariate Chain Ladder Results*

---

## Description

This class includes the first and second moment estimation result using the multivariate reserving methods in chain ladder. Several primitive methods and statistical methods are also created to facilitate further analysis.

## Objects from the Class

Objects can be created by calls of the form `new("MultiChainLadder", ...)`, or they could also be a result of calls from `MultiChainLadder` or `JoinFitMse`.

## Slots

**model:** Object of class "character". Either "MCL" or "GMCL".

**Triangles:** Object of class "triangles". Input triangles.

**models:** Object of class "list". Fitted regression models using `systemfit`.

**coefficients:** Object of class "list". Estimated regression coefficients.

**coefCov:** Object of class "list". Estimated variance-covariance matrix of coefficients.

**residCov:** Object of class "list". Estimated residual covariance matrix.

**fit.method:** Object of class "character". Could be values of "SUR" or "OLS".

**delta:** Object of class "numeric". Parameter for weights.

**int:** Object of class "NullNum". Indicator of which periods have intercepts.

**mse.ay:** Object of class "matrix". Conditional mse for each accident year.

**mse.ay.est:** Object of class "matrix". Conditional estimation mse for each accident year.  
**mse.ay.proc:** Object of class "matrix". Conditional process mse for each accident year.  
**mse.total:** Object of class "matrix". Conditional mse for aggregated accident years.  
**mse.total.est:** Object of class "matrix". Conditional estimation mse for aggregated accident years.  
**mse.total.proc:** Object of class "matrix". Conditional process mse for aggregated accident years.  
**FullTriangles:** Object of class "triangles". Completed triangles.  
**restrict.regMat:** Object of class "NullList"

### Extends

Class "MultiChainLadderFit", directly. Class "MultiChainLadderMse", directly.

### Methods

**\$** signature(x = "MultiChainLadder"): Method for primitive function "\$". It extracts a slot of x with a specified slot name, just as in list.  
**[[** signature(x = "MultiChainLadder", i = "numeric", j = "missing"): Method for primitive function "[[". It extracts the i-th slot of a "MultiChainLadder" object, just as in list. i could be a vector.  
**[[** signature(x = "MultiChainLadder", i = "character", j = "missing"): Method for primitive function "[[". It extracts the slots of a "MultiChainLadder" object with names in i, just as in list. i could be a vector.  
**coef** signature(object = "MultiChainLadder"): Method for function coef, to extract the estimated development matrix. The output is a list.  
**fitted** signature(object = "MultiChainLadder"): Method for function fitted, to calculate the fitted values in the original triangles. Note that the return value is a list of fitted valued based on the original scale, not the model scale which is first divided by  $Y_{i,k}^{\delta/2}$ .  
**names** signature(x = "MultiChainLadder"): Method for function names, which returns the slot names of a "MultiChainLadder" object.  
**plot** signature(x = "MultiChainLadder", y = "missing"): See [plot, MultiChainLadder, missing-method](#).  
**residCov** signature(object = "MultiChainLadder"): S4 generic function and method to extract residual covariance from a "MultiChainLadder" object.  
**residCor** signature(object = "MultiChainLadder"): S4 generic function and method to extract residual correlation from a "MultiChainLadder" object.  
**residuals** signature(object = "MultiChainLadder"): Method for function residuals, to extract residuals from a system of regression equations. These residuals are based on model scale, and will not be equivalent to those on the original scale if  $\delta$  is not set to be 0. One should use rstandard instead, which is independent of the scale.  
**resid** signature(object = "MultiChainLadder"): Same as residuals.  
**rstandard** signature(model = "MultiChainLadder"): S4 generic function and method to extract standardized residuals from a "MultiChainLadder" object.

**show** signature(object = "MultiChainLadder"): Method for show.

**summary** signature(object = "MultiChainLadder"): See [summary, MultiChainLadder-method](#).

**vcov** signature(object = "MultiChainLadder"): Method for function vcov, to extract the variance-covariance matrix of a "MultiChainLadder" object. Note that the result is a list of Bcov, that is the variance-covariance matrix of the vectorized  $B$ .

head(do.call("rbind",rstandard(fit.liab)))
```

---

MultiChainLadderFit-class

*Class "MultiChainLadderFit", "MCLFit" and "GMCLFit"*

---

### Description

"MultiChainLadderFit" is a virtual class for the fitted models in the multivariate chain ladder reserving framework, "MCLFit" is a result from the internal call `.FitMCL` to store results in model MCL and "GMCLFit" is a result from the internal call `.FitGMCL` to store results in model GMCL. The two classes "MCLFit" and "GMCLFit" differ only in the presentation of  $B_k$  and  $\Sigma_{B_k}$ , and different methods of `Mse` and `predict` will be dispatched according to these classes.

### Objects from the Class

"MultiChainLadderFit" is a virtual Class: No objects may be created from it. For "MCLFit" and "GMCLFit", objects can be created by calls of the form `new("MCLFit", ...)` and `new("GMCLFit", ...)` respectively.

**Slots**

Triangles: Object of class "triangles"  
models: Object of class "list"  
B: Object of class "list"  
Bcov: Object of class "list"  
ecov: Object of class "list"  
fit.method: Object of class "character"  
delta: Object of class "numeric"  
int: Object of class "NullNum"  
restrict.regMat: Object of class "NullList"

**Extends**

"MCLFit" and "GMCLFit" extends class "[MultiChainLadderFit](#)", directly.

**Methods**

No methods defined with class "MultiChainLadderFit" in the signature.

For "MCLFit", the following methods are defined:

Mse signature(ModelFit = "MCLFit", FullTriangles = "triangles"): Calculate Mse estimations.

predict signature(object = "MCLFit"): Predict ultimate losses and complete the triangles. The output is an object of class "triangles".

For "GMCLFit", the following methods are defined:

Mse signature(ModelFit = "GMCLFit", FullTriangles = "triangles"): Calculate Mse estimations.

predict signature(object = "GMCLFit"): Predict ultimate losses and complete the triangles. The output is an object of class "triangles".

```

---

MultiChainLadderMse-class

*Class "MultiChainLadderMse"*

---

### Description

This class is used to define the structure in storing the MSE results.

### Objects from the Class

Objects can be created by calls of the form `new("MultiChainLadderMse", ...)`, or as a result of a call to `Mse`.

### Slots

`mse.ay`: Object of class "matrix"  
`mse.ay.est`: Object of class "matrix"  
`mse.ay.proc`: Object of class "matrix"  
`mse.total`: Object of class "matrix"  
`mse.total.est`: Object of class "matrix"  
`mse.total.proc`: Object of class "matrix"  
`FullTriangles`: Object of class "triangles"

### Methods

No methods defined with class "MultiChainLadderMse" in the signature.

### Author(s)

showClass("MultiChainLadderMse")
```

---

MultiChainLadderSummary-class  
*Class "MultiChainLadderSummary"*

---

### Description

This class stores the summary statistics from a "MultiChainLadder" object. These summary statistics include both model summary and report summary.

### Objects from the Class

Objects can be created by calls of the form `new("MultiChainLadderSummary", ...)`, or a call from `summary`.

### Slots

Triangles: Object of class "triangles"  
FullTriangles: Object of class "triangles"  
S.E.Full: Object of class "list"  
S.E.Est.Full: Object of class "list"  
S.E.Proc.Full: Object of class "list"  
Ultimate: Object of class "matrix"  
IBNR: Object of class "matrix"  
S.E.Ult: Object of class "matrix"  
S.E.Est.Ult: Object of class "matrix"  
S.E.Proc.Ult: Object of class "matrix"  
report.summary: Object of class "list"  
coefficients: Object of class "list"  
coefCov: Object of class "list"  
residCov: Object of class "list"  
rstandard: Object of class "matrix"  
fitted.values: Object of class "matrix"  
residCor: Object of class "matrix"  
model.summary: Object of class "matrix"  
portfolio: Object of class "NullChar"

**Methods**

**\$** signature(x = "MultiChainLadderSummary"): Method for primitive function "\$". It extracts a slot of x with a specified slot name, just as in list.

**[[** signature(x = "MultiChainLadderSummary", i = "numeric", j = "missing"): Method for primitive function "[[". It extracts the i-th slot of a "MultiChainLadder" object, just as in list. i could be a vector.

**[[** signature(x = "MultiChainLadderSummary", i = "character", j = "missing"): Method for primitive function "[[". It extracts the slots of a "MultiChainLadder" object with names in i, just as in list. i could be a vector.

**names** signature(x = "MultiChainLadderSummary"): Method for function names, which returns the slot names of a "MultiChainLadder" object.

**show** signature(object = "MultiChainLadderSummary"): Method for show.

**Author(s)**

**Examples**

```
showClass("MultiChainLadderSummary")
```

---

MunichChainLadder      *Munich-chain-ladder Model*

---

**Description**

The Munich-chain-ladder model forecasts ultimate claims based on a cumulative paid and incurred claims triangle. The model assumes that the Mack-chain-ladder model is applicable to the paid and incurred claims triangle, see [MackChainLadder](#).

**Usage**

```
MunichChainLadder(Paid, Incurred,
                  est.sigmaP = "log-linear", est.sigmaI = "log-linear",
                  tailP=FALSE, tailI=FALSE)
```

**Arguments**

Paid	cumulative paid claims triangle. Assume columns are the development period, use transpose otherwise. A (mxn)-matrix $P_{ik}$ which is filled for $k \leq n + 1 - i; i = 1, \dots, m; m \geq n$
Incurred	cumulative incurred claims triangle. Assume columns are the development period, use transpose otherwise. A (mxn)-matrix $I_{ik}$ which is filled for $k \leq n + 1 - i; i = 1, \dots, m; m \geq n$
est.sigmaP	defines how $\sigma_{n-1}$ for the Paid triangle is estimated, see est.sigma in <a href="#">MackChainLadder</a> for more details, as est.sigmaP gets passed on to MackChainLadder
est.sigmaI	defines how $\sigma_{n-1}$ for the Incurred triangle is estimated, see est.sigma in <a href="#">MackChainLadder</a> for more details, as est.sigmaI is passed on to MackChainLadder
tailP	defines how the tail of the Paid triangle is estimated and is passed on to <a href="#">MackChainLadder</a> , see tail just there.
tailI	defines how the tail of the Incurred triangle is estimated and is passed on to <a href="#">MackChainLadder</a> , see tail just there.

**Value**

MunichChainLadder returns a list with the following elements

call	matched call
Paid	input paid triangle
Incurred	input incurred triangle
MCLPaid	Munich-chain-ladder forecasted full triangle on paid data
MCLIncurred	Munich-chain-ladder forecasted full triangle on incurred data
MackPaid	Mack-chain-ladder output of the paid triangle
MackIncurred	Mack-chain-ladder output of the incurred triangle
PaidResiduals	paid residuals
IncurredResiduals	incurred residuals
QResiduals	paid/incurred residuals
QinverseResiduals	incurred/paid residuals
lambdaP	dependency coefficient between paid chain ladder age-to-age factors and incurred/paid age-to-age factors
lambdaI	dependency coefficient between incurred chain ladder ratios and paid/incurred ratios
qinverse.f	chain-ladder-link age-to-age factors of the incurred/paid triangle
rhoP.sigma	estimated conditional deviation around the paid/incurred age-to-age factors
q.f	chain-ladder age-to-age factors of the paid/incurred triangle
rhoI.sigma	estimated conditional deviation around the incurred/paid age-to-age factors

---

NullNum-class                    *Class "NullNum", "NullChar" and "NullList"*

---

### Description

Virtual class for `c("null", "numeric")`, `c("null", "character")` and `c("null", "list")`

### Objects from the Class

A virtual Class: No objects may be created from it.

### Methods

No methods defined with class "NullNum" in the signature.

---

plot-MultiChainLadder    *Methods for Function plot*

---

### Description

Methods for function plot to produce different diagnostic plots for an object of class "MultiChainLadder".

### Usage

```

## S4 method for signature 'MultiChainLadder,missing'
plot(x, y, which.plot=1:4,
     which.triangle=NULL,
     main=NULL,
     portfolio=NULL,
     lowess=TRUE,
     legend.cex=0.75,...)

```

**Arguments**

x	An object of class "MultiChainLadder".
y	"missing"
which.plot	This specifies which type of plot is desired. Its range is 1:5, but defaults to 1:4. "1" is the barplot of observed losses and predicted IBNR stacked and MSE predictions as error bars; "2" is a trajectory plot of the development pattern; "3" is the residual plot of standardized residuals against the fitted values; "4" is the Normal-QQ plot of the standardized residuals. "5" is the "xyplot" of development with confidence intervals for each accident year. Note that "3" and "4" are not available for portfolio.
which.triangle	This specifies which triangles are to be plotted. Default value is NULL, where all triangles plus the portfolio result will be plotted.
main	It should be a list of titles for each plot. If not supplied, use default titles.
portfolio	It specifies which triangles are to be summed as the portfolio, to be passed on to summary.
lowess	Logical. If TRUE, smoothing lines will be added on residual plots.
legend.cex	plotting parameter to be passes on to cex in legend if which.plot=1.
...	optional graphical arguments.

**Examples**

```
## Not run:
data(liab)
fit.liab <- MultiChainLadder(liab)

# generate diagnostic plots
par(mfcol=c(3,2))
plot(fit.liab,which.plot=1:2)

par(mfrow=c(2,2))
plot(fit.liab,which.plot=3:4)

plot(fit.liab,which.triangle=1,which.plot=5)
graphics.off()

## End(Not run)
```

---

plot.BootChainLadder *Plot method for a BootChainLadder object*

---

### Description

plot.BootChainLadder, a method to plot the output of [BootChainLadder](#). It is designed to give a quick overview of a BootChainLadder object and to check the model assumptions.

### Usage

```
## S3 method for class 'BootChainLadder'  
plot(x, mfrow=c(2,2), title=NULL, log=FALSE, ...)
```

### Arguments

x	output from BootChainLadder
mfrow	see <a href="#">par</a>
title	see <a href="#">title</a>
log	logical. If TRUE the y-axes of the 'latest incremental actual vs. simulated' plot will be on a log-scale
...	optional arguments. See <a href="#">plot.default</a> for more details.

### Details

plot.BootChainLadder shows four graphs, starting with a histogram of the total simulated IBNRs over all origin periods, including a rug plot; a plot of the empirical cumulative distribution of the total IBNRs over all origin periods; a box-whisker plot of simulated ultimate claims costs against origin periods; and a box-whisker plot of simulated incremental claims cost for the latest available calendar period against actual incremental claims of the same period. In the last plot the simulated data should follow the same trend as the actual data, otherwise the original data might have some intrinsic trends which are not reflected in the model.

### Note

The box-whisker plot of latest actual incremental claims against simulated claims follows is based on ideas from Barnett and Zehnwirth in: *Barnett and Zehnwirth. The need for diagnostic assessment of bootstrap predictive models*, Insureware technical report. 2007

plot(B)
plot(B, log=TRUE)
```

---

`plot.clark`*Plot Clark method residuals*

---

**Description**

Function to plot the residuals of the Clark LDF and Cape Cod methods.

**Usage**

```
## S3 method for class 'clark'
plot(x, ...)
```

**Arguments**

`x` object resulting from a run of the ClarkLDF or ClarkCapeCod functions.  
`...` not used.

**Details**

If Clark's model is appropriate for the actual data, then the standardized residuals should appear as independent standard normal random variables. This function creates four plots of standardized residuals on a single page:

1. By origin
2. By age
3. By fitted value
4. Normal Q-Q plot with results of Shapiro-Wilk test

If the model is appropriate then there should not appear to be any trend in the standardized residuals or any systematic differences in the spread about the line  $y = 0$ . The Shapiro-Wilk p-value shown in the fourth plot gives an indication of how closely the standardized residuals can be considered "draws" from a standard normal random variable.

**Examples**

```
X <- GenIns
Y <- ClarkLDF(GenIns, maxage=Inf, G="weibull")
plot(Y) # One obvious outlier, shapiro test flunked
X[4,4] <- NA # remove the outlier
Z <- ClarkLDF(GenIns, maxage=Inf, G="weibull")
plot(Z) # Q-Q plot looks good
```

---

plot.MackChainLadder *Plot method for a MackChainLadder object*

---

**Description**

plot.MackChainLadder, a method to plot the output of [MackChainLadder](#). It is designed to give a quick overview of a MackChainLadder object and to check Mack's model assumptions.

**Usage**

```
## S3 method for class 'MackChainLadder'
plot(x, mfrow=c(3,2), title=NULL, lattice=FALSE,...)
```

**Arguments**

x	output from MackChainLadder
mfrow	see <a href="#">par</a>
title	see <a href="#">title</a>
lattice	logical. Default is set to FALSE and plots as described in the details section are produced. If lattice=TRUE, the function <a href="#">xyplot</a> of the lattice package is used to plot developments by origin period in different panels, plus Mack's S.E.
...	optional arguments. See <a href="#">plot.default</a> for more details.

**Details**

plot.MackChainLadder shows six graphs, starting from the top left with a stacked bar-chart of the latest claims position plus IBNR and Mack's standard error by origin period; next right to it is a plot of the forecasted development patterns for all origin periods (numbered, starting with 1 for the oldest origin period), and 4 residual plots. The residual plots show the standardised residuals against fitted values, origin period, calendar period and development period. All residual plot should show no patterns or directions for Mack's method to be applicable. Pattern in any direction can be the result of trends and should be further investigated, see *Barnett and Zehnwirth. Best estimates for reserves. Proceedings of the CAS, LXXXVII(167), November 2000.* for more details on trends.

plot.MunichChainLadder
```

*Plot method for a MunichChainLadder object*

---

**Description**

`plot.MunichChainLadder`, a method to plot the output of [MunichChainLadder](#) object. It is designed to give a quick overview of a `MunichChainLadder` object and to check the correlation between the paid and incurred residuals.

**Usage**

```
## S3 method for class 'MunichChainLadder'  
plot(x, mfrow=c(2,2), title=NULL, ...)
```

**Arguments**

<code>x</code>	output from <code>MunichChainLadder</code>
<code>mfrow</code>	see <a href="#">par</a>
<code>title</code>	see <a href="#">title</a>
<code>...</code>	optional arguments. See <a href="#">plot.default</a> for more details.

**Details**

`plot.MunichChainLadder` shows four plots, starting from the top left with a barchart of forecasted ultimate claims costs by Munich-chain-ladder (MCL) on paid and incurred data by origin period; the barchart next to it compares the ratio of forecasted ultimate claims cost on paid and incurred data based on the Mack-chain-ladder and Munich-chain-ladder methods; the two residual plots at the bottom show the correlation of (incurred/paid)-chain-ladder factors against the paid-chain-ladder factors and the correlation of (paid/incurred)-chain-ladder factors against the incurred-chain-ladder factors.

**Note**

The design of the plots follows those in Quarg's (2004) paper: *Gerhard Quarg and Thomas Mack. Munich Chain Ladder. Blatter DGVFM 26, Munich, 2004.*

**Author(s)**

Markus Gesmann

M <- MunichChainLadder(MCLpaid, MCLincurred)
plot(M)
```

---

predict.TriangleModel *Prediction of a claims triangle*

---

**Description**

The function is internally used by [MackChainLadder](#) to forecast future claims.

**Usage**

```
## S3 method for class 'TriangleModel'
predict(object,...)
## S3 method for class 'ChainLadder'
predict(object,...)
```

**Arguments**

object	a list with two items: Models, Triangle
	Models list of linear models for each development period
	Triangle input triangle to forecast
...	not in use

**Value**

FullTriangle forecasted claims triangle

**Author(s)**

Markus Gesmann

**See Also**

See also [chainladder](#), [MackChainLadder](#)

**Examples**

```
RAA
CL <- chainladder(RAA)
CL
predict(CL)
```

---

print.ata	<i>Print Age-to-Age factors</i>
-----------	---------------------------------

---

**Description**

Function to print the results of a call to the `ata` function.

**Usage**

```
## S3 method for class 'ata'
print(x, ...)
```

**Arguments**

x	object resulting from a call to the <a href="#">ata</a> function
...	further arguments passed to <code>print</code>

**Details**

`print.ata` simply prints [summary.ata](#).

**Value**

A `summary.ata` matrix, invisibly.

**Author(s)**

Daniel Murphy

**See Also**

[ata](#) and [summary.ata](#)

**Examples**

```
x <- ata(GenIns)

## Print ata factors rounded to 3 decimal places, the summary.ata default
print(x)

## Round to 4 decimal places and print cells corresponding
## to future observations as blanks.
print(summary(x, digits=4), na.print="")
```

---

```
print.clark          Print results of Clark methods
```

---

**Description**

Functions to print the results of the ClarkLDF and ClarkCapeCod methods.

**Usage**

```
## S3 method for class 'ClarkLDF'
print(x, Amountdigits=0, LDFdigits=3, CVdigits=3,
      row.names = FALSE, ...)

## S3 method for class 'ClarkCapeCod'
print(x, Amountdigits=0, ELRdigits=3, Gdigits=4, CVdigits=3,
      row.names = FALSE, ...)
```

**Arguments**

x	object resulting from a run of the ClarkLDF or ClarkCapeCod function.
Amountdigits	number of digits to display to the right of the decimal point for "amount" columns
LDFdigits	number of digits to display to the right of the decimal point for the loss development factor (LDF) column
CVdigits	number of digits to display to the right of the decimal point for the coefficient of variation (CV) column
ELRdigits	number of digits to display to the right of the decimal point for the expected loss ratio (ELR) column
Gdigits	number of digits to display to the right of the decimal point for the "growth function factor" column; default of 4 conforms with the table on pp. 67, 68 of Clark's paper
row.names	logical (or character vector), indicating whether (or what) row names should be printed (same as for <a href="#">print.data.frame</a> )
...	further arguments passed to print

**Details**

Display the default information in "pretty format" resulting from a run of the "LDF Method" or "Cape Cod Method" – a "Development-type" exhibit for Clark's "LDF Method," a "Bornhuetter-Ferguson-type" exhibit for Clark's "Cape Cod Method."

As usual, typing the name of such an object at the console invokes its print method.

**Value**

data.frames whose columns are the character representation of their respective [summary.ClarkLDF](#) or [summary.ClarkCapeCod](#) data.frames.

**Author(s)**

Daniel Murphy

**References**

Clark, David R., "LDF Curve-Fitting and Stochastic Reserving: A Maximum Likelihood Approach", *Casualty Actuarial Society Forum*, Fall, 2003

**Examples**

```
X <- GenIns
colnames(X) <- 12*as.numeric(colnames(X))
y <- ClarkCapeCod(X, Premium=10000000+400000*0:9, maxage=240)
summary(y)
print(y) # (or simply 'y') Same as summary(y) but with "pretty formats"

## Greater growth factors when projecting to infinite maximum age
ClarkCapeCod(X, Premium=10000000+400000*0:9, maxage=Inf)
```

---

qpaid

*Quarterly run off triangle of accumulated claims data*

---

**Description**

Sample data to demonstrate how to work with triangles with a higher development period frequency than origin period frequency

**Usage**

```
data(qpaid); data(qincurred)
```

**Format**

A matrix with 12 accident years and 45 development quarters of claims costs.

**Source**

Made up data for testing purpose

**Examples**

```
dim(qpaid)
dim(qincurred)
op=par(mfrow=c(1,2))
ymax <- max(c(qpaid,qincurred),na.rm=TRUE)*1.05
matplot(t(qpaid), type="l", main="Paid development",
        xlab="Dev. quarter", ylab="$", ylim=c(0,ymax))
matplot(t(qincurred), type="l", main="Incurred development",
        xlab="Dev. quarter", ylab="$", ylim=c(0,ymax))
par(op)
## MackChainLadder expects a quadratic matrix so let's expand
## the triangle to a quarterly origin period.
n <- ncol(qpaid)
Paid <- matrix(NA, n, n)
Paid[seq(1,n,4),] <- qpaid
M <- MackChainLadder(Paid)
plot(M)

# We expand the incurred triangle in the same way
Incurred <- matrix(NA, n, n)
Incurred[seq(1,n,4),] <- qincurred

# With the expanded triangles we can apply MunichChainLadder
MunichChainLadder(Paid, Incurred)

# In the same way we can apply BootChainLadder
# We reduce the size of bootstrap replicates R
# from the default of 999 to 99 purely to reduce run time.
BootChainLadder(Paid, R=99)
```

---

RAA

*Run off triangle of accumulated claims data*

---

**Description**

Run-off triangle of Automatic Factultative business in General Liability

**Usage**

data(RAA)

**Format**

A matrix with 10 accident years and 10 development years.

residCov

*Generic function for residCov and residCor*

---

**Description**

residCov and residCor are a generic functions to extract residual covariance and residual correlation from a system of fitted regressions respectively.

**Usage**

```
residCov(object,...)
residCor(object,...)

## S4 method for signature 'MultiChainLadder'
residCov(object,...)
## S4 method for signature 'MultiChainLadder'
residCor(object,...)
```

**Arguments**

object            An object of class "MultiChainLadder".  
...                Currently not used.

**Author(s)**

Wayne Zhang <actuary\_zhang@hotmail.com>

**See Also**

See also [MultiChainLadder](#).

---

residuals.MackChainLadder

*Extract residuals of a MackChainLadder model*

---

**Description**

Extract residuals of a [MackChainLadder](#) model by origin-, calendar- and development period.

**Usage**

```
## S3 method for class 'MackChainLadder'  
residuals(object, ...)
```

**Arguments**

object	output of <a href="#">MackChainLadder</a>
...	not in use

**Value**

The function returns a data.frame of residuals and standardised residuals by origin-, calendar- and development period.

**Author(s)**

Markus Gesmann

**See Also**

See Also [MackChainLadder](#)

**Examples**

```
RAA  
MCL=MackChainLadder(RAA)  
MCL  
  
residuals(MCL)
```

summary-methods

*Methods for Function summary***Description**

Methods for function summary to calculate summary statistics from a "MultiChainLadder" object.

**Usage**

```
## S4 method for signature 'MultiChainLadder'
summary(object, portfolio=NULL,...)
```

**Arguments**

object	object of class "MultiChainLadder"
portfolio	character strings specifying which triangles to be summed up as portfolio.
...	optional arguments to summary methods

**Details**

summary calculations the summary statistics for each triangle and the whole portfolio from portfolio. portfolio defaults to the sum of all input triangles. It can also be specified as "i+j" format, which means the sum of the i-th and j-th triangle as portfolio. For example, "1+3" means the sum of the first and third triangle as portfolio.

**Value**

The summary function returns an object of class "MultiChainLadderSummary" that has the following slots:

Triangles	input triangles
FullTriangles	predicted triangles
S.E.Full	a list of prediction errors for each cell
S.E.Est.Full	a list of estimation errors for each cell
S.E.Proc.Full	a list of process errors for each cell
Ultimate	predicted ultimate losses for each triangle and portfolio
Latest	latest observed losses for each triangle and portfolio
IBNR	predicted IBNR for each triangle and portfolio
S.E.Ult	a matrix of prediction errors of ultimate losses for each triangle and portfolio
S.E.Est.Ult	a matrix of estimation errors of ultimate losses for each triangle and portfolio
S.E.Proc.Ult	a matrix of process errors of ultimate losses for each triangle and portfolio
report.summary	summary statistics for each triangle and portfolio

coefficients	estimated coefficients from systemfit. They are put into the matrix format for GMCL
coefCov	estimated variance-covariance matrix returned by systemfit
residCov	estimated residual covariance matrix returned by systemfit
rstandard	standardized residuals
fitted.values	fitted.values
residCor	residual correlation
model.summary	summary statistics for the coefficients including p-values
portfolio	how portfolio is calculated

**Author(s)**

Wayne Zhang <actuary\_zhang@hotmail.com>

**See Also**

See Also [MultiChainLadder](#)

**Examples**

```
data(GenIns)
fit.bbmw=MultiChainLadder(list(GenIns),fit.method="OLS", mse.method="Independence")
summary(fit.bbmw)
```

---

summary.ata

*Summary method for object of class 'ata'*

---

**Description**

Summarize the age-to-age factors resulting from a call to the [ata](#) function.

**Usage**

```
## S3 method for class 'ata'
summary(object, digits=3, ...)
```

**Arguments**

object	object resulting from a call to <a href="#">ata</a>
digits	integer indicating the number of decimal places for rounding the factors. The default is 3. NULL indicates that rounding should take place.
...	not used

## Details

A call to [ata](#) produces a matrix of age-to-age factors with two attributes – the simple and volume weighted averages. `summary.ata` creates a new matrix with the averages appended as rows at the bottom.

## Value

A matrix.

## Author(s)

Dan Murphy

## See Also

See also [ata](#) and [print.ata](#)

## Examples

```
y <- ata(RAA)
summary(y, digits=4)
```

---

summary.BootChainLadder

*Methods for BootChainLadder objects*

---

## Description

summary, print, mean, and quantile methods for BootChainLadder objects

## Usage

```
## S3 method for class 'BootChainLadder'
summary(object, probs=c(0.75,0.95), ...)

## S3 method for class 'BootChainLadder'
print(x, probs=c(0.75,0.95), ...)

## S3 method for class 'BootChainLadder'
quantile(x, probs=c(0.75, 0.95), na.rm = FALSE,
         names = TRUE, type = 7,...)

## S3 method for class 'BootChainLadder'
mean(x, ...)

## S3 method for class 'BootChainLadder'
residuals(object, ...)
```

**Arguments**

x, object	output from <a href="#">BootChainLadder</a>
probs	numeric vector of probabilities with values in [0,1], see <a href="#">quantile</a> for more help
na.rm	logical; if true, any NA and NaN's are removed from 'x' before the quantiles are computed, see <a href="#">quantile</a> for more help
names	logical; if true, the result has a names attribute. Set to FALSE for speedup with many 'probs', see <a href="#">quantile</a> for more help
type	an integer between 1 and 9 selecting one of the nine quantile algorithms detailed below to be used, see <a href="#">quantile</a>
...	further arguments passed to or from other methods

**Details**

print.BootChainLadder calls summary.BootChainLadder and prints a formatted version of the summary. residuals.BootChainLadder gives the residual triangle of the expected chain-ladder minus the actual triangle back.

**Value**

summary.BootChainLadder, mean.BootChainLadder, and quantile.BootChainLadder, give a list with two elements back:

ByOrigin	data frame with summary/mean/quantile statistics by origin period
Totals	data frame with total summary/mean/quantile statistics for all origin period

**Author(s)**

Markus Gesmann

**See Also**

See also [BootChainLadder](#)

**Examples**

```
B <- BootChainLadder(RAA, R=999, process.distr="gamma")
B
summary(B)
mean(B)
quantile(B, c(0.75,0.95,0.99, 0.995))
```

---

`summary.clark`*Summary methods for Clark objects*

---

## Description

summary methods for `ClarkLDF` and `ClarkCapeCod` objects

## Usage

```
## S3 method for class 'ClarkLDF'  
summary(object, ...)
```

```
## S3 method for class 'ClarkCapeCod'  
summary(object, ...)
```

## Arguments

<code>object</code>	object resulting from a run of the <a href="#">ClarkLDF</a> or <a href="#">ClarkCapeCod</a> functions.
<code>...</code>	not currently used

## Details

`summary.ClarkLDF` returns a `data.frame` that holds the columns of a typical "Development-type" exhibit.

`summary.ClarkCapeCod` returns a `data.frame` that holds the columns of a typical "Bornhuetter-Ferguson-type" exhibit.

## Value

`summary.ClarkLDF` and `summary.ClarkCapeCod` return `data.frames` whose columns are objects of the appropriate mode (i.e., character for "Origin", otherwise numeric)

## Author(s)

Dan Murphy

## See Also

See also [ClarkLDF](#)

## Examples

```
y <- ClarkLDF(RAA)  
summary(y)
```

---

`summary.MackChainLadder`*Summary and print function for Mack-chain-ladder*

---

**Description**

summary and print methods for a MackChainLadder object

**Usage**

```
## S3 method for class 'MackChainLadder'  
summary(object, ...)
```

```
## S3 method for class 'MackChainLadder'  
print(x, ...)
```

**Arguments**

<code>x, object</code>	object of class "MackChainLadder"
<code>...</code>	optional arguments to print or summary methods

**Details**

`print.MackChainLadder` calls `summary.MackChainLadder` and prints a formatted version of the summary.

**Value**

`summary.MackChainLadder` gives a list of two elements back

<code>ByOrigin</code>	data frame with Latest (latest actual claims costs), Dev.To.Date (chain-ladder development to date), Ultimate (estimated ultimate claims cost), IBNR (estimated IBNR), Mack.S.E (Mack's estimation of the standard error of the IBNR), and CV(IBNR) (Coefficient of Variance=Mack.S.E/IBNR)
-----------------------	---

<code>Totals</code>	data frame of totals over all origin periods. The items follow the same naming convention as in <code>ByOrigin</code> above
---------------------	---

**Author(s)**

Markus Gesmann

**See Also**

See also [MackChainLadder](#), [plot.MackChainLadder](#)

summary.MunichChainLadder
```

*Summary and print function for Munich-chain-ladder*

---

**Description**

summary and print methods for a MunichChainLadder object

**Usage**

```
## S3 method for class 'MunichChainLadder'
summary(object, ...)

## S3 method for class 'MunichChainLadder'
print(x, ...)
```

**Arguments**

x, object	object of class "MunichChainLadder"
...	optional arguments to print or summary methods

**Details**

print.MunichChainLadder calls summary.MunichChainLadder and prints a formatted version of the summary.

**Value**

summary.MunichChainLadder gives a list of two elements back

ByOrigin	data frame with <i>Latest Paid</i> (latest actual paid claims costs), <i>Latest Incurred</i> (latest actual incurred claims position), <i>Latest P/I Ratio</i> (ratio of latest paid/incurred claims), <i>Ult. Paid</i> (estimate ultimate claims cost based on the paid triangle), <i>Ult. Incurred</i> (estimate ultimate claims cost based on the incurred triangle), <i>Ult. P/I Ratio</i> (ratio of ultimate paid forecast / ultimate incurred forecast)
Totals	data frame of totals over all origin periods. The items follow the same naming convention as in ByOrigin above

**Author(s)**

Markus Gesmann

**See Also**

---

Table65

*Functions to Reproduce Clark's Tables*

---

**Description**

Print the tables on pages 64, 65, and 68 of Clark's paper.

**Usage**

```
Table64(x)
Table65(x)
Table68(x)
```

**Arguments**

x                    an object resulting from `ClarkLDF` or `ClarkCapeCod`

**Details**

These exhibits give some of the details behind the calculations producing the estimates of future values (a.k.a. "Reserves" in Clark's paper). Table65 works for both the "LDF" and the "CapeCod" methods. Table64 is specific to "LDF", Table68 to "CapeCod".

**Value**

A data.frame.

**Author(s)**

Daniel Murphy

**References**

Clark, David R., "LDF Curve-Fitting and Stochastic Reserving: A Maximum Likelihood Approach", *Casualty Actuarial Society Forum*, Fall, 2003 <http://www.casact.org/pubs/forum/03fforum/03ff041.pdf>

**Examples**

```

Table65(ClarkLDF(GenIns, maxage=20))
Table64(ClarkLDF(GenIns, maxage=20))

X <- GenIns
colnames(X) <- 12*as.numeric(colnames(X))
Table65(ClarkCapeCod(X, Premium=10000000+400000*0:9, maxage=Inf))
Table68(ClarkCapeCod(X, Premium=10000000+400000*0:9, maxage=Inf))

```

---

triangle S3 Methods     *Generic functions for triangles*

---

**Description**

Functions to ease the work with triangle shaped matrix data. A 'triangle' is a matrix with some generic functions. Triangles are usually stored in a 'long' format in data bases. The function `as.triangle` can transform a `data.frame` into a triangle shape.

**Usage**

```

## S3 method for class 'matrix'
as.triangle(Triangle,origin="origin", dev="dev", value="value",...)
## S3 method for class 'data.frame'
as.triangle(Triangle, origin="origin", dev="dev", value="value",...)
## S3 method for class 'triangle'
as.data.frame(x, row.names=NULL, optional, lob=NULL, na.rm=FALSE, ...)
as.triangle(Triangle, origin="origin", dev="dev", value="value",...)
## S3 method for class 'triangle'
plot(x, type = "b", xlab = "dev. period", ylab = NULL, lattice=FALSE, ...)

```

**Arguments**

Triangle	a triangle
origin	name of the origin period, default is "origin".
dev	name of the development period, default is "dev".
value	name of the value, default is "value".
row.names	default is set to NULL an will merge origin and dev. period to create row names.
lob	default is NULL. The idea is to use lob (line of business) as an additional column to label a triangle in a long format, see the examples for more details.
optional	not used
na.rm	logical. Remove missing values?
x	a matrix of class 'triangle'
xlab	a label for the x axis, defaults to 'dev. period'

ylab	a label for the y axis, defaults to NULL
lattice	logical. If FALSE the function <code>matplot</code> is used to plot the developments of the triangle in one graph, otherwise the <code>xyplot</code> function of the lattice package is used, to plot developments of each origin period in a different panel.
type	type, see <code>plot.default</code>
...	arguments to be passed to other methods

**Warning**

Please note that for the function `as.triangle` the origin and dev. period columns have to be of type numeric or a character which can be converted into numeric.

Also note that when converting from a data.frame to a matrix with `as.triangle`, multiple records with the same origin and dev will be aggregated.

**Author(s)**

Markus Gesmann, Dan Murphy

**Examples**

```
GenIns
plot(GenIns)
plot(GenIns, lattice=TRUE)

## Convert long format into triangle
## Triangles are usually stored as 'long' tables in data bases
head(GenInsLong)
as.triangle(GenInsLong, origin="accyear", dev="devyear", "incurred claims")

X <- as.data.frame(RAA)
head(X)

Y <- as.data.frame(RAA, lob="General Liability")
head(Y)
```

---

triangles-class	<i>S4 Class "triangles"</i>
-----------------	-----------------------------

---

**Description**

This is a S4 class that has "list" in the data part. This class is created to facilitate validation and extraction of data.

**Objects from the Class**

Objects can be created by calls of the form `new("triangles", ...)`, or use `as(..., "triangles")`, where ... is a "list".

**Slots**

.Data: Object of class "list"

**Extends**

Class "list", from data part. Class "vector", by class "list", distance 2.

**Methods**

**Mse** signature(ModelFit = "GMCLFit", FullTriangles = "triangles"): See [Mse](#)

**Mse** signature(ModelFit = "MCLFit", FullTriangles = "triangles"): See [Mse](#)

[ signature(x = "triangles", i = "missing", j = "numeric", drop = "logical"): Method for primitive function "[" to subset certain columns. If drop=TRUE, rows composed of all "NA"s are removed. Dimensions are not dropped.

[ signature(x = "triangles", i = "missing", j = "numeric", drop = "missing"): Method for primitive function "[" to subset certain columns, where rows composed of all "NA"s are removed. Dimensions are not dropped.

[ signature(x = "triangles", i = "numeric", j = "missing", drop = "logical"): Method for primitive function "[" to subset certain rows. If drop=TRUE, columns composed of all "NA"s are removed. Dimensions are not dropped.

[ signature(x = "triangles", i = "numeric", j = "missing", drop = "missing"): Method for primitive function "[" to subset certain rows, where columns composed of all "NA"s are removed. Dimensions are not dropped.

[ signature(x = "triangles", i = "numeric", j = "numeric", drop = "missing"): Method for primitive function "[" to subset certain rows and columns. Dimensions are not dropped.

[<- signature(x = "triangles", i = "numeric", j = "numeric", value = "list"): Method for primitive function "[<-" to replace one cell in each triangle with values specified in value.

**coerce** signature(from = "list", to = "triangles"): Method to construct a "triangles" object from "list".

**dim** signature(x = "triangles"): Method to get the dimensions. The return value is a vector of length 3, where the first element is the number of triangles, the second is the number of accident years, and the third is the number of development years.

**cbind2** signature(x = "triangles", y="missing"): Method to column bind all triangles using cbind internally.

**rbind2** signature(x = "triangles", y="missing"): Method to row bind all triangles using rbind internally.

**Author(s)**

Wayne Zhang <actuary\_zhang@hotmail.com>

**See Also**

See also [MultiChainLadder](#)

**Examples**

```

data(auto)

# "coerce"
auto <- as(auto,"triangles") # transform "list" to be "triangles"

# method for "["
auto[,4:6,drop=FALSE] # rows of all NA's not dropped
auto[,4:6] # drop rows of all NA's

auto[8:10, ,drop=FALSE] #columns of all NA's not dropped
auto[8:10, ] #columns of all NA's dropped

auto[1:2,1]

# replacement method
auto[1:2,1] <- list(1,2,3)
auto[1,2]

dim(auto)

cbind2(auto[1:2,1])
rbind2(auto[1:2,1])

```

vcov.clark

*Covariance Matrix of Parameter Estimates – Clark's methods***Description**

Function to compute the covariance matrix of the parameter estimates for the ClarkLDF and ClarkCapeCod methods.

**Usage**

```

## S3 method for class 'clark'
vcov(object, ...)

```

**Arguments**

object	object resulting from a run of the ClarkLDF or ClarkCapeCod functions.
...	not used.

**Details**

The covariance matrix of the estimated parameters is estimated by the inverse of the Information matrix (see Clark, p. 53). This function uses the "FI" and "sigma2" values returned by ClarkLDF and by ClarkCapeCod and calculates the matrix  $-\text{sigma2} * \text{FI}^{-1}$ .

**Author(s)**

Daniel Murphy

**References**

Clark, David R., "LDF Curve-Fitting and Stochastic Reserving: A Maximum Likelihood Approach", *Casualty Actuarial Society Forum*, Fall, 2003

**See Also**

[ClarkLDF](#), [ClarkCapeCod](#)

**Examples**

```
x <- GenIns
colnames(x) <- 12*as.numeric(colnames(x))
Y <- ClarkCapeCod(x, Premium=10000000+400000*0:9, maxage=240)
round(vcov(Y),6) ## Compare to matrix on p. 69 of Clark's paper

# The estimates of the loglogistic parameters
Y$THETAG
# The standard errors of the estimated parameters
sqrt(tail(diag(vcov(Y)), 2))

# The parameter risks of the estimated reserves are calculated
# according to the formula on p. 54 of Clark's paper. For example, for
# the 5th accident year, pre- and post-multiply the covariance matrix
# by a matrix consisting of the gradient entries for just that accident year
FVgrad5 <- matrix(Y$FutureValueGradient[, 5], ncol=1)
sqrt(t(FVgrad5 %*% vcov(Y) %*% FVgrad5) ## compares to 314,829 in Clark's paper

# The estimated reserves for accident year 5:
Y$FutureValue[5] ## compares to 2,046,646 in the paper

# Recalculate the parameter risk CV for all accident years in total (10.6% in paper):
sqrt(sum(t(Y$FutureValueGradient) %*% vcov(Y) %*% Y$FutureValueGradient)) /
  Y$Total$FutureValue
```
