

# Package ‘DistatisR’

July 2, 2014

**Type** Package

**Title** DiSTATIS Three Way Metric Multidimensional Scaling

**Version** 1.0

**Date** 2013-07-10

**Author** Derek Beaton [aut, com, ctb], Cherise Chin Fatt [ctb], Herve Abdi [aut, cre]

**Maintainer** Derek Beaton <exposition.software@gmail.com>

## Description

Implement DiSTATIS and CovSTATIS (three-way multidimensional scaling). For the analysis of multiple distance/covariance matrices collected on the same set of observations

**License** GPL-2

**Depends** prettyGraphs (>= 2.0.0), car

**URL** [www.utdallas.edu/~herve](http://www.utdallas.edu/~herve)

**NeedsCompilation** no

**Repository** CRAN

**Date/Publication** 2013-07-11 07:24:31

DistatisR-package	DistatisR: <i>DISTATIS Three Way Metric Multidimensional Scaling</i>
-------------------	--

---

## Description

DistatisR package implements three way multidimensional scaling: DISTATIS and COVSTATIS. Analyses sets of distance (or covariance) matrices collected on the same set of observations

## Details

Package:	DistatisR
Type:	Package
Version:	1.0
Date:	2013-07-03
License:	GPL-2
Depends:	prettyGraphs (>= 2.0.0), car

The example shown here comes from Abdi *et al.* (2007), *distatis* paper on the sorting task.

## Author(s)

## Examples

```
# Here we use the sorting task from Abdi et al, 2007 paper.
# where 10 Assessors sorted 8 beers
```

```
#-----
# 1. Get the data from the 2007 sorting example
#     this is the way they look from Table 1 of
#     Abdi et al. (2007).
#
#           Assessors
#           1 2 3 4 5 6 7 8 9 10
# Beer      Sex f m f f m m m m f m
#-----
#Affligen      1 4 3 4 1 1 2 2 1 3
#Budweiser     4 5 2 5 2 3 1 1 4 3
#Buckler_Blonde 3 1 2 3 2 4 3 1 1 2
#Killian       4 2 3 3 1 1 1 2 1 4
#St. Landelin  1 5 3 5 2 1 1 2 1 3
#Buckler_Highland 2 3 1 1 3 5 4 4 3 1
#Fruit Defendu 1 4 3 4 1 1 2 2 2 4
#EKU28        5 2 4 2 4 2 5 3 4 5
```

```
# 1.1. Create the
#     Name of the Beers
BeerName <- c('Affligen', 'Budweiser', 'Buckler Blonde',
              'Killian', 'St.Landelin', 'Buckler Highland',
```

```

      'Fruit Defendu','EKU28')
# 1.2. Create the name of the Assessors
#      (F are females, M are males)
Juges <- c('F1','M2', 'F3', 'F4', 'M5', 'M6', 'M7', 'M8', 'F9', 'M10')

# 1.3. Get the sorting data
SortData <- c(1, 4, 3, 4, 1, 1, 2, 2, 1, 3,
             4, 5, 2, 5, 2, 3, 1, 1, 4, 3,
             3, 1, 2, 3, 2, 4, 3, 1, 1, 2,
             4, 2, 3, 3, 1, 1, 1, 2, 1, 4,
             1, 5, 3, 5, 2, 1, 1, 2, 1, 3,
             2, 3, 1, 1, 3, 5, 4, 4, 3, 1,
             1, 4, 3, 4, 1, 1, 2, 2, 2, 4,
             5, 2, 4, 2, 4, 2, 5, 3, 4, 5)

# 1.4 Create a data frame
Sort <- matrix(SortData,ncol = 10, byrow= TRUE, dimnames = list(BeerName, Juges))
#      (alternatively we could have read a csv file)
# 1.5 Example of how to read a csv filw
# Sort <- read.table("BeerSortingTask.csv", header=TRUE,
#      sep="," , na.strings="NA", dec=".", row.names=1, strip.white=TRUE)

#-----
# 2. Create the set of distance matrices (one distance matrix per assessor)
#      (uses the function DistanceFromSort)
DistanceCube <- DistanceFromSort(Sort)
#-----
# 3. Call the DISTATIS routine with the cube of distance as parameter
testDistatis <- distatis(DistanceCube)
# The factor scores for the beers are in
# testDistatis$res4$plus$F
# the factor scores for the assessors are in (RV matrice)
# testDistatis$res4$Cmat$G

#-----
# 4. Inferences on the beers obtained via bootstrap
#      here we use two different bootstraps:
#      1. Bootstrap on factors (very fast but could be too liberal
#          when the number of assessors is very large)
#      2. Complete bootstrap obtained by computing sets of compromises
#          and projecting them (could be significantly longer because a lot
#          of computations is required)
#
# 4.1 Get the bootstrap factor scores (with default 1000 iterations)
BootF <- BootFactorScores(testDistatis$res4$plus$PartialF)
#
# 4.2 Get the bootstrap from full bootstrap (default niter = 1000)
F_fullBoot <- BootFromCompromise(DistanceCube,niter=1000)

#-----
# 5. Create the Graphics
# 5.1 an Rv map
rv.graph.out <- GraphDistatisRv(testDistatis$res4$Cmat$G)

```

```

# 5.2 a compromise plot
  compromise.graph.out <- GraphDistatisCompromise(testDistatis$res4Splus$F)
# 5.3 a partial factor score plot
  partial.scores.graph.out <-
    GraphDistatisPartial(testDistatis$res4Splus$F, testDistatis$res4Splus$PartialF)
# 5.4 a bootstrap confidence interval plot
#5.4.1 with ellipses
  boot.graph.out.ell <- GraphDistatisBoot(testDistatis$res4Splus$F, BootF)
#or
# boot.graph.out <- GraphDistatisBoot(testDistatis$res4Splus$F, F_fullBoot)
#5.4.2 with hulls
  boot.graph.out.hull <- GraphDistatisBoot(testDistatis$res4Splus$F, BootF, ellipses=FALSE)
#or
# boot.graph.out <- GraphDistatisBoot(testDistatis$res4Splus$F, F_fullBoot, ellipses=FALSE)
#5.5 all the plots at once
  all.plots.out <-
  GraphDistatisAll(testDistatis$res4Splus$F, testDistatis$res4Splus$PartialF,
  BootF, testDistatis$res4Cmat$G)

```

---

BootFactorScores	<i>BootFactorScores Compute observation Bootstrap replicates of the factor scores from partial factor scores</i>
------------------	--

---

## Description

BootFactorScores Compute Bootstrap replicates of the factor scores of the observations from partial factor scores. The input is obtained from the `distatis` function, the output is a 3-way array of dimensions number of observations by number of factors by number of replicates. The output is typically used to plot confidence intervals (i.e., ellipsoids or convex hulls) or to compute *t*-like statistic called *bootstrap ratios*.

## Usage

```
BootFactorScores(PartialFS, niter = 1000)
```

## Arguments

PartialFS	The partial factor scores (e.g., obtained from <code>distatis</code> )
niter	number of bootstrap iterations (default = 1000)

## Details

To compute a bootstrapped sample a set of  $K$  distance matrices is selected with replacement from the original set of  $K$  distance matrices. The partial factors scores of the selected distance matrices are then averaged to produce the bootstrapped estimate of the factor scores of the observations. This approach is also called *partial bootstrap* by Lebart (2007, see also Chateau & Lebart 1996). It has the advantage of being very fast even for very large data sets Recent work (Cadoret & Husson,

2012), however, suggests that partial bootstrap could lead to optimistic bootstrap estimates when the number of distance matrices is large and that it is preferable to use instead a *total bootstrap* approach (i.e., creating new compromises by resampling and then projecting them on the common solution see function `BootFromCompromise`, and Cadoret & Husson, 2012 see also Abdi *et al.*, 2009 for an example).

### Value

the output is a 3-way array of dimensions "number of observations by number of factors by number of replicates."

### Author(s)

Herve Abdi

### Examples

```
# 1. Load the Sort data set from the SortingBeer example (available from the DistatisR package)
data(SortingBeer)
# Provide an 8 beers by 10 assessors set of results of a sorting task
```

```

#-----
# 2. Create the set of distance matrices (one distance matrix per assessor)
#   (ues the function DistanceFromSort)
DistanceCube <- DistanceFromSort(Sort)

#-----
# 3. Call the DISTATIS routine with the cube of distance as parameter
testDistatis <- distatis(DistanceCube)
# The factor scores for the beers are in
# testDistatis$res4$plus$F
# the partial factor score for the beers for the assessors are in
# testDistatis$res4$plus$PartialF
#
# 4. Get the bootstrapped factor scores (with default 1000 iterations)
BootF <- BootFactorScores(testDistatis$res4$plus$PartialF)

```

---

BootFromCompromise	<i>Compute observation Bootstrap replicates of the factor scores from bootstrapped compromises</i>
--------------------	--

---

## Description

BootFactorScores computes Bootstrap replicates of the factor scores of the observations from bootstrapped compromises. The input is obtained from the same input as the `distatis` function, the output is a 3-way array of dimensions "number of observations by number of factors by number of replicates." The output is typically used to plot confidence intervals (i.e., ellipsoids or convex hulls) or to compute *t*-like statistic called *bootstrap ratios*.

## Usage

```

BootFromCompromise(LeCube2Distance,
                   niter = 1000, Norm = "MFA",
                   Distance = TRUE, RV = TRUE,
                   nfact2keep = 3)

```

## Arguments

LeCube2Distance	The array of distance used to call <code>distatis</code>
niter	The number of bootstrap iterations (default = 1000)
Norm	should be the same as for the original call to <code>distatis</code>
Distance	should be the same as for the original call to <code>distatis</code>
RV	should be the same as for the original call to <code>distatis</code>
nfact2keep	number of factors to keep for the results

### Details

To compute a bootstrapped sample a set of  $K$  distance matrices is selected with replacement from the original set of  $K$  distance matrices. A *distatis* compromise is then computed and projected on the factor space of the original solution to obtain the bootstrapped factor scores. This approach is also called *total bootstrap* by Lebart (2007, see also Chateau and Lebart 1996, see also Abdi *et al.*, 2009 for an example). Compared to the partial bootstrap (see help for `BootFactorScores`) It has the disadvantage of being slow especially for large data sets but recent work (Cadoret & Husson, 2012) suggests that partial bootstrap (i.e., computed from the partial factor scores) could lead to optimistic bootstrap estimates when the number of distance matrices is large and that it is preferable to use instead the *total bootstrap*.

### Value

the output is a 3-way array of dimensions "number of observations by number of factors by number of replicates."

```

---

Chi2Dist

 $\chi^2$  distance between the rows of a rectangular matrix.

---

**Description**

Computes the  $I \times I$  matrix  $\mathbf{D}$  which is the  $\chi^2$  distance matrix between the rows of an  $I \times J$  rectangular matrix  $\mathbf{X}$  (with non-negative elements), and provides the  $I \times 1$   $\mathbf{m}$  vector of mass (where the mass of a row is the sum of the entries of this row divided by the grand total of the matrix). When the distance matrix and the associated vector of masses are used as input to the function `mmds` the results will give the factor scores of the correspondence analysis of the matrix  $\mathbf{X}$ . The function is used by the function `Chi2DistanceFromSort` that computes the  $\chi^2$  distance for the results of a sorting task.

**Usage**

```
Chi2Dist(X)
```

**Arguments**

X                    A rectangle matrix with non-negative elements

**Value**

Sends back a list

\$Distance        the squared  $\chi^2$  distance matrix computed the rows of matrix **X**.  
 masses            the vector of masses of the rows of of matrix **X**.

# 1. Get the Chi2 distance matrix
#    between the rows of Punctuation
Dres <- Chi2Dist(Punctuation)
# check that the mds of the Chi2 distance matrix
# with CA-masses gives the CA factor scores for I
# 2. Use function mmds from DistatisR
#
testmds <- mmds(Dres$Distance,masses=Dres$masses)
# Print the MDS factor scores from mmds
```

```
print('Factor Scores from mds')
print(testmds$FactorScores)
print('It matches CA on X (see Abdi & Williams, 2010. Table 16, p. 449)')
# Et voila!
```

---

Chi2DistanceFromSort    *Creates a 3-dimensional  $\chi^2$  distance array from the results of a sorting task.*

---

## Description

Takes the results from a (plain) sorting task where  $K$  assessors sort  $I$  observations into (mutually exclusive) groups (i.e., one object is in one and only one group). DistanceFromSort creates an  $I \times I \times K$  array of distance in which each of the  $k$  "slices" stores the (sorting) distance matrix of the  $k$ th assessor. In one of these distance matrices, the distance between rows is the  $\chi^2$  distance between rows when the results of the task are coded as 0/1 group coding (i.e., the "complete disjunctive coding" as used in multiple correspondence analysis, see Abdi & Valentin, 2007, for more)

The output of the function DistanceFromSort is used as input for the function [distatis](#).

## Usage

```
Chi2DistanceFromSort(X)
```

## Arguments

X                      gives the results of a sorting task (see example below) as a objects (row) by assessors (columns) matrix.

## Details

The input should have assessors as columns and observations as rows (see example below)

## Value

DistanceFromSort returns a  $I \times I \times K$  array of distances

## Author(s)

Herve Abdi

---

DistAlgo	<i>Four computer algorithms evaluate the similarity of six faces for distatis analysis</i>
----------	--

---

### Description

Provide the data.frame DistAlgo Data set to be used to illustrate the use of the package DistatisR. Four algorithms evaluate the similarity (i.e., distance) between six faces (3 females and 3 males). Each algorithm provides a  $6 \times 6$  distance matrix evaluating the distance between each pair of faces.

### Usage

```
data(DistAlgo)
```

### Format

an  $6 \times 6$  array. Each  $6 \times 6$  matrix is a distance matrix

### Source

DistanceFromSort	<i>Creates a 3-dimensional distance array from the results of a sorting task.</i>
------------------	---

---

### Description

Takes the results from a (plain) sorting task where  $K$  assessors sort  $I$  observations into (mutually exclusive) groups (i.e., one object is in one and only one group). `DistanceFromSort` creates an  $I \times I \times K$  array of distance in which each of the  $k$  "slices" stores the (sorting) distance matrix of the  $k$ th assessor. In one of these distance matrices, a value of 0 at the intersection of a row and a column means that the object represented by the row and the object represented by the column were sorted together (i.e., they are a distance of 0), and a value of 1 means these two objects were put into different groups.

The output of the function `DistanceFromSort` is used as input for the function `distatis`.

### Usage

`DistanceFromSort(X)`

### Arguments

`X` gives the results of a sorting task (see example below) as a objects (row) by assessors (columns) matrix.

### Details

The input should have assessors as columns and observations as rows (see example below)

### Value

`DistanceFromSort` returns a  $I \times I \times K$  array of distances

#-----
# 3. Call the DISTATIS routine with the cube of distance
#   obtained from DistanceFromSort as a parameter for the distatis function
testDistatis <- distatis(DistanceCube)

```

## Description

Implements the DISTATIS method which is a 3-way generalization of metric multidimensional scaling (*a.k.a.* classical MDS or principal coordinate analysis). `distatis` takes a set of  $K$  distance matrices describing a set of  $I$  observations and computes (1) a set of factor scores that describes the similarity structure of the distance matrices (e.g., what distance matrices describe the observations in the same way, what distance matrices differ from each other) (2) a set of factor scores (called the *compromise* factor scores) for the observations that best describes the similarity structure of the observations and (3) partial factor scores that show how each individual distance matrix "sees" the compromise space. `distatis` computes the compromise as an optimum linear combination of the cross-product matrices associated to each distance matrix. `distatis` can also be applied to a set of covariance matrices.

## Usage

```
distatis(LeCube2Distance, Norm = "MFA",
         Distance = TRUE, RV = TRUE,
         nfact2keep = 3,
         compact = FALSE)
```

## Arguments

LeCube2Distance	an "observations $\times$ observations $\times$ distance matrices" array of dimensions $I \times I \times K$ . Each of the $K$ "slices" is a $I \times I$ square distance (or covariance) matrix describing the $I$ observations.
Norm	Type of normalization used for each cross-product matrix derived from the distance (or covariance) matrices. Current options are NONE (do nothing) or MFA (default) that normalizes each matrix so that its first eigenvalue is equal to one.
Distance	if TRUE (default) the matrices are distance matrices, if FALSE they are covariance matrices.
RV	TRUE (default) we use the $R_V$ coefficient to compute the $\alpha$ , FALSE we use the matrix scalar product
nfact2keep	Number of factors to keep for the computation of the factor scores of the observations.
compact	if FALSE we provide detailed output, if TRUE we send back only the $\alpha$ weights (this option is used to make the bootstrap routine <code>BootFromCompromise</code> more efficient).

## Details

DISTATIS is part of the STATIS family. It is often used to analyze the results of sorting tasks.

## Value

`distatis` sends back the results *via* two lists: `res.Cmat` and `res.Splus`. Note that items with a \* are the only ones sent back when using the `compact = TRUE` option

res.Cmat            Results for the between distance matrices analysis.

- res.Cmat\$C The  $I \times I$  **C** matrix of scalar products (or  $R_V$  between distance matrices).
- res.Cmat\$eigenvectors The eigenvectors of the **C** matrix
- res.Cmat\$alpha \* The  $\alpha$  weights
- res.Cmat\$value The eigenvalues of the **C** matrix
- res.CmatG The factor scores for the **C** matrix

res.Splus           Results for the between observation analysis.

- res.Splus\$SCP an  $I \times I \times K$  array. Contains the (normalized if needed) cross product matrices corresponding to the distance matrices.
- res.Splus\$Splus \* The compromise (linear combination of the SCP's')
- res.Splus\$ProjectionMatrix The projection matrix used to compute factor scores and partial factor scores.
- res.Splus\$F The factor scores for the observations.
- res.Splus\$PartialF an  $I \times nf2keep \times K$  array. Contains the partial factors for the distance matrices.

data(DistAlgo)
# DistAlgo is a 6*6*4 Array (face*face*Algorithm)
#-----
# 2. Call the DISTATIS routine with the array of distance (DistAlgo) as parameter
DistatisAlgo <- distatis(DistAlgo)
```

---

GraphDistatisAll	<i>This function combines the functionality of <a href="#">GraphDistatisCompromise</a>, <a href="#">GraphDistatisPartial</a>, <a href="#">GraphDistatisBoot</a>, and <a href="#">GraphDistatisRv</a>.</i>
------------------	---

---

**Description**

This function produces 4 plots: (1) a compromise plot, (2) a partial factor scores plot, (3) a bootstrap confidence intervals plot, and (4) a Rv map.

**Usage**

```
GraphDistatisAll(FS, PartialFS, FBoot, RvFS, axis1 = 1, axis2 = 2, constraints = NULL,
item.colors = NULL, participant.colors = NULL, ZeTitleBase = NULL, nude = FALSE,
Ctr = NULL, RvCtr=NULL, color.by.observations = TRUE, lines = TRUE,
lwd = 3.5, ellipses = TRUE, fill = TRUE, fill.alpha = 0.27, percentage = 0.95)
```

**Arguments**

FS	The factor scores of the observations ( <code>\$res4\$plus\$F</code> from <code>distatis</code> )
PartialFS	The partial factor scores of the observations ( <code>\$res4\$plus\$PartialF</code> from <code>distatis</code> )
FBoot	is the bootstrapped factor scores array (FBoot obtained from <a href="#">BootFactorScores</a> or <a href="#">BootFromCompromise</a> )
RvFS	The factor scores of the distance matrices ( <code>\$res4Cmat\$G</code> from <code>distatis</code> )
axis1	The dimension for the horizontal axis of the plots.
axis2	The dimension for the vertical axis of the plots.
constraints	constraints for the axes
item.colors	A $I$ matrix (with $I = \#$ observations) of color names for the observations. If NULL (default), <code>prettyGraphs</code> chooses.
participant.colors	A $I$ matrix (with $I = \#$ participants) of color names for the observations. If NULL (default), <code>prettyGraphs</code> chooses.

ZeTitleBase	General title for the plots.
nude	When nude is TRUE the labels for the observations are not plotted (useful when editing the graphs for publication).
Ctr	Contributions of each observation. If NULL (default), these are computed from FS
RvCtr	Contributions of each participant. If NULL (default), these are computed from RvFS
color.by.observations	if TRUE (default), the partial factor scores are colored by <code>item.colors</code> . When FALSE, <code>participant.colors</code> are used.
lines	If TRUE (default) then lines are drawn between the partial factor score of an observation and the compromise factor score of the observation.
lwd	Thickness of the line plotting the ellipse or hull.
ellipses	a boolean. When TRUE will plot ellipses (from <code>car</code> package). When FALSE will plot peeled hulls (from <code>prettyGraphs</code> package).
fill	when TRUE, fill in the ellipse with color. Related to ellipses only.
fill.alpha	transparency index when filling in the ellipses. Related to ellipses only.
percentage	A value to determine the percent coverage of the bootstrap partial factor scores to provide ellipse or hull confidence intervals.

**Value**

<code>constraints</code>	A set of plot constraints that are returned.
<code>item.colors</code>	A set of colors for the observations are returned.
<code>participant.colors</code>	A set of colors for the participants are returned.

```

---

GraphDistatisBoot	<i>Plot maps of the factor scores of the observations and their bootstrapped confidence intervals (as confidence ellipsoids or peeled hulls) for a DISTATIS analysis.</i>
-------------------	---

---

## Description

GraphDistatisBoot plots maps of the factor scores of the observations from a [distatis](#) analysis. GraphDistatisBoot gives a map of the factors scores of the observations plus the bootstrapped confidence intervals drawn as "Confidence Ellipsoids" at percentage%.

## Usage

```

GraphDistatisBoot(FS, FBoot, axis1 = 1, axis2 = 2, item.colors = NULL,
ZeTitle = "Distatis-Bootstrap", constraints = NULL, nude = FALSE, Ctr = NULL,
lwd = 3.5, ellipses = TRUE, fill = TRUE, fill.alpha = 0.27, percentage = 0.95)

```

## Arguments

FS	The factor scores of the observations ( <code>\$res4\$plus\$F</code> from <a href="#">distatis</a> )
FBoot	is the bootstrapped factor scores array (FBoot obtained from <a href="#">BootFactorScores</a> or <a href="#">BootFromCompromise</a> )
axis1	The dimension for the horizontal axis of the plots.
axis2	The dimension for the vertical axis of the plots.
item.colors	When present, should be a column matrix (dimensions of observations and 1). Gives the color-names to be used to color the plots. Can be obtained as the output of this or the other graph routine. If NULL, <code>prettyGraphs</code> chooses.
ZeTitle	General title for the plots.
constraints	constraints for the axes
nude	When TRUE do not plot the names of the observations

ctr	Contributions of each observation. If NULL (default), these are computed from FS
lwd	Thickness of the line plotting the ellipse or hull.
ellipses	a boolean. When TRUE will plot ellipses (from car package). When FALSE will plot peeled hulls (from prettyGraphs package).
fill	when TRUE, fill in the ellipse with color. Related to ellipses only.
fill.alpha	transparency index when filling in the ellipses. Related to ellipses only.
percentage	A value to determine the percent coverage of the bootstrap partial factor scores to provide ellipse or hull confidence intervals.

### Details

The ellipses are plotted using the function `dataEllipse()` from the package `car`. The peeled hulls are plotted using the function `peeledHulls()` from the package `prettyGraphs`.

Note that, in the current version, the graphs are plotted as R-plots and are *not* passed back by the function. So the graphs need to be saved "by hand" from the R graphic windows. We plan to improve this in a future version.

### Value

<code>constraints</code>	A set of plot constraints that are returned.
<code>item.colors</code>	A set of colors for the observations are returned.

GraphDistatisCompromise

*Plot maps of the factor scores of the observations for a DISTATIS analysis*

---

**Description**

Plot maps of the factor scores of the observations for a DISTATIS analysis. GraphDistatis gives a map of the factor scores for the observations. The labels of the observations are plotted by defaults but can be omitted (see the `nude=TRUE` option).

**Usage**

```
GraphDistatisCompromise(FS, axis1 = 1, axis2 = 2, constraints = NULL, item.colors = NULL,
ZeTitle = "Distatis-Compromise", nude = FALSE, Ctr = NULL)
```

**Arguments**

FS	The factor scores of the observations ( <code>\$res4Splus\$F</code> from <code>distatis</code> ).
axis1	The dimension for the horizontal axis of the plots.
axis2	The dimension for the vertical axis of the plots.
constraints	constraints for the axes

item.colors	A $I$ matrix (with $I = \#$ observations) of color names for the observations. If NULL (default), prettyGraphs chooses.
ZeTitle	General title for the plots.
nude	When nude is TRUE the labels for the observations are not plotted (useful when editing the graphs for publication).
Ctr	Contributions of each observation. If NULL (default), these are computed from FS

### Details

Note that, in the current version, the graphs are plotted as R-plots and are *not* passed back by the routine. So the graphs need to be saved "by hand" from the R graphic windows. We plan to improve this in a future version.

GraphDistatisCompromise(DistatisAlgo$res4$plus$F)
```

---

GraphDistatisPartial *Plot maps of the factor scores and partial factor scores of the observations for a DISTATIS analysis.*

---

### Description

GraphDistatisPartial plots maps of the factor scores of the observations from a `distatis` analysis. GraphDistatisPartial gives a map of the factors scores of the observations plus partial factor scores, as "seen" by each of the matrices.

### Usage

```
GraphDistatisPartial(FS, PartialFS, axis1 = 1, axis2 = 2, constraints = NULL,
item.colors = NULL, participant.colors = NULL, ZeTitle = "Distatis-Partial",
Ctr=NULL, color.by.observations = TRUE, nude = FALSE, lines = TRUE)
```

### Arguments

FS	The factor scores of the observations ( <code>\$res4\$plus\$F</code> from <code>distatis</code> ).
PartialFS	The partial factor scores of the observations ( <code>\$res4\$plus\$PartialF</code> from <code>distatis</code> )
axis1	The dimension for the horizontal axis of the plots.
axis2	The dimension for the vertical axis of the plots.
constraints	constraints for the axes
item.colors	A $I$ matrix (with $I = \#$ observations) of color names for the observations. If NULL (default), <code>prettyGraphs</code> chooses.
participant.colors	A $I$ matrix (with $I = \#$ participants) of color names for the observations. If NULL (default), <code>prettyGraphs</code> chooses.
ZeTitle	General title for the plots.
Ctr	Contributions of each observation. If NULL (default), these are computed from FS
color.by.observations	if TRUE (default), the partial factor scores are colored by <code>item.colors</code> . When FALSE, <code>participant.colors</code> are used.
nude	When <code>nude</code> is TRUE the labels for the observations are not plotted (useful when editing the graphs for publication).
lines	If TRUE (default) then lines are drawn between the partial factor score of an observation and the compromise factor score of the observation.

### Details

Note that, in the current version, the graphs are plotted as R-plots and are *not* passed back by the routine. So the graphs need to be saved "by hand" from the R graphic windows. We plan to improve this in a future version.

**Value**

constraints      A set of plot constraints that are returned.  
 item.colors      A set of colors for the observations are returned.  
 participant.colors  
                     A set of colors for the participants are returned.

GraphDistatisRv      *Plot maps of the factor scores (from the Rv matrix) of the distance matrices for a DISTATIS analysis*

---

**Description**

Plot maps of the factor scores of the observations for a DISTATIS analysis. The factor scores are obtained from the eigen-decomposition of the between distance matrices cosine matrix (often a matrix of Rv coefficients). Note that the factor scores for the first dimension are always positive. There are used to derive the  $\alpha$  weights for DISTATIS.

**Usage**

```
GraphDistatisRv(RvFS, axis1 = 1, axis2 = 2, ZeTitle = "Distatis-Rv Map",
  participant.colors = NULL, nude = FALSE, RvCtr = NULL)
```

**Arguments**

RvFS	The factor scores of the distance matrices ( $\$res4Cmat\$G$ from <code>distatis</code> ).
axis1	The dimension for the horizontal axis of the plots.
axis2	The dimension for the vertical axis of the plots.
ZeTitle	General title for the plots.
participant.colors	A $I$ matrix (with $I = \#$ participants) of color names for the observations. If NULL (default), <code>prettyGraphs</code> chooses.
nude	When <code>nude</code> is TRUE the labels for the observations are not plotted (useful when editing the graphs for publication).
RvCtr	Contributions of each participant. If NULL (default), these are computed from RvFS

**Details**

Note that, in the current version, the graphs are plotted as R-plots and are *not* passed back by the routine. So the graphs need to be saved "by hand" from the R graphic windows. We plan to improve this in a future version.

**Value**

constraints	A set of plot constraints that are returned.
participant.colors	A set of colors for the participants are returned.

### Examples

```
# 1. Load the DistAlgo data set (available from the DistatisR package)
data(DistAlgo)
# DistAlgo is a 6*6*4 Array (faces*faces*Algorithms)
#-----
# 2. Call the DISTATIS routine with the array of distance (DistAlgo) as parameter
DistatisAlgo <- distatis(DistAlgo)
# 3. Plot the compromise map with the labels for the first 2 dimensions
# DistatisAlgo$res4Cmat$G are the factors scores
# for the 4 distance matrices (i.e., algorithms)
  GraphDistatisRv(DistatisAlgo$res4Cmat$G,ZeTitle='Rv Mat')
# Et voila!
```

---

mmds

*mmds Metric (classical) Multidimensional Scaling (a.k.a Principal Coordinate Analysis) of a (Euclidean) Distance Matrix*

---

### Description

Perform an MMDS of a (Euclidean) distance matrix measured between a set of weighted objects.

MMDS Give factor scores that make it possible to draw a map of the objects such that the distances between objects on the map best approximate the original distances between objects.

**Method:** Transform the distance matrix into a (double centered) covariance matrix which is then analyze via its eigen-decomposition. The factor score of each dimension are scaled such that their variance (i.e., the sum of their weighted squared factor scores) is equal to the eigen-value of the corresponding dimension. Note that if the masses vector is absent, equal masses (i.e. 1 divided by number of objects) are used.

**Usage**

```
mmds(DistanceMatrix, masses=NULL)
```

**Arguments**

`DistanceMatrix` . A squared (assumed to be Euclidean) distance matrix

`masses` A vector of masses (i.e., non negative numbers with a sum of 1) of same dimensionality as number of rows of `DistanceMatrix`.

**Value**

Sends back a list

`LeF` factor scores for the objects.

`eigenvalues` the eigenvalues for the factor scores (ie.a variance).

`tau` the percentage of explained variance of each dimension.

`Contributions` give the proportion of explained variance by an object for a dimension.

print.Cmat

*Print C matrix results*

---

### Description

Print C matrix results.

### Usage

```
## S3 method for class 'Cmat'
print(x,...)
```

### Arguments

x                    a list that contains items to make into the Cmat class.  
...                   inherited/passed arguments for S3 print method(s).

### Author(s)

Derek Beaton

print.DistatisR      *Print DistatisR results*

---

**Description**

Print DistatisR results.

**Usage**

```
## S3 method for class 'DistatisR'  
print(x,...)
```

**Arguments**

x                    a list that contains items to make into the DistatisR class.  
...                  inherited/passed arguments for S3 print method(s).

SortingBeer

*Ten Assessors sorted eight beers for distatis analysis*

---

**Description**

Provide the data.frame Sort: Data set to be used to illustrate the use of the package DistatisR. Ten assessors sorted eight beers. These data come from the Abdi et al.' (2007) paper in *Food Quality and Preference*. Each column represents the results of the sorting task for one assessor. Beers with the same number were sorted together.

**Usage**

```
data(SortingBeer)
```

**Format**

a data frame file containing 10 columns, 8 rows plus the names of the rows and the columns.

**Source**
