bayesLife-package	<i>Bayesian Projection of the Life Expectancy</i>
-------------------	---

Description

Collection of functions for making probabilistic projections of the life expectancy for all countries of the world, using a Bayesian hierarchical model and the United Nations demographic time series.

Details

Package: bayesLife
 Type: Package
 Version: 2.1-1
 Date: 2014-6-2
 License: GPL (>= 2)
 URL: <http://bayespop.csss.washington.edu>

The projection follows a method developed by Chunn et al. It uses historical data provided by the United Nations (included in the package) to simulate a posterior distribution of the life expectancy for all countries in the world simultaneously.

The package is implemented in a similar way as the **bayesTFR** package and thus, many functions have their equivalents in **bayesTFR**. The main functions of the **bayesLife** package are:

- `run.e0.mcmc`: Evokes running a Markov Chain Monte Carlo (MCMC) simulation for one or more chains, possibly in parallel. It results in a posterior sample of the mcmc parameters. Existing simulation runs can be resumed using `continue.e0.mcmc`.
- `e0.predict`: Using the posterior parameter samples it derives posterior trajectories of the life expectancy for all countries.
- `linke0.jmale.predict`: Given existing outputs of `e0.predict` for female life expectancy, this function estimates and predicts a joint male life expectancy as described in Lalic 2011.

A number of functions analyzing results are included in the package:

- `e0.trajectories.plot`: Shows the posterior trajectories for a given country, including their median and given probability intervals.
- `e0.trajectories.table`: Shows the posterior trajectories for a given country in a tabular form.
- `e0.map`: Shows a world map of life expectancy for a given projection period.
- `e0.DLcurve.plot`: Shows the posterior curves of the double logistic function used in the simulation, including their median and given probability intervals.
- `e0.partraces.plot` and `e0.partraces.cs.plot`: Plot the MCMC traces of country-independent parameters and country-specific parameters, respectively.
- `e0.pardensity.plot` and `e0.pardensity.cs.plot`: Plot the posterior density of the MCMCs for country-independent parameters and country-specific parameters, respectively.
- `summary.bayesLife.mcmc.set`: Summary function for the MCMC results.
- `summary.bayesLife.prediction`: Summary function for the prediction results.

For MCMC diagnostics, function `e0.coda.list.mcmc` creates an object of type “mcmc.list” that can be used with the **coda** package. Furthermore, function `e0.diagnose` analyzes the MCMCs using the Raftery diagnostics implemented in the **coda** package and gives information about parameters that did not converge. Function `e0.dl.coverage` computes a goodness of fit of the double logistic function.

Existing simulation results can be accessed using the `get.e0.mcmc` function. An existing prediction can be accessed via `get.e0.prediction`.

Historical data are taken from one of the packages **wpp2008**, **wpp2010** or **wpp2012**, depending on users settings.

Note

There is a directory `ex-data` shipped with the package which contains results from an example simulation, containing two chains with 60 iterations each, thinned by two. The Example section below shows how these results were created. These data are used in Example sections throughout the manual. The user can either reproduce the data in her/his local directory, or use the ones from the package.

A ‘real’ (converged) simulation including predictions can be downloaded from <http://bayespop.csss.washington.edu>.

bayesLife.mcmc

MCMC Simulation Object

Description

MCMC simulation object `bayesLife.mcmc` containing information about one MCMC chain. A set of such objects belonging to the same simulation together with a `bayesLife.mcmc.meta` object constitute a `bayesLife.mcmc.set` object.

Details

An object `bayesLife.mcmc` points to a place on disk (element `output.dir`) where MCMC results from all iterations are stored. They can be retrieved to the memory using `get.e0.mcmc(...)`.

The object is in standard cases not to be manipulated by itself, but rather as part of a `bayesLife.mcmc.set` object.

Value

A bayesLife.mcmc object contains parameters of the Bayesian hierarchical model, more specifically, their initial values (all names with the suffix .ini) and values from the last iteration. These are:

Triangle/Triangle.ini, lambda/lambda.ini - world parameters, containing four values each. They correspond to model parameters $\Delta_1, \dots, \Delta_4$ and $\lambda_1, \dots, \lambda_4$, respectively.

k/k.ini, z/z.ini, omega/omega.ini, lambda.k/lambda.k.ini, lambda.z/lambda.z.ini - world parameters, containing one value each. They correspond to model parameters k, z, ω, λ_k , and λ_z , respectively.

Triangle.c - country-specific parameter $\Delta_1^c, \dots, \Delta_4^c$ with four values for each country, i.e. an $4 \times C$ matrix where C is the number of countries.

k.c, z.c - country-specific parameters k^c and z^c (1d arrays of length C).

Furthermore, the object contains components:

iter	Total number of iterations the simulation was started with.
finished.iter	Number of iterations that were finished. Results from the last finished iteration are stored in the parameters above.
length	Length of the MCMC stored on disk. It differs from finished.iter only if thin is larger than one.
thin	Thinning interval used when simulating the MCMCs.
id	Identifier of this chain.
output.dir	Subdirectory (relative to output.dir in the bayesLife.mcmc.meta object) where results of this chain are stored.
traces	This is a placeholder for keeping whole parameter traces in the memory. If the processing operates in a low memory mode, it will be 0. It can be filled in using the function <code>get.e0.mcmc(..., low.memory=FALSE)</code> . In such a case, traces is a $I \times J$ array where I is the MCMC length and J is the number of parameters.
traces.burnin	Burnin used to retrieve the traces, i.e. how many stored iterations are missing from the beginning in the traces array comparing to the 'raw' traces on the disk.
rng.state	State of the random number generator at the end of the last finished iteration.
meta	Object of class bayesLife.mcmc.meta used for simulation of this chain.

Examples

```
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
# loads traces from one chain
m <- get.e0.mcmc(sim.dir, low.memory=FALSE, burnin=35, chain.ids=1)
```

```
# should have 13 rows, since 60 iterations in total minus 35 burnin with thin=2
dim(e0.mcmc(m, 1)$traces)
summary(m)
```

bayesLife.mcmc.meta *MCMC Simulation Meta Object*

Description

Simulation meta object `bayesLife.mcmc.meta` used by all chains of the same MCMC simulation. It contains information that is common to all chains. It is a part of a `bayesLife.mcmc.set` object.

Details

The object is in standard cases not to be manipulated by itself, but rather as part of a `bayesLife.mcmc.set` object.

Value

A `bayesLife.mcmc.meta` object contains components `sex`, `nr.chains`, `start.year`, `present.year`, `wpp.year`, `buffer.size`, `my.e0.file`, `a`, `delta`, `tau`, `Triangle.ini`, `k.ini`, `z.ini`, `omega.ini`, `lambda.ini`, `lambda.k.ini`, `lambda.z.ini`, `Triangle.ini.low`, `Triangle.ini.up`, `k.ini.low`, `k.ini.up`, `z.ini.low`, `z.ini.up`, `lambda.ini.low`, `lambda.ini.up`, `lambda.k.ini.low`, `lambda.k.ini.up`, `lambda.z.ini.low`, `lambda.z.ini.up`, `omega.ini.low`, `omega.ini.up`, `Triangle.c.ini.norm`, `k.c.ini.norm`, `z.c.ini.norm`, `Triangle.c.prior.low`, `Triangle.c.prior.up`, `k.c.prior.low`, `k.c.prior.up`, `z.c.prior.low`, `z.c.prior.up`, `Triangle.c.width`, `k.c.width`, `z.c.width`, `nu`, `dl.p1`, `dl.p2`, `sumTriangle.lim`, `auto.conf`. Their meaning and value are the same as the input arguments to the `run.e0.mcmc` function. Furthermore, it contains components:

<code>e0.matrix.all</code>	A $q \times n$ matrix with the United Nations life expectancy estimates. q is number of years, n is number of countries (see <code>nr.countries</code> below). The first n_e columns correspond to countries included in the MCMC estimation (see <code>nr.countries.estimation</code> below), where $n_e \leq n$. The order of the countries corresponds to the order of countries in the element regions, see below.
<code>e0.matrix</code>	Like <code>e0.matrix.all</code> , but it has NA values for years where no historical data is available.
<code>d.ct</code>	A difference <code>e0</code> matrix of size $(q - 1) \times n$. Each element $x_{t,i}$ is a difference $y_{t+1,i} - y_{t,i}$ where y denotes elements of <code>e0.matrix</code> .
<code>loessSD</code>	The loess matrix of <code>d.ct</code> .
<code>nr.countries</code>	Number of countries included in the <code>e0</code> matrices.
<code>nr.countries.estimation</code>	Number of countries included in the MCMC estimation. It must be smaller or equal to <code>nr.countries</code> .
<code>Tc.index</code>	A list with one element per country. For each country, it contains the index within <code>e0.matrix</code> where the observed historical data are not NA, i.e. it points to the data used in the estimation.

regions	List of arrays of length nr.countries. These are: name - Region name for each country. code - Region code for each country. area_name - Area name for each country. area_code - Area code for each country. country_name - Array of country names. country_code - Array of country codes. Any country indices in the bayesLife.mcmc.meta object are derived from this component.
output.dir	Directory for storing simulation output.
suppl.data	If supplemental data were used in the simulation (i.e. start year was set prior to 1950), this is a list containing information about the additional data. It has the following components of the same form as described above, but related only to the additional data: e0.matrix, regions, Tc.index, nr.countries, d.ct, loessSD. In addition, it has the vectors index.from.all.countries - a vector of size nr.countries (all countries) where each element is an index to the supplemental data, i.e. a match from regions\$country_code to suppl.data\$regions\$country_code. index.to.all.countries - a vector of size suppl.data\$nr.countries (additional countries) where each element is an index to all data, i.e. a match from suppl.data\$regions\$country_code to regions\$country_code.

```

convert.e0.trajectories

Converting Trajectories of Life Expectancy into ACSII Files

Description

Converts trajectories of the life expectancy stored in a binary format into two CSV files of a UN-specific format.

Usage

```
convert.e0.trajectories(dir = file.path(getwd(), "bayesLife.output"),  
  n = 1000, output.dir = NULL, verbose = FALSE)
```

Arguments

dir	Directory containing the prediction object. It should correspond to the output.dir argument of the e0.predict function.
n	Number of trajectories to be stored. It can be either a single number or the word “all” in which case all available trajectories are converted.
output.dir	Directory in which the resulting files will be stored. If NULL the same directory is used as for the prediction.
verbose	Logical switching log messages on and off.

Details

The function creates two files. One is called “ascii_trajectories.csv”, it is a comma-separated table with the following columns:

- “LocID”: country code
- “Period”: prediction interval, e.g. 2015-2020
- “Year”: middle year of the prediction interval
- “Trajectory”: identifier of the trajectory
- “e0”: life expectancy

The second file is called “ascii_trajectories_wide.csv”, it is also a comma-separated table and it contains the same information as above but in a ‘transposed’ format. I.e. the data for one country are ordered in columns, thus, there is one column per country. The country columns are ordered alphabetically.

If n is smaller than the total number of trajectories, the trajectories are selected using equal spacing.

Note

This function is automatically called from the [e0.predict](#) function, therefore in standard cases it will not be needed to call it directly. However, it can be useful for example, if different number of trajectories are to be converted, without having to re-run the prediction.

Examples

```
## Not run:
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
pred.dir <- file.path(getwd(), "exampleLEpred")

# stores 10 trajectories out of 26 (2x(60-35)/2 + 1) into
# exampleLEpred/predictions/ascii_trajectories.csv
e0.predict(sim.dir=sim.dir, output.dir=pred.dir,
           burnin=35, save.as.ascii=10, verbose=TRUE)

# stores all 26 trajectories into the current directory
convert.e0.trajectories(dir=pred.dir, n="all", output.dir=".", verbose=TRUE)

# Note: If the output.dir argument in e0.predict is omitted,
# call convert.e0.trajectories with dir=sim.dir

## End(Not run)
```

e0.coda.list.mcmc *Conversion to coda's Objects*

Description

The functions convert MCMC traces (simulated using [run.e0.mcmc](#)) into objects that can be used with the **coda** package.

Usage

```
e0.coda.list.mcmc(mcmc.list = NULL, country = NULL, chain.ids = NULL,
                 sim.dir = file.path(getwd(), "bayesLife.output"),
                 par.names = e0.parameter.names(),
                 par.names.cs = e0.parameter.names.cs(), low.memory = FALSE, ...)

## S3 method for class 'bayesLife.mcmc'
coda.mcmc(mcmc, country = NULL, par.names = e0.parameter.names(),
          par.names.cs = e0.parameter.names.cs(), ...)
```

Arguments

mcmc.list	List of bayesLife.mcmc objects, or an object of class bayesLife.mcmc.set or bayesLife.prediction . If it is NULL, the MCMCs are loaded from sim.dir. Either mcmc.list or sim.dir must be given.
mcmc	Object of class bayesLife.mcmc .
country	Country name or code. It is used in connection with the par.names.cs argument (see below).
chain.ids	Vector of chain identifiers. By default, all chains available in the mcmc.list object are included.

<code>sim.dir</code>	Directory with the MCMC simulation results. Only used if <code>mcmc.list</code> is NULL.
<code>par.names</code>	Names of country-independent parameters to be included.
<code>par.names.cs</code>	Names of country-specific parameters to be included. The argument <code>country</code> is used to filter out traces that correspond to a specific country. If <code>country</code> is not given, for each parameter, traces for all countries are included.
<code>low.memory</code>	Logical indicating if the function should run in a memory-efficient mode.
<code>...</code>	Additional arguments passed to the coda 's <code>mcmc</code> function, such as <code>burnin</code> and <code>thin</code> .

Value

The function `e0.coda.list.mcmc` returns an object of class "mcmc.list". The function `coda.mcmc` returns an object of class "mcmc", both defined in the **coda** package.

Author(s)

Hana Sevcikova

See Also

[e0.partraces.plot](#) for plotting the MCMC traces and [summary.bayesLife.mcmc.set](#).

Examples

```
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
coda.list <- e0.coda.list.mcmc(sim.dir=sim.dir, country="France", burnin=30)
summary(coda.list)
```

<code>e0.diagnose</code>	<i>Convergence Diagnostics for Markov Chain Monte Carlo of Life Expectancy</i>
--------------------------	--

Description

Function `e0.diagnose` runs convergence diagnostics of existing MCMCs, using the `raftery.diag` function from the **coda** package.

Usage

```
e0.diagnose(sim.dir, thin=225, burnin = 10000, express = FALSE,
            country.sampling.prop = NULL, keep.thin.mcmc=FALSE, verbose = TRUE)
```

Arguments

sim.dir	Directory with the MCMC simulation results.
thin	Thinning interval.
burnin	Number of iterations to be discarded from the beginning of the parameter traces.
express	Logical. If TRUE, the convergence diagnostics is run only on the country-independent parameters. If FALSE, the country-specific parameters are included in the diagnostics. The number of countries can be controlled by <code>country.sampling.prop</code> .
country.sampling.prop	Proportion of countries that are included in the diagnostics. If it is NULL and <code>express=FALSE</code> , all countries are included. Setting here a number between 0 and 1, one can limit the number of countries which are then randomly sampled. Note that for long MCMCs, this argument may significantly influence the runtime of this function.
keep.thin.mcmc	Logical. If TRUE the thinned traces used for computing the diagnostics are stored on disk (see <code>create.thinned.e0.mcmc</code>).
verbose	Logical switching log messages on and off.

Details

The function invokes the `e0.raftery.diag` function separately for country-independent parameters and for country-specific parameters. It results in two possible states: red, i.e. it did not converge, and green, i.e. it converged. The resulting object is stored in `'{sim.dir}/diagnostics/bayesLife.convergence_{thin}_{burnin}.rda'` and can be accessed using the function `get.e0.convergence`.

Function `has.mcmc.converged` from the **bayesTFR** package can be used to check if the existing diagnostics converged.

Value

`e0.diagnose` returns an object of class `bayesLife.convergence` with components:

result	Table containing all not-converged parameters. Its columns include 'Total iterations needed' and 'Remaining iterations'.
lresult.country.independent	Number of rows in <code>result</code> that correspond to country-independent parameters. These rows are grouped at the beginning of the table.
country.independent	Result of <code>e0.raftery.diag</code> processed on country-independent parameters.
country.specific	Result of <code>e0.raftery.diag</code> processed on country-specific parameters.
iter.needed	Number of additional iterations suggested in order to achieve convergence.
iter.total	Total number of iterations of the original unthinned set of chains.
use.nr.traj	Suggestion for number of trajectories in generating predictions.
burnin	Burnin used.
thin	Thinning interval used.

status	Vector of character strings containing the result status. Possible values: 'green', 'red'.
mcmc.set	Object of class <code>bayesLife.mcmc.set</code> that corresponds to the original set of MCMCs on which the diagnostics was run.
thin.mcmc	If <code>keep.thin.mcmc</code> is TRUE, it is an object of class <code>bayesLife.mcmc.set</code> that corresponds to the thinned mcmc set on which the diagnostics was run, otherwise NULL.
express	Value of the input argument <code>express</code> .
nr.countries	Vector with elements used - number of countries used in this diagnostics, and total - number of countries that this <code>mcmc.set</code> object was estimated on.

e0.dl.coverage

Goodness of Fit of the Double Logistic Function

Description

The function computes coverage, i.e. the ratio of observed data fitted within the given probability intervals of the predictive posterior distribution of the double logistic function, as well as the root mean square error of the simulation.

Usage

```
e0.dl.coverage(sim.dir, pi = c(80, 90, 95), burnin = 10000, verbose = TRUE)
```

Arguments

sim.dir	Directory with the MCMC simulation results. If a prediction and its corresponding thinned mcmcs are available in the simulation directory, those are taken for assessing the goodness of fit.
pi	Probability interval. It can be a single number or an array.
burnin	Burnin. Only relevant if <code>sim.dir</code> does not contain thinned chains.
verbose	Logical switching log messages on and off.

Value

List with the same components as [tfr.dl.coverage](#).

Note

To see the fit visually per country, use `e0.DLcurve.plot(..., predictive.distr=TRUE,...)`.

Author(s)

Hana Sevcikova

See Also

[e0.DLcurve.plot](#)

Examples

```
## Not run:
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
e0 <- get.e0.mcmc(sim.dir)
# Note that this simulation is a toy example and thus has not converged.
gof <- e0.dl.coverage(sim.dir)
gof$country.coverage
e0.DLcurve.plot(e0, country=608, predictive.distr=TRUE, pi=c(80, 90, 95))

## End(Not run)
```

e0.DLcurve.plot	<i>Plotting Posterior Distribution of the Double Logistic Function of Life Expectancy</i>
-----------------	---

Description

The functions plot the posterior distribution of the double logistic function used in the simulation, including their median and given probability intervals.

Usage

```
e0.DLcurve.plot(mcmc.list, country, burnin = NULL, pi = 80,
  e0.lim = NULL, nr.curves = 20, predictive.distr = FALSE, ylim = NULL,
  xlab = "e(0)", ylab = "5-year gains", main = NULL, ...)

e0.DLcurve.plot.all(mcmc.list = NULL, sim.dir = NULL,
  output.dir = file.path(getwd(), "DLcurves"),
  output.type = "png", burnin = NULL, verbose = FALSE, ...)
```

Arguments

mcmc.list	List of <code>bayesLife.mcmc</code> objects, an object of class <code>bayesLife.mcmc.set</code> or of class <code>bayesLife.prediction</code> . In case of <code>e0.DLcurve.plot.all</code> if it is NULL, it is loaded from <code>sim.dir</code> .
country	Name or numerical code of a country.

burnin	Number of iterations to be discarded from the beginning of parameter traces.
pi	Probability interval. It can be a single number or an array.
e0.lim	It can be a tuple of the minimum and maximum life expectancy to be shown in the plot. If NULL, it takes the minimum of observed data and 40, and the maximum of observed data and 90.
nr.curves	Number of curves to be plotted. If NULL, all curves are plotted.
predictive.distr	Logical. If TRUE, an error term is added to each trajectory.
ylim, xlab, ylab, main	Graphical parameters passed to the plot function.
...	Additional graphical parameters. In addition, any arguments from e0.DLcurve.plot except country can be passed to e0.DLcurve.plot.all.
sim.dir	Directory with the simulation results. Only relevant, if mcmc.list is NULL.
output.dir	Directory into which resulting graphs are stored.
output.type	Type of the resulting files. It can be "png", "pdf", "jpeg", "bmp", "tiff", or "postscript".
verbose	Logical switching log messages on and off.

Details

e0.DLcurve.plot plots double logistic curves for the given country. e0.DLcurve.plot.all creates such plots for all countries and stores them in output.dir. Parameters passed to the double logistic function are either thinned traces created by the [e0.predict](#) function (if mcmc.list is an object of class [bayesLife.prediction](#)), or they are selected by equal spacing from the MCMC traces. In the former case, burnin is set automatically; in the latter case, burnin defaults to 0. If nr.curves is smaller than 2000, the median and probability intervals are computed on a sample of 2000 equally spaced data points, otherwise on all plotted curves.

Author(s)

Hana Sevcikova

Examples

```
## Not run:
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
mcmc.set <- get.e0.mcmc(sim.dir=sim.dir)
e0.DLcurve.plot(country="Japan", mcmc.set, burnin=40)

## End(Not run)
```

e0.gap.plot

Posterior Distribution of Gaps in Female and Male Life Expectancy

Description

The functions plot the posterior distribution of the gaps between female and male life expectancy, modeled and predicted using a model described in Lalic (2011). This can be done for one country (`e0.gap.plot`) or for all countries (`e0.gap.plot.all`).

Usage

```
e0.gap.plot(e0.pred, country, e0.pred2 = NULL, pi = c(80, 95),
  nr.traj = 0, xlim = NULL, ylim = NULL, type = "b",
  xlab = "Year", ylab = "Gap in life expectancy", main = NULL,
  show.legend = TRUE, ...)
```

```
e0.gap.plot.all(e0.pred, output.dir = file.path(getwd(), "e0gaps"),
  output.type = "png", verbose = FALSE, ...)
```

Arguments

<code>e0.pred</code>	Object of class <code>bayesLife.prediction</code> containing female projections. If <code>e0.pred2</code> is not given, then this object must contain the 'joint.male' component, generated using the <code>e0.jmale.predict</code> function.
<code>country</code>	Name or numerical code of a country.
<code>e0.pred2</code>	Object of class <code>bayesLife.prediction</code> containing male projections. By default the male projections is taken from the joint female-male projections in <code>e0.pred</code> , see above.
<code>pi</code>	Probability interval. It can be a single number or an array.
<code>nr.traj</code>	Number of trajectories to be plotted.
<code>xlim, ylim, type, xlab, ylab, main</code>	Graphical parameters passed to the plot function.
<code>show.legend</code>	Logical controlling whether the legend should be drawn.
<code>output.dir</code>	Directory into which resulting graphs are stored.
<code>output.type</code>	Type of the resulting files. It can be "png", "pdf", "jpeg", "bmp", "tiff", or "postscript".
<code>verbose</code>	Logical switching log messages on and off.
<code>...</code>	Additional graphical parameters. In addition, for <code>e0.gap.plot.all</code> , <code>...</code> contains any of the arguments of <code>e0.gap.plot</code> .

<code>e0.jmale.estimate</code>	<i>Estimation of the Joint Female-Male Model</i>
--------------------------------	--

Description

The function estimates the joint female-male model of life expectancy, as described in Raftery et al. (2012) and Lalic (2011). It consist of two equations with t-distributed errors, see Details below.

Usage

```
e0.jmale.estimate(mcmc.set, countries.index = NULL,
  estDof.eq1 = TRUE, start.eq1 = list(dof = 2), max.e0.eq1 = 83,
  estDof.eq2 = TRUE, start.eq2 = list(dof = 2),
  constant.gap.eq2 = TRUE, my.e0.file = NULL, verbose = FALSE)
```

Arguments

<code>mcmc.set</code>	Object of class bayesLife.mcmc.set containing estimation results of female life expectancy.
<code>countries.index</code>	Index of countries (within the <code>mcmc.set</code> object) to be included in the estimation. By default, all countries included in the estimation of <code>mcmc.set</code> are used.
<code>estDof.eq1</code> , <code>estDof.eq2</code>	Logical, controlling whether the degrees of freedom of the first and second equation, respectively, should be estimated. If it is FALSE the degrees of freedom are set using the arguments <code>start.eq1</code> and <code>start.eq2</code> , respectively.
<code>start.eq1</code> , <code>start.eq2</code>	Argument <code>start</code> of the <code>tlm</code> function of the hett package, which is applied to the first and second equation of the model, respectively. It is a list of possibly four named components, ("beta", "lambda", "dof", "omega"), for the location, scale, degrees of freedom parameters and random scale effects respectively. If <code>estDof.eq1</code> (<code>estDof.eq2</code>) is FALSE, the "dof" component must be given.
<code>max.e0.eq1</code>	Maximum female life expectancy of records included in the estimation of the first equation (parameter M in Details below).

constant.gap.eq2	Logical. If TRUE the coefficient of the second equation (γ_1) is set to one and the standard deviation is estimated under the assumption of normal distribution.
my.e0.file	File name containing user-specified male time series for one or more countries. The function replaces the corresponding country data from the WPP dataset by values in this file. Only columns are replaced that match column names of the WPP dataset.
verbose	Logical switching log messages on and off. If TRUE summary results from the <code>t1m</code> function of both equations are shown.

Details

The joint female-male life expectancy model is a model for estimating gaps G between female and male life expectancy. It consists of two parts, see Equation (1) in Raftery et al. (2012):

1. If $l_{c,t} \leq M$, then

$$G_{c,t} = \beta_0 + \beta_1 l_{c,1953} + \beta_2 G_{c,t-1} + \beta_3 l_{c,t} + \beta_4 (l_{c,t} - 75)_+ + \epsilon_{c,t}$$

where $\epsilon_{c,t}$ is iid $t(\mu = 0, \sigma_1^2, \nu_1)$.

2. If $l_{c,t} > M$, then

$$G_{c,t} = \gamma_1 G_{c,t-1} + \epsilon_{c,t}$$

where $\epsilon_{c,t}$ is iid $t(\mu = 0, \sigma_2^2, \nu_2)$.

Here, t is the time and c is the country index. $G_{c,t}$ is the gap for country c at time t and $l_{c,t}$ is the female life expectancy for country c at time t . M can be set in the `max.e0.eq1` argument.

Using the `t1m` function of the `hett` package, the function estimates the coefficients β_i ($i = 1, \dots, 4$) and γ_1 , as well as parameters σ_j ($j = 1, 2$) and optionally the degrees of freedom ν_j ($j = 1, 2$). If `constant.gap.eq2` is TRUE, γ_1 is set to 1 and $\epsilon_{c,t}$ is iid $N(\mu = 0, \sigma_2^2)$.

The `mcmc.set` object should be a `bayesLife.mcmc.set` object obtained from a simulation of a female life expectancy. Note that since only the observed data and no MCMC results are used in this estimation, the `mcmc.set` object can be obtained from a toy simulation such as in the example below. The function extracts observed data from this object and treats them as $l_{c,t}$. For the male historical time series, the function takes the male WPP dataset from the same `wpp` package as the female data (`e0M`) and possibly partly replaces it by any user-specified data given in `my.e0.file`.

Value

List with the components, `eq1` and `eq2`, each containing estimation results from the first and second equation, respectively. These are:

<code>coefficients</code>	Estimated coefficients β_i .
<code>sigma</code>	Parameter σ_j .
<code>dof</code>	Degrees of freedom ν_j . If <code>estDof.eq1</code> (<code>estDof.eq2</code>) is TRUE this parameter is estimated, otherwise it is set to the value of <code>start.eq1\$dof</code> (<code>start.eq2\$dof</code>).

e0.jmale.predict

Prediction of the Joint Female-Male Model

Description

Prediction of the joint female-male model of life expectancy, as described in Raftery et al. (2012) and Lalic (2011).

Usage

```
e0.jmale.predict(e0.pred, estimates = NULL, gap.lim = c(0, 18),
  max.e0.eq1.pred = 83, my.e0.file = NULL,
  save.as.ascii = 1000, verbose = TRUE, ...)
```

Arguments

e0.pred	Object of class bayesLife.prediction containing female projections of life expectancy.
estimates	List of the same structure as returned by e0.jmale.estimate , containing the model estimation results. If it is not given, the e0.jmale.estimate function is invoked.
gap.lim	Vector of length two giving the minimum and maximum bounds for the female-male life expectancy gaps.
max.e0.eq1.pred	Maximum female life expectancy for male projections handled by the first equation (parameter M in Equation (1) in Raftery et al. (2012)).

my.e0.file	File name containing user-specified male time series for one or more countries. The function replaces the corresponding country data from the WPP dataset by values in this file. Only columns are replaced that match column names of the WPP dataset.
save.as.ascii	Either a number determining how many trajectories should be converted into an ASCII file, or “all” in which case all trajectories are converted. It should be set to 0, if no conversion is desired.
verbose	Logical switching log messages on and off.
...	Further arguments passed to <code>e0.jmale.estimate</code> .

Details

If no estimates are given, the function invokes an estimation by calling `e0.jmale.estimate`. Using those estimates, the male life expectancy is projected forward in time (as a function of a female-male gap), using the female predictions from `e0.pred`. The initial male data point is extracted from the male WPP dataset (`e0M`) and possibly partly replaced by any user-specified data given in `my.e0.file`.

The resulting trajectory files are stored in a subdirectory of the female prediction directory, called ‘joint_male’. Furthermore, an object of class `bayesLife.prediction` is created and added to `e0.pred` as a component called `joint.male`.

The predicted gaps can be viewed using the `e0.gap.plot` function.

Value

Updated `e0.pred` object where a new component was added, called `joint.male`. It is also an object of class `bayesLife.prediction` and it contains results from this prediction.

e0.joint.plot

Joint Posterior Distribution of Female and Male Life Expectancy

Description

The functions plot the joint posterior distribution of female and male life expectancy, modeled and predicted using the joint model described in Lalic (2011). This can be done for one country (`e0.joint.plot`) or for all countries (`e0.joint.plot.all`).

Usage

```

e0.joint.plot(e0.pred, country, pi = 95, years, nr.points = 500,
  obs.pch = 17, obs.cex=1, xlim = NULL,
  ylim = NULL, xlab = "Female life expectancy", ylab = "Male life expectancy",
  main = NULL, col = NULL, show.legend = TRUE, add = FALSE, ...)

e0.joint.plot.all(e0.pred, output.dir = file.path(getwd(), "e0joint"),
  output.type = "png", verbose = FALSE, ...)

```

Arguments

<code>e0.pred</code>	Object of class <code>bayesLife.prediction</code> containing female projections.
<code>country</code>	Name or numerical code of a country.
<code>pi</code>	Probability interval. It can be a single number or an array.
<code>years</code>	Array of future years for which to plot the distribution.
<code>nr.points</code>	Number of points shown in the plot for each year.
<code>obs.pch, obs.cex</code>	Graphical parameters used for displaying observed data or data without variation.

xlim, ylim, xlab, ylab, main	Graphical parameters passed to the <code>plot</code> function.
col	Array of colors, one for each year.
show.legend	Logical controlling whether the legend should be drawn.
add	Logical controlling whether the distribution should be plotted into a new graphic device (FALSE) or into an existing device (TRUE).
output.dir	Directory into which resulting graphs are stored.
output.type	Type of the resulting files. It can be “png”, “pdf”, “jpeg”, “bmp”, “tiff”, or “postscript”.
verbose	Logical switching log messages on and off.
...	Additional graphical parameters passed to the <code>lines</code> function drawing ellipses. In addition, for <code>e0.joint.plot.all</code> , ... contains any of the arguments of <code>e0.joint.plot</code> .

e0.map

World Map of the Life Expectancy

Description

Generates a world map of the life expectancy for given quantile and projection or estimation period.

Usage

```
e0.map(pred, ...)
```

```
e0.map.all(pred, output.dir, output.type = "png",
           e0.range = NULL, nr.cats = 50, same.scale = TRUE,
           quantile = 0.5, file.prefix = "e0wrldmap_", ...)
```

```
get.e0.map.parameters(pred, e0.range = NULL,
```

```
nr.cats = 50, same.scale = TRUE, quantile = 0.5, ...)

e0.map.gvis(pred, ...)
```

Arguments

pred	Object of class <code>bayesLife.prediction</code> .
output.dir	Directory into which resulting maps are stored.
output.type	Type of the resulting files. It can be “png”, “pdf”, “jpeg”, “bmp”, “tiff”, or “postscript”.
e0.range	Range of the life expectancy to be displayed. It is of the form <code>c(e0.min, e0.max)</code> . By default, the whole range is considered. Note that countries with values outside of the given range will appear white.
nr.cats	Number of color categories.
same.scale	Logical controlling if maps for all years of this prediction object should be on the same color scale.
quantile	Quantile for which the map should be generated. It must be equal to one of the values in <code>dimnames(pred\$quantiles[[2]])</code> , i.e. 0, 0.025, 0.05, 0.1, 0.2, 0.25, 0.3, 0.4, 0.5, 0.6, 0.7, 0.75, 0.8, 0.9, 0.95, 0.975, 1. Value 0.5 corresponds to the median.
file.prefix	Prefix for file names.
...	In <code>e0.map</code> , ... are all arguments that can be passed to <code>tfr.map</code> , such as <code>quantile</code> , <code>year</code> , <code>projection.index</code> , <code>par.name</code> , <code>adjusted</code> , <code>device</code> , <code>main</code> , <code>device.args</code> , and <code>data.args</code> . In <code>e0.map.gvis</code> , ... are all arguments that can be passed to <code>tfr.map.gvis</code> . In addition, the first three functions accept arguments passed to the <code>mapCountryData</code> function of the <code>rworldmap</code> package.

Details

`e0.map` creates a single map for the given time period and quantile. `e0.map.all` generates a sequence of maps, namely one for each projection period. If the package **fields** is installed, a color bar legend at the bottom of the map is created.

Function `get.e0.map.parameters` can be used in combination with `e0.map`. (Note that `get.e0.map.parameters` is called from inside of `e0.map.all`.) It sets breakpoints for the color scheme using quantiles of a fitted gamma distribution.

Function `e0.map.gvis` creates an interactive map using the **googleVis** package and opens it in an internet browser. It also generates a table of the mapped values that can be sorted by columns interactively in the browser.

By default, both `e0.map` and `e0.map.gvis` produce maps of life expectancy. Alternatively, the functions can be used to plot country-specific MCMC parameters into a world map. They are given by the argument `par.name`. One can pass any value from `e0.parameter.names.cs.extended()`.

Value

`get.e0.map.parameters` returns a list with elements:

pred	The object of class <code>bayesLife.prediction</code> used in the function.
quantile	Value of the argument <code>quantile</code> .
catMethod	If the argument <code>same.scale</code> is TRUE, this element contains breakpoints for categorization. It is generated from a fitted gamma distribution. Otherwise, it is NULL.
numCats	Number of categories.
colourPalette	Subset of the rainbow palette, starting from dark blue and ending at red.
...	Additional arguments passed to the function.

```

e0.median.set

Editing the Projection Medians

Description

These functions are to be used by expert analysts. They allow to change the projection medians either to specific values or shift the medians by a given constant.

Usage

```
e0.median.set(sim.dir, country, values, years = NULL, joint.male = FALSE)
```

```
e0.median.shift(sim.dir, country, reset = FALSE, shift = 0,
  from = NULL, to = NULL, joint.male = FALSE)
```

```
e0.median.reset(sim.dir, countries, joint.male = FALSE)
```

Arguments

<code>sim.dir</code>	Directory containing the prediction object.
<code>country</code>	Name or numerical code of a country.
<code>countries</code>	Vector of country names or codes.
<code>values</code>	Array of the new median values.
<code>years</code>	Numeric vector giving years which values correspond to. Ideally it should be of the same length as <code>values</code> . If it is NULL, values are set starting from the first prediction period. If values correspond to consecutive years, only the first year might be given here. A year t represents a prediction period $[t_i, t_{i+1}]$ if $t_i < t \leq t_{i+1}$.
<code>joint.male</code>	Logical. If TRUE, the function is applied to a male prediction that was generated using the joint female-male model implemented in the function <code>e0.jmale.predict</code> .
<code>reset</code>	Logical. If TRUE medians in a range of <code>from</code> and <code>to</code> are reset to their original values.
<code>shift</code>	Constant by which the medians should be offset. It is not used if <code>reset</code> is TRUE.
<code>from</code>	Year from which the offset/reset should start. By default, it starts at the first prediction period.
<code>to</code>	Year until which the offset/reset should be done. By default, it is set to the last prediction period.

Details

The function `e0.median.set` can be used to set the medians of the given country to specific values. Function `e0.median.shift` can be used to offset the medians by a specific constant, or to reset the medians to their original BHM values. Function `e0.median.reset` resets medians of the given countries to the original values. In all cases, if a median is modified, the corresponding offset is stored in the prediction object (element `median.shift`). All three functions write the updated prediction object back to disk. All functions in the package that use trajectories and trajectory statistics use the `median.shift` values to offset the results correspondingly.

Value

All three functions return an updated object of class `bayesLife.prediction`.

Hana Sevcikova

e0.parameter.names *Accessing Parameter Names*

Description

Functions for accessing names of the MCMC parameters, either country-independent or country-specific.

Usage

```
e0.parameter.names()
e0.parameter.names.cs()
e0.parameter.names.extended()
e0.parameter.names.cs.extended(country.code = NULL)
```

Arguments

`country.code` Country code. If it is given, the country-specific parameter names contain the suffix `'_cx'` where `x` is the `country.code`.

Value

`e0.parameter.names` returns names of the world parameters.
`e0.parameter.names.cs` returns names of the country-specific parameters.
`e0.parameter.names.extended` returns names of all world parameters in their extended format. I.e. parameters `'Triangle'` and `'lambda'` have the suffix `'_1'`, `'_2'`, `'_3'`, and `'_4'`.
`e0.parameter.names.cs.extended` returns names of all country-specific parameters in their extended format. I.e. parameters `'Triangle.c'` and `'lambda.c'` are in their extended format with the suffix `'_1'`, `'_2'` and `'_3'`.

e0.pardensity.plot *Plotting MCMC Parameter Density*

Description

Functions for plotting density of the posterior distribution of the MCMC parameters.

Usage

```
e0.pardensity.plot(mcmc.list = NULL,
  sim.dir = file.path(getwd(), "bayesLife.output"),
  chain.ids = NULL, par.names = e0.parameter.names(),
  burnin = NULL, dev.ncol = 5, low.memory = TRUE, ...)
```

```
e0.pardensity.cs.plot(country, mcmc.list = NULL,
  sim.dir = file.path(getwd(), "bayesLife.output"),
  chain.ids = NULL, par.names = e0.parameter.names.cs(),
  burnin = NULL, dev.ncol = 3, low.memory = TRUE, ...)
```

Arguments

country	Name or numerical code of a country.
mcmc.list	List of <code>bayesLife.mcmc</code> objects, or an object of class <code>bayesLife.mcmc.set</code> or of class <code>bayesLife.prediction</code> . If it is <code>NULL</code> , the parameter values are loaded from <code>sim.dir</code> .
sim.dir	Directory with the MCMC simulation results. It is only used if <code>mcmc.list</code> is <code>NULL</code> .
chain.ids	List of MCMC identifiers to be plotted. If it is <code>NULL</code> , all chains found in <code>mcmc.list</code> or <code>sim.dir</code> are plotted.
par.names	Names of parameters for which density should be plotted. By default all country-independent parameters are plotted if used within <code>e0.pardensity.plot</code> , or all country-specific parameters are plotted if used within <code>e0.pardensity.cs.plot</code> .
burnin	Number of iterations to be discarded from the beginning of each chain.
dev.ncol	Number of columns for the graphics device. If the number of parameters is smaller than <code>dev.ncol</code> , the number of columns is automatically decreased.
low.memory	Logical indicating if the processing should run in a memory-efficient mode.
...	Further arguments passed to the <code>density</code> function.

Details

The functions plot the density of the posterior distribution either for country-independent parameters (`e0.pardensity.plot`) or for country-specific parameters (`e0.pardensity.cs.plot`), one graph per parameter. One can restrict it to specific chains by setting the `chain.ids` argument and to specific parameters by setting the `par.names` argument.

If `mcmc.list` is an object of class `bayesLife.prediction`, thinned traces are used instead of the full chains. In such a case, `burnin` and `chain.ids` cannot be modified - their value is set to the one used when the thinned traces were created, namely when running `e0.predict`.

```

e0.partraces.plot *Plotting MCMC Parameter Traces*

Description

Functions for plotting the MCMC parameter traces.

Usage

```
e0.partraces.plot(mcmc.list = NULL,
  sim.dir = file.path(getwd(), "bayesLife.output"),
  chain.ids = NULL, par.names = e0.parameter.names(),
  nr.points = NULL, dev.ncol = 5, low.memory = TRUE, ...)

e0.partraces.cs.plot(country, mcmc.list = NULL,
  sim.dir = file.path(getwd(), "bayesLife.output"),
  chain.ids = NULL, par.names = e0.parameter.names.cs(),
  nr.points = NULL, dev.ncol = 3, low.memory = TRUE, ...)
```

Arguments

<code>country</code>	Name or numerical code of a country.
<code>mcmc.list</code>	List of <code>bayesLife.mcmc</code> objects, or an object of class <code>bayesLife.mcmc.set</code> or of class <code>bayesLife.prediction</code> . If it is <code>NULL</code> , the traces are loaded from <code>sim.dir</code> .
<code>sim.dir</code>	Directory with the MCMC simulation results. It is only used if <code>mcmc.list</code> is <code>NULL</code> .

chain.ids	List of MCMC identifiers to be plotted. If it is NULL, all chains found in <code>mcmc.list</code> or <code>sim.dir</code> are plotted.
par.names	Names of parameters for which traces should be plotted. By default all country-independent parameters are plotted if used within <code>e0.partraces.plot</code> , or country-specific parameters are plotted if used within <code>e0.partraces.cs.plot</code> .
nr.points	Number of points to be plotted. If NULL, all (stored) points are plotted, otherwise the traces are thinned evenly.
dev.ncol	Number of column for the graphics device. If the number of parameters is smaller than <code>dev.ncol</code> , the number of columns is automatically decreased.
low.memory	Logical indicating if the processing should run in a low-memory mode. If it is FALSE, traces of all available parameters are loaded into memory. Otherwise, parameters are loaded as they are needed and are not kept in the memory.
...	Additional graphical arguments. It can also contain the arguments <code>burnin</code> or <code>thin</code> .

Details

The functions plot MCMC traces either for country-independent parameters (`e0.partraces.plot`) or for country-specific parameters (`e0.partraces.cs.plot`), one graph per parameter. One can restrict it to specific chains by setting the `chain.ids` argument, and to specific parameters by setting the `par.names` argument.

e0.predict

Generating Posterior Trajectories of the Life Expectancy

Description

Using the posterior parameter samples simulated by [run.e0.mcmc](#) the function generates posterior trajectories for the life expectancy for all countries of the world.

Usage

```
e0.predict(mcmc.set = NULL, end.year = 2100,
           sim.dir = file.path(getwd(), "bayesLife.output"), replace.output = FALSE,
           predict.jmale = TRUE, nr.traj = NULL, thin = NULL, burnin = 10000,
           use.diagnostics = FALSE, save.as.ascii = 1000, start.year = NULL,
           output.dir = NULL, low.memory = TRUE, seed = NULL, verbose = TRUE, ...)
```

Arguments

mcmc.set	Object of class <code>bayesLife.mcmc.set</code> . If it is NULL, the object is loaded from the directory given by <code>sim.dir</code> .
end.year	End year of the prediction.
sim.dir	Directory with the MCMC simulation results. It should equal to the <code>output.dir</code> argument in <code>run.e0.mcmc</code> .
replace.output	Logical. If TRUE, existing predictions in <code>output.dir</code> will be replaced by results of this run.
predict.jmale	Logical controlling if a joint female-male prediction should be performed. This is done only if the underlying mcmcs in <code>sim.dir</code> correspond to a female simulation. In such a case the <code>e0.jmale.predict</code> is invoked. Arguments to this function can be passed in
nr.traj	Number of trajectories to be generated. If NULL, the argument <code>thin</code> is taken to determine the number of trajectories. If both are NULL, the number of trajectories corresponds to the minimum of the size of the parameter sample and 2000.
thin	Thinning interval used for determining the number of trajectories. Only relevant, if <code>nr.traj</code> is NULL.
burnin	Number of iterations to be discarded from the beginning of the parameter traces.
use.diagnostics	Logical determining if an existing convergence diagnostics should be used for choosing the values of <code>thin</code> and <code>burnin</code> . In such a case, arguments <code>nr.traj</code> , <code>thin</code> and <code>burnin</code> are ignored. The ‘best’ values are chosen from results of running the <code>e0.diagnose</code> function. Only diagnostics can be used that suggest a convergence of the underlying MCMCs. If there are more than one such objects, the one is chosen whose recommendation for the number of trajectories is larger and closest to 2000.
save.as.ascii	Either a number determining how many trajectories should be converted into an ASCII file, or “all” in which case all trajectories are converted. It should be set to 0, if no conversion is desired.
start.year	This argument should be only used if the start year of the prediction is before or at the present year of the MCMC run (see Details below). By default the prediction starts in the next time period after the present year (passed to <code>run.e0.mcmc</code>).
output.dir	Directory into which the resulting prediction object and the trajectories are stored. If it is NULL, it is set to either <code>sim.dir</code> , or to <code>output.dir</code> of <code>mcmc.set\$meta</code> if <code>mcmc.set</code> is given.

low.memory	Logical indicating if the prediction should run in a low-memory mode. If it is FALSE, the whole traces of all parameters, including the burnin, are loaded into memory. Otherwise, burnins are discarded and parameters are loaded as they are needed and are not kept in the memory.
seed	Seed of the random number generator. If NULL no seed is set. It can be used to generate reproducible projections.
verbose	Logical switching log messages on and off.
...	Additional arguments passed to the <code>e0.jmale.predict</code> function.

Details

The trajectories are generated using the double logistic function (Chunn et al. 2010). Parameter samples simulated via `run.e0.mcmc` are used from all chains, from which the given burnin was discarded. They are evenly thinned to match `nr.traj` or using the `thin` argument. Such thinned parameter traces, collapsed into one chain, if they do not already exist, are stored on disk into the sub-directory ‘thinned_mcmc_t_b’ where t is the value of `thin` and b the value of `burnin` (see `create.thinned.e0.mcmc`).

The projection is run for all missing values before the present year, if any. Medians over the trajectories are used as imputed values and the trajectories are discarded. The process then continues by projecting the future values where all generated trajectories are kept.

A special case is when the argument `start.year` is given that is smaller or equal the present year. In such a case, imputed missing values before present year are treated as ordinary predictions (trajectories are kept). All historical data between start year and present year are used as projections.

The resulting prediction object is saved into ‘{output.dir}/predictions’. Trajectories for all countries are saved into the same directory in a binary format, one file per country. At the end of the projection, if `save.as.ascii` is larger than 0, the function converts the given number of trajectories into a CSV file of a UN-specific format. They are selected by equal spacing (see function `convert.e0.trajectories` for more details on the conversion). In addition, two summary files are created: one in a user-friendly format, the other using a UN-specific coding of the variants and time (see `write.e0.projection.summary` for more details).

Value

Object of class `bayesLife.prediction` which is a list containing components:

quantiles	A $n \times q \times p$ array of quantile values computed on the trajectories. n is the number of countries, q is the number of quantile bounds and p is the number of projections.
traj.mean.sd	A $n \times 2 \times p$ array holding the mean of all trajectories in the first column and the standard deviation in the second column. n and p are the number of countries and number of projections, respectively.
nr.traj	Number of trajectories.
e0.matrix.reconstructed	Matrix containing imputed e0 values on spots where the original e0 matrix has missing values, i.e. between the last observed data point and the present year.
output.directory	Directory where trajectories corresponding to this prediction are stored.

nr.projections	Number of projections.
burnin	Burnin used for this prediction.
end.year	The end year of this prediction.
mcmc.set	Object of class <code>bayesLife.mcmc.set</code> used for this prediction, i.e. the burned, thinned, and collapsed MCMC chain.
joint.male	If <code>e0.jmale.predict</code> was invoked, this is an object of class <code>bayesLife.prediction</code> containing male projections. In addition to the components above, it contains elements <code>fit</code> (estimation results from <code>e0.jmale.estimate</code>) and <code>meta.changes</code> (components of <code>bayesLife.mcmc.meta</code> that differ from the female meta component).

## Not run:
m <- run.e0.mcmc(nr.chains=1, iter=50, thin=1, verbose=TRUE)
pred <- e0.predict(m, burnin=25, verbose=TRUE)
summary(pred, country="Portugal")

## End(Not run)
```

`e0.predict.extra` *Generating Posterior Trajectories of the Life Expectancy for Specific Countries or Regions*

Description

Using the posterior parameter samples the function generates posterior trajectories of the life expectancy for given countries or regions. It is intended to be used after running `run.e0.mcmc.extra`, but it can be also used for purposes of testing specific settings on one or a few countries.

Usage

```
e0.predict.extra(sim.dir = file.path(getwd(), 'bayesLife.output'),  
  prediction.dir = sim.dir, countries = NULL,  
  save.as.ascii = 1000, verbose = TRUE, ...)
```

Arguments

<code>sim.dir</code>	Directory with the MCMC simulation results.
<code>prediction.dir</code>	Directory where the prediction object and the trajectories are stored.
<code>countries</code>	Vector of country codes for which the prediction should be made. If it is NULL, the prediction is run for all countries that are included in the MCMC object but for which no prediction was generated.
<code>save.as.ascii</code>	Either a number determining how many trajectories should be converted into an ascii file, or “all” in which case all trajectories are converted. It should be set to 0, if no conversions is desired. Note that the conversion is done on all countries.
<code>verbose</code>	Logical switching log messages on and off.
<code>...</code>	Additional arguments passed to a joint female-male prediction.

Details

In order to use this function, a prediction object must exist, i.e. the function `e0.predict` must have been processed prior to using this function.

Trajectories for given countries or regions are generated and stored in binary format along with other countries (in `prediction.dir`). The existing prediction object is updated and stored in the same directory. If `save.as.ascii` is larger than zero, trajectories of ALL countries are converted to an ascii format.

If the prediction object contains joint male projections, these are also created for the given countries.

Value

Updated object of class `bayesLife.prediction`.

e0.raftery.diag *Raftery Diagnostics for Parameters of the Life Expectancy*

Description

The function computes the Raftery diagnostics for each parameter in the same way as [tfr.raftery.diag](#) of the **bayesTFR** package.

Usage

```
e0.raftery.diag(mcmc = NULL, sim.dir = file.path(getwd(), "bayesLife.output"),
  burnin = 0, country = NULL, par.names = e0.parameter.names(),
  par.names.cs = e0.parameter.names.cs(),
  country.sampling.prop = 1, verbose = TRUE, ...)
```

Arguments

mcmc	A bayesLife.mcmc or bayesLife.mcmc.set object.
sim.dir	Directory with the MCMC simulation results. Only used if mcmc is NULL.
burnin	Burnin.
country	Name or code of a country. If it is given, only country-specific parameters parameters of that country are considered.
par.names	Names of country-independent parameters for which the Raftery diagnostics should be computed.
par.names.cs	Names of country-specific parameters for which the Raftery diagnostics should be computed.
country.sampling.prop	Proportion of countries that are included in the diagnostics. It should be between 0 and 1. If it is smaller than 1, the countries are randomly sampled. It is only relevant if par.names.cs is not NULL.
verbose	Logical switching log messages on and off.
...	Additional arguments passed to the e0.coda.list.mcmc function.

Details

See [tfr.raftery.diag](#) for details. This function is called from [e0.diagnose](#).

e0.trajectories.plot *Posterior Distribution of Trajectories of Life Expectancy*

Description

The functions plot/tabulate the posterior distribution of trajectories of the life expectancy for a given country, or for all countries, including their median and given probability intervals.

Usage

```
e0.trajectories.plot(e0.pred, country, pi = c(80, 95), both.sexes = FALSE,
  nr.traj = NULL, typical.trajectory = FALSE, xlim = NULL, ylim = NULL,
  type = "b", xlab = "Year", ylab = "Life expectancy at birth", main = NULL,
  lwd = c(2, 2, 2, 2, 1), col = c('black', 'green', 'red', 'red', 'gray'),
  col2 = c('gray39', 'greenyellow', 'hotpink', 'hotpink', 'gray'),
  show.legend = TRUE, add = FALSE, ...)
```

```
e0.trajectories.plot.all(e0.pred,
  output.dir = file.path(getwd(), 'e0trajectories'),
  output.type = "png", verbose = FALSE, ...)
```

```
e0.trajectories.table(e0.pred, country, pi = c(80, 95),
  both.sexes = FALSE, ...)
```

Arguments

e0.pred	Object of class bayesLife.prediction .
country	Name or numerical code of a country.
pi	Probability interval. It can be a single number or an array. If both.sexes is TRUE the default is 95.
both.sexes	Logical or the character "A". If TRUE the distribution of both sexes is plotted into one graphics (or tabulated), provided the e0.pred is a female prediction and contains a joint male prediction as a result of running the function e0.jmale.predict . For "A" it plots/tabulates the distribution of the average life expectancy over both sexes.
nr.traj	Number of trajectories to be plotted. If NULL, all trajectories are plotted, otherwise they are thinned evenly. If both.sexes is TRUE the default is zero.
typical.trajectory	Logical. If TRUE one trajectory is shown that has the smallest distance to the median.
xlim, ylim, type, xlab, ylab, main	Graphical parameters passed to the plot function.
lwd, col, col2	Vector of five elements giving the line width and color for: 1. observed data, 2. imputed missing data, 3. median, 4. quantiles, 5. trajectories. col2 is only used if both.sexes is TRUE. In such a case, col2 is used for female lines and col is used for male lines, which in this case defaults to c('black', 'green', 'darkgreen', 'darkgreen',

show.legend	Logical controlling whether the legend should be drawn.
add	Logical controlling whether the trajectories should be plotted into a new graphic device (FALSE) or into an existing device (TRUE). One can use this argument to plot trajectories from multiple countries into one graphics.
...	Additional graphical parameters. In addition, for <code>e0.trajectories.plot.all</code> , ... contains any of the arguments of <code>e0.trajectories.plot</code> , and for <code>e0.trajectories.table</code> , ... contains the <code>pi</code> and <code>country</code> arguments.
output.dir	Directory into which resulting graphs are stored.
output.type	Type of the resulting files. It can be "png", "pdf", "jpeg", "bmp", "tiff", or "postscript".
verbose	Logical switching log messages on and off.

Details

`e0.trajectories.plot` plots posterior distribution of trajectories of life expectancy for a given country. `e0.trajectories.table` gives the same output in a tabular format.

`e0.trajectories.plot.all` creates a set of such graphs (one per country) that are stored in `output.dir`.

The median and given probability intervals are computed using all available trajectories. Thus, `nr.traj` does not influence those values - it is used only to control the number of trajectories plotted.

```

get.e0.convergence *Accessing a Convergence Object*

Description

The functions load objects of class `bayesLife.convergence` from disk that were created using the function `e0.diagnose`.

Usage

```
get.e0.convergence(sim.dir = file.path(getwd(), "bayesLife.output"),  
  thin = 225, burnin = 10000)  
  
get.e0.convergence.all(sim.dir = file.path(getwd(), "bayesLife.output"))
```

Arguments

<code>sim.dir</code>	Simulation directory used for computing the diagnostics.
<code>thin</code>	Thinning interval used with this diagnostics.
<code>burnin</code>	Burnin used for computing the diagnostics.

Details

Function `get.e0.convergence` loads an object of class `bayesLife.convergence` for the specific `thin` and `burnin`. Function `get.e0.convergence.all` loads all `bayesLife.convergence` objects available in `sim.dir`.

Value

`get.e0.convergence` returns an object of class `bayesLife.convergence`;
`get.e0.convergence.all` returns a list of objects of class `bayesLife.convergence`.

Author(s)

Hana Sevcikova

get.e0.mcmc

Accessing MCMC Results

Description

The function `get.e0.mcmc` retrieves results of an MCMC simulation and creates an object of class `bayesLife.mcmc.set`. Function `has.e0.mcmc` checks the existence of such results. Function `e0.mcmc` extracts a single chain and `e0.mcmc.list` extracts several or all chains from the simulation results.

Usage

```
get.e0.mcmc(sim.dir = file.path(getwd(), "bayesLife.output"),
            chain.ids = NULL, low.memory = TRUE, burnin = 0, verbose = FALSE)
```

```
has.e0.mcmc(sim.dir)
```

```
e0.mcmc(mcmc.set, chain.id = 1)
```

```
e0.mcmc.list(mcmc.set, chain.ids=NULL)
```

Arguments

<code>sim.dir</code>	Directory where the simulation results are stored.
<code>chain.ids</code>	Chain identifiers in case only specific chains should be included in the resulting object. By default, all available chains are included.
<code>low.memory</code>	If FALSE full MCMC traces are loaded into memory.
<code>burnin</code>	Burnin used for loading traces. Only relevant, if <code>low.memory=FALSE</code> .
<code>verbose</code>	Logical switching log messages on and off.
<code>chain.id</code>	Chain identifier.
<code>mcmc.set</code>	Object of class <code>bayesLife.mcmc.set</code> .

Value

`get.e0.mcmc` returns an object of class `bayesLife.mcmc.set`. `has.e0.mcmc` returns a logical value. `e0.mcmc` returns an object of class `bayesLife.mcmc`, and `e0.mcmc.list` returns a list of `bayesLife.mcmc` objects.

[bayesLife.mcmc.set](#)

Examples

```
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
m <- get.e0.mcmc(sim.dir)
summary(m)

# summary of the world parameters for the single chains
for(mc in e0.mcmc.list(m)) print(summary(mc, par.names.cs=NULL))
```

```
get.e0.parameter.traces
```

Accessing MCMC Parameter Traces

Description

Functions for accessing traces of the MCMC parameters, either country-independent or country-specific.

Usage

```
get.e0.parameter.traces(mcmc.list, par.names = e0.parameter.names(),
  burnin = 0, thinning.index = NULL, thin = NULL)

get.e0.parameter.traces.cs(mcmc.list, country.obj,
  par.names = e0.parameter.names.cs(),
  burnin = 0, thinning.index = NULL, thin = NULL)
```

Arguments

mcmc.list	List of bayesLife.mcmc objects.
country.obj	Country object list (see get.country.object).
par.names	Names of country-independent parameters (in case of <code>get.e0.parameter.traces</code>) or country-specific parameters (in case of <code>get.e0.parameter.traces.cs</code>) to be included.
burnin	Burnin indicating how many iterations should be removed from the beginning of each chain.
thinning.index	Index of the traces for thinning. If it is NULL, <code>thin</code> is used. <code>thinning.index</code> does not include <code>burnin</code> and should be flattened over all chains. For example, if there are two MCMC chains of length 1000, <code>burnin=200</code> and we want a sample of length 400, then the value should be <code>thinning.index=seq(1,1600, length=400)</code> .
thin	Alternative to <code>thinning.index</code> . The above example is equivalent to <code>thin=4</code> .

Value

Both functions return a matrix with columns being the parameters and rows being the MCMC values, attached to one another in case of multiple chains. `get.e0.parameter.traces` returns country-independent parameters, `get.e0.parameter.traces.cs` returns country-specific parameters.

Author(s)

Hana Sevcikova

See Also[e0.coda.list.mcmc](#) for another way of retrieving parameter traces.**Examples**

```
## Not run:
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
m <- get.e0.mcmc(sim.dir)
e0.values <- get.e0.parameter.traces(m$mcmc.list, burnin=10, par.names="z")
hist(e0.values, main=colnames(e0.values))

e0.values.cs <- get.e0.parameter.traces.cs(m$mcmc.list,
                                          get.country.object("Canada", meta=m$meta),
                                          burnin=10, par.names="z.c")
hist(e0.values.cs, main=colnames(e0.values.cs))
## End(Not run)
```

get.e0.prediction *Accessing a Prediction Object*

Description

Function `get.e0.prediction` retrieves results of a prediction and creates an object of class [bayesLife.prediction](#). Function `has.e0.prediction` checks an existence of such results. Analogously, functions `get.e0.jmale.prediction` and `has.e0.jmale.prediction` retrieve and check an existence of male predictions from a given female prediction object.

Usage

```
get.e0.prediction(mcmc = NULL, sim.dir = NULL, joint.male = FALSE, mcmc.dir = NULL)
```

```
has.e0.prediction(mcmc = NULL, sim.dir = NULL)
```

```
get.e0.jmale.prediction(e0.pred)
```

```
has.e0.jmale.prediction(e0.pred)
```

Arguments

mcmc	Object of class bayesLife.mcmc.set used to make the prediction. If it is NULL, the prediction is loaded from directory given by <code>sim.dir</code> .
sim.dir	Directory where the prediction is stored. It should correspond to the value of the <code>output.dir</code> argument used in the e0.predict function. Only relevant if <code>mcmc</code> is NULL.

joint.male	Logical. If TRUE, the function is applied to a male prediction that was generated using the joint female-male model implemented in the function <code>e0.jmale.predict</code> .
mcmc.dir	Optional argument to be used only in a special case when the mcmc object contained in the prediction object was estimated in different directory than in the one to which it points to (for example due to moving or renaming the original directory). The argument causes that the mcmc is redirected to the given directory.
e0.pred	Object of class <code>bayesLife.prediction</code> .

Details

If mcmc is not NULL, the search directory is set to `mcmc$meta$output.dir`. This approach assumes that the prediction was stored in the same directory as the MCMC simulation, i.e. the `output.dir` argument of the `e0.predict` function was set to NULL. If it is not the case, the argument `mcmc.dir` should be used.

Function `get.e0.jmale.prediction` extracts male projections from the `e0.pred` objects (which should be a female prediction object), if the male prediction was generated using the `e0.jmale.predict` function. `has.e0.jmale.prediction` checks if such male prediction was generated.

Value

Functions `has.e0.prediction` and `has.e0.jmale.prediction` return a logical indicating if a prediction exists.

Functions `get.e0.prediction` and `get.e0.jmale.prediction` return an object of class `bayesLife.prediction`.

pred <- get.e0.prediction(sim.dir=sim.dir)
summary(pred, country="Canada")
```

get.e0.trajectories *Accessing Trajectories of Life Expectancy*

Description

Function for accessing trajectories of the life expectancy.

Usage

```
get.e0.trajectories(e0.pred, country)
```

Arguments

<code>e0.pred</code>	Object of class bayesLife.prediction .
<code>country</code>	Name or numerical code of a country.

Details

The function loads trajectories of life expectancy for the given country from disk and returns it as a matrix.

Value

Array of size the number of projection periods (including the present year) times the number of trajectories. The row names correspond to the mid-years of the prediction periods.

Author(s)

Hana Sevcikova

[bayesLife.prediction](#), [get.e0.prediction](#), [e0.trajectories.table](#)

Examples

```
sim.dir <- file.path(find.package("bayesLife"), "ex-data", "bayesLife.output")
pred <- get.e0.prediction(sim.dir=sim.dir)
get.e0.trajectories(pred, "Germany")
```

`get.thinned.e0.mcmc` *Creating and Accessing Thinned MCMCs*

Description

The function `get.thinned.e0.mcmc` accesses a thinned and burned version of the given MCMC set. `create.thinned.e0.mcmc` creates such set.

Usage

```
get.thinned.e0.mcmc(mcmc.set, thin = 1, burnin = 0)

create.thinned.e0.mcmc(mcmc.set, thin = 1, burnin = 0,
  output.dir = NULL, verbose = TRUE)
```

Arguments

mcmc.set	Object of class bayesLife.mcmc.set .
thin, burnin	Thinning interval and burnin used for creating or identifying the thinned object.
output.dir	Directory for storing the thinned object. By default it is stored into the same directory as mcmc.set.
verbose	Logical switching log messages on and off.

Details

The function `create.thinned.e0.mcmc` is called from `e0.predict` and thus, the resulting object contains exactly the same MCMCs used for generating projections.

The thinning is done as follows: The given burnin is removed from the beginning of each chain in the original MCMC set. Then each chain is thinned by `thin` using equal spacing and all chains are collapsed into one single chain per parameter. They are stored in `output.dir` under the name `'thinned_mcmc_t_b'` where `t` is the value of `thin` and `b` the value of `burnin`.

Value

Both functions return an object of class [bayesLife.mcmc.set](#). `get.thinned.e0.mcmc` returns NULL if such object does not exist.

Author(s)

Hana Sevcikova

mb <- get.thinned.e0.mcmc(m, thin=2, burnin=30)
summary(mb, meta.only=TRUE) # length 30 = 2chains x (60-30)iters./2thin
unlink(sim.dir, recursive=TRUE)

## End(Not run)
```

include	<i>Inclusion Codes</i>
---------	------------------------

Description

Data sets containing codes that determine which countries are to be included into a simulation or/and projections.

Usage

```
data(include_2008)
data(include_2010)
data(include_2012)
```

Format

Data frames containing one record per country or region. It has the following variables:

`country` Name of country or region. Not used.

`country_code` Numerical Location Code (3-digit codes following ISO 3166-1 numeric standard) - see http://en.wikipedia.org/wiki/ISO_3166-1_numeric.

include_code Entries for which `include_code=2` are included in MCMC simulations (i.e. estimation of the model parameters). Entries for which `include_code` is 1 or 2 are included in the prediction.

Details

In a simulation, an `include_*` dataset is selected that corresponds to the given `wpp.year` passed to the function `run.e0.mcmc`. It is merged with a `e0` dataset from the corresponding `wpp` package using the `country_code` column. Thus, the country entries in this dataset should correspond to entries in the `e0F` (`e0M`) dataset.

The package contains also a dataset called `'my_e0_template'` (in `'extdata'` directory) which is a template for user-specified `e0` time series. It has the same structure as the `e0` dataset, except that most of the columns are optional. The only required column is `country_code` (see description of the argument `my.e0.file` in `run.e0.mcmc`).

Note

In all three datasets, countries affected by AIDS are not included in the estimation, i.e. the `include_code` is set to 3.

Source

Data provided by the United Nations Population Division.

Examples

```
data(include_2012)
head(include_2012)
```

run.e0.mcmc	<i>Running Markov Chain Monte Carlo for Parameters of Life Expectancy</i>
-------------	---

Description

Runs (or continues running) MCMCs for simulating the life expectancy for all countries of the world, using a Bayesian hierarchical model.

Usage

```
run.e0.mcmc(sex = c("Female", "Male"), nr.chains = 3, iter = 160000,
  output.dir = file.path(getwd(), "bayesLife.output"),
  thin = 10, replace.output = FALSE,
  start.year = 1873, present.year = 2010, wpp.year = 2012,
  my.e0.file = NULL, buffer.size = 100,
  a = c(13.215, 41.070, 9.235, 17.605, 2.84, 0.385),
  delta = c(3.844, 4.035, 11.538, 5.639, 0.901, 0.4),
  tau = c(15.5976503, 23.650006, 14.5056919,
    14.718598, 3.4514285, 0.5667531),
  Triangle.ini = list(NULL, NULL, NULL, NULL), k.ini = NULL,

  verbose = FALSE, verbose.iter = 10, ...)

```

Arguments

sex	Sex for which to run the simulation.
nr.chains	Number of MCMC chains to run.
iter	Number of iterations to run in each chain. In addition to a single value, it can have the value 'auto' in which case the function runs for the number of iterations given in the auto.conf list (see below), then checks if the MCMCs converged (using the auto.conf settings). If it did not converge, the procedure is repeated until convergence is reached or the number of repetition exceeded auto.conf\$max.loops.
output.dir	Directory which the simulation output should be written into.
thin	Thinning interval between consecutive observations to be stored on disk.
replace.output	If TRUE, existing outputs in output.dir will be replaced by results of this simulation.
start.year	Start year for using historical data.
present.year	End year for using historical data.
wpp.year	Year for which WPP data is used. The functions loads a package called wppx where x is the wpp.year and uses the e0* datasets.
my.e0.file	File name containing user-specified e0 time series for one or more countries. See Details below.
buffer.size	Buffer size (in number of [thinned] iterations) for keeping data in the memory. The smaller the buffer.size the more often will the process access the hard disk and thus, the slower the run. On the other hand, the smaller the buffer.size the less data will be lost in case of failure.
a	A vector of the a_1, \dots, a_6 parameters, which are the prior means of the world-level parameters $(\Delta_1, \dots, \Delta_4, k, z)$.
delta	A vector of the $\delta_1, \dots, \delta_6$ parameters, which are the prior standard deviations of the world-level parameters $(\Delta_1, \dots, \Delta_4, k, z)$.
tau	A vector of the τ_1, \dots, τ_6 parameters, which is the square root rate of the prior Gamma distribution of the world-level parameters $(\lambda_1, \dots, \lambda_4, \lambda_k, \lambda_z)$.
Triangle.ini	List (of length four) of initial values for $\Delta_1, \dots, \Delta_4$. Each list item should be of the length nr.chains. If a list item is NULL, the initial values are equally spaced between Triangle.ini.low and Triangle.ini.up. By default, if there is just one chain, the value is the middle point of the interval.
k.ini, z.ini	An array of length nr.chains of initial values for $k(z)$. By default, the initial values are equally spaced between k.ini.low and k.ini.up (z.ini.low and z.ini.up). If nr.chains=1 and k.ini (z.ini) is NULL, the initial value is the middle point of the interval.

lambda.ini	List (of length four) of initial values for $\lambda_1, \dots, \lambda_4$. Each list item should be of the length nr.chains. If a list item is NULL, the initial values are equally spaced between lambda.ini.low and lambda.ini.up. By default, if there is just one chain, the value is the middle point of the interval.
lambda.k.ini, lambda.z.ini	An array of length nr.chains of initial values for λ_k (λ_z). By default, the initial values are equally spaced between lambda.k.ini.low and lambda.k.ini.up (lambda.z.ini.low and lambda.z.ini.up). If nr.chains=1 and lambda.k.ini (lambda.z.ini) is NULL, the initial value is the middle point of the interval.
omega.ini	An array of length nr.chains of initial values for ω . By default, the initial values are equally spaced between omega.ini.low and omega.ini.up. If nr.chains=1 and omega.ini is NULL, the initial value is the middle point of the interval.
Triangle.ini.low, Triangle.ini.up	A vector of length four. They are the lower and upper bounds for initial values of $\Delta_1, \dots, \Delta_4$. An i -th item is only used if Triangle.ini[[i]] is NULL.
k.ini.low, k.ini.up	Single value giving the lower and upper bounds for initial values of k . It is only used if k.ini is NULL.
z.ini.low, z.ini.up	Single value giving the lower and upper bounds for initial values of z . It is only used if z.ini is NULL. Regarding defaults, see Note below.
lambda.ini.low, lambda.ini.up	A vector of length four. They are the lower and upper bounds for initial values of $\lambda_1, \dots, \lambda_4$. An i -th item is only used if lambda.ini[[i]] is NULL.
lambda.k.ini.low, lambda.k.ini.up	Single value giving the lower and upper bounds for initial values of λ_k . It is only used if lambda.k.ini is NULL.
lambda.z.ini.low, lambda.z.ini.up	Single value giving the lower and upper bounds for initial values of λ_z . It is only used if lambda.z.ini is NULL.
omega.ini.low, omega.ini.up	Single value giving the lower and upper bounds for initial values of ω . It is only used if omega.ini is NULL.
Triangle.prior.low, Triangle.prior.up	A vector of length four. They are the lower and upper bounds for the prior (truncated normal) distribution of $\Delta_1, \dots, \Delta_4$.
k.prior.low, k.prior.up	Single value giving the lower and upper bounds for the prior (truncated normal) distribution of k .
z.prior.low, z.prior.up	Single value giving the lower and upper bounds for the prior (truncated normal) distribution of z . Regarding defaults, see Note below.
Triangle.c.ini.norm	A list with two elements, each of them being a vector of size four. The first and second element in the list corresponds to the means and standard deviation,

	respectively, for the initial values of the country-specific parameters $\Delta_1^c, \dots, \Delta_4^c$ which are drawn from a truncated normal distribution with bounds defined by <code>Triangle.c.prior.low</code> and <code>Triangle.c.prior.up</code> .
<code>k.c.ini.norm, z.c.ini.norm</code>	A vector of length two. The first and second element corresponds to the means and standard deviation, respectively, for the initial values of the country-specific parameters k^c (z^c) which are drawn from a normal distribution truncated between <code>k.c.prior.low</code> and <code>k.c.prior.up</code> (<code>z.c.prior.low</code> and <code>z.c.prior.up</code>).
<code>Triangle.c.prior.low, Triangle.c.prior.up</code>	A vector of length four. They are the lower and upper bounds for the prior (truncated normal) distribution of country-specific $\Delta_1^c, \dots, \Delta_4^c$.
<code>k.c.prior.low, k.c.prior.up</code>	Single value giving the lower and upper bounds for the prior (truncated normal) distribution of country-specific k^c .
<code>z.c.prior.low, z.c.prior.up</code>	Single value giving the lower and upper bounds for the prior (truncated normal) distribution of country-specific z^c . Regarding defaults, see Note below.
<code>country.overwrites</code>	This argument allows to overwrite some of the prior parameters for specific countries. If it is not NULL it should be a data frame with an obligatory column 'country_code'. Each row then corresponds to one country. Other columns can be 'k.c.prior.low', 'k.c.prior.up', 'z.c.prior.low', 'z.c.prior.up', 'Triangle_x.c.prior.low' and 'Triangle_x.c.prior.up' where x can be an integer from 1 to 4.
<code>nu</code>	The shape parameter of the Gamma distributions of all λ parameters is <code>nu/2</code> .
<code>dl.p1, dl.p2</code>	Values of the parameters p_1 and p_2 of the double logistic function.
<code>sumTriangle.lim</code>	Lower and upper limits for the sum of the Δ_i parameters. MCMC proposals that are outside of this limit are rejected. It is applied to both, the world parameters as well as the country specific parameters.
<code>constant.variance</code>	Logical indicating if the model should be estimated using constant variance.
<code>seed</code>	Seed of the random number generator. If NULL no seed is set. It can be used to generate reproducible results.
<code>parallel</code>	Logical determining if the simulation should run multiple chains in parallel. If it is TRUE, the package snowFT is required.
<code>nr.nodes</code>	Relevant only if <code>parallel</code> is TRUE. It gives the number of nodes for running the simulation in parallel. By default it equals to the number of chains.
<code>compression.type</code>	One of 'None', 'gz', 'xz', 'bz', determining type of a compression of the MCMC files.
<code>auto.conf</code>	List containing a configuration for an 'automatic' run (see description of argument <code>iter</code>). Item <code>iter</code> gives the number of iterations in the first chunk of the MCMC simulation; item <code>iter.incr</code> gives the number of iterations in the following chunks; <code>nr.chains</code> gives the number of chains in all chunks of the MCMC simulation; items <code>thin</code> and <code>burnin</code> are used in the convergence diagnostics following each chunk; <code>max.loops</code> controls the maximum number of

	chunks. All items must be integer values. This argument is only used if the function argument <code>iter</code> is set to 'auto'.
<code>verbose</code>	Logical switching log messages on and off.
<code>verbose.iter</code>	Integer determining how often (in number of iterations) log messages are outputted during the estimation.
<code>...</code>	Additional parameters to be passed to the function <code>performParallel</code> , if <code>parallel</code> is TRUE.
<code>chain.ids</code>	Array of chain identifiers that should be resumed. If it is NULL, all existing chains in <code>output.dir</code> are resumed.

Details

The function `run.e0.mcmc` creates an object of class `bayesLife.mcmc.meta` and stores it in `output.dir`. It launches `nr.chains` MCMCs, either sequentially or in parallel. Parameter traces of each chain are stored as (possibly compressed) ASCII files in a subdirectory of `output.dir`, called `mcx` where `x` is the identifier of that chain. There is one file per parameter, named after the parameter with the suffix ".txt", possibly followed by a compression suffix if `compression.type` is given. Country-specific parameters have the suffix `_countryc` where `c` is the country code. In addition to the trace files, each `mcx` directory contains the object `bayesLife.mcmc` in binary format. All chain-specific files are written into disk after the first, last and each `buffer.size`-th (thinned) iteration.

Using the function `continue.e0.mcmc` one can continue simulating an existing MCMCs by `iter` iterations for either all or selected chains.

The function loads observed data (further denoted as WPP dataset) from the `e0M(e0F)` and `e0M_supplemental(e0F_supplemental)` datasets in a `wppx` package where `x` is the `wpp.year`. It is then merged with the `include` dataset that corresponds to the same `wpp.year`. The argument `my.e0.file` can be used to overwrite those default data. Such a file can include a subset of countries contained in the WPP dataset, as well as a set of new countries. In the former case, the function replaces the corresponding country data from the WPP dataset by values in this file. Only columns are replaced that match column names of the WPP dataset, and in addition, columns 'last.observed' and 'include_code' are used, if present. Countries are merged with WPP using the column 'country_code'. In addition, in order the countries to be included in the simulation, in both cases (whether they are included in the WPP dataset or not), they must be contained in the UN table of locations (`UNlocations`). In addition, their corresponding 'include_code' must be set to 2. If the column 'include_code' is present in `my.e0.file`, its value overwrites the default include code, unless is -1.

For simulation of the hyperparameters of the Bayesian hierarchical model, all countries are used that are included in the WPP dataset, possibly complemented by the `my.e0.file`, that have `include_code` equal to 2. The hyperparameters are used to simulate country-specific parameters, which is done for all countries with `include_code` equal 1 or 2. The following values of `include_code` in `my.e0.file` are recognized: -1 (do not overwrite the default include code), 0 (ignore), 1 (include in prediction but not estimation), 2 (include in both, estimation and prediction). Thus, the set of countries included in the estimation and prediction can be fully specified by the user.

Optionally, `my.e0.file` can contain a column called `last.observed` containing the year of the last observation for each country. In such a case, the code would ignore any data after that time point. Furthermore, the function `e0.predict` fills in the missing values using the median of the BHM procedure (stored in `e0.matrix.reconstructed` of the `bayesLife.prediction` object). For `last.observed` values that are below a middle year of a time interval $[t_i, t_{i+1}]$ (computed as

$t_i + 3$) the last valid data point is the time interval $[t_{i-1}, t_i]$, whereas for values larger equal a middle year, the data point in $[t_i, t_{i+1}]$ is valid.

The package contains a dataset called 'my_e0_template' (in 'extdata' directory) which is a template for user-specified my.e0.file.

Value

An object of class `bayesLife.mcmc.set` which is a list with two components:

<code>meta</code>	An object of class <code>bayesLife.mcmc.meta</code> .
<code>mcmc.list</code>	A list of objects of class <code>bayesLife.mcmc</code> , one for each MCMC.

Note

Parameter z determines the asymptote in gains in life expectancy. The following text gives an explanation for the choice of upper limits on z -related parameters:

The pace of improvement and the asymptotic limit in future gains in female life expectancy vary for each projected trajectory, but ultimately is informed and constrained by the finding that the rate of increase of maximum female life expectancy over the past 150 year has been highly linear (2a, 2b) (i.e., about 2.4 years per decade), albeit at slightly lower pace once the leading countries started to exceed 75 years of female life expectancy at birth in the 1960s (3) (about 2.26 years of gains per decade). By assuming that the asymptotic average rate of increase in life expectancy is nonnegative, life expectancy is assumed to continually increase (on average), and no limit is imposed to life expectancy in the foreseeable future. The increase in maximum female life span among countries with highest life expectancy and reliable data on very old age provide further guidance on future rate of progress which has also been increasingly linear at least since the 1970s (4a-4c) (about 1.25 years per decade for countries like Sweden and Norway), and is used to inform the asymptotic average rate of increase in female life expectancy used in the 2012 WPP Revision. To set the posterior median to an annual gain of 0.125 year (or 5-year gain of 0.625 in this context) the upper bound value of 0.653 is used for the world prior (z) and country-specific prior (z_c) as default values in the estimation of the double-logistic parameters.

## End(Not run)
```

run.e0.mcmc.extra *Run MCMC for Extra Countries, Areas or Regions*

Description

Run MCMC for extra countries, areas or regions. It uses the posterior distribution of model hyperparameters from an existing simulation to generate country-specific parameters.

Usage

```
run.e0.mcmc.extra(sim.dir = file.path(getwd(), "bayesLife.output"),
  countries = NULL, my.e0.file = NULL,
  iter = NULL, thin = 1, burnin = 2000, country.overwrites = NULL,
  parallel = FALSE, nr.nodes = NULL, verbose = FALSE, verbose.iter = 100, ...)
```

Arguments

<code>sim.dir</code>	Directory with an existing simulation.
<code>countries</code>	Vector of country codes. These include codes of areas and regions (see column <code>country_code</code> in UNlocations).
<code>my.e0.file</code>	File name containing user-specified time series of life expectancy for countries for which the simulation should run (see Details below).
<code>iter</code>	Number of iterations to be used for sampling from the posterior distribution of the hyperparameters. By default, the number of (possibly thinned) iterations used in the existing simulation is taken.
<code>thin</code>	Thinning interval for sampling from the posterior distribution of the hyperparameters.

burnin	Number of iterations discarded before sampling from the posterior distribution of the hyperparameters.
country.overwrites	This argument allows to overwrite some of the prior parameters for specific countries. If it is not NULL it should be a data frame with an obligatory column 'country_code'. Each row then corresponds to one country. Other columns can be 'k.c.prior.low', 'k.c.prior.up', 'z.c.prior.low', 'z.c.prior.up', 'Triangle_x.c.prior.low' and 'Triangle_x.c.prior.up' where <i>x</i> can be an integer from 1 to 4. Rows corresponding to countries that are not processed in this function are ignored.
parallel	Logical determining if the simulation should run multiple chains in parallel.
nr.nodes	Relevant only if parallel is TRUE. It gives the number of nodes for running the simulation in parallel. By default it equals to the number of chains contained in the existing simulation.
verbose	Logical switching log messages on and off.
verbose.iter	Integer determining how often (in number of iterations) log messages are outputted during the estimation.
...	Additional parameters to be passed to the function <code>performParallel</code> , if parallel is TRUE.

Details

The function can be used to make predictions for countries, areas or regions (further denoted as 'countries') that were not included in the MCMC estimation (invoked by `run.e0.mcmc`). It creates MCMC traces for country-specific parameters. The purpose of this function is to have country-specific parameters available in order to be able to generate projections for additional countries or their aggregations, without having to re-run the often time-expensive MCMC simulation.

The set of countries to be considered by this function can be given either by their codes, using the argument `countries`, in which case the countries must be included in the UN WPP `e0` dataset. Or, it can be given by a user-specific file, using the argument `my.e0.file`. The function considers a union of both arguments. The function will ignore all countries that were used in the existing MCMC simulation for estimating the hyperparameters. Countries that already own country-specific parameters (e.g. because they were included in `my.e0.file` passed to `run.e0.mcmc`) get their parameters recomputed. Note that all countries must be included in the `UNlocations` dataset, but unlike in `run.e0.mcmc`, their `include_code` is ignored.

Value

An object of class `bayesLife.mcmc.set`.

Note

If there is an existing projection for the directory `sim.dir`, use `e0.predict.extra` to obtain projections for the extra countries used in this function.

summary.bayesLife.convergence

Summary of a Life Expectancy Convergence Object

Description

Summary of an object of class [bayesLife.convergence](#) created using the [e0.diagnose](#) function. It gives an overview about parameters that did not converge.

Usage

```
## S3 method for class 'bayesLife.convergence'
summary(object, expand = FALSE, ...)
```

Arguments

object	Object of class bayesLife.convergence .
expand	By default, the function does not show parameters for each country for which there was no convergence, if the status is 'red'. This argument can switch that option on.
...	Not used.

[e0.diagnose](#)

summary.bayesLife.mcmc.set

Summary Statistics for Life Expectancy MCMCs

Description

Summary of an object [bayesLife.mcmc.set](#) or [bayesLife.mcmc](#), computed via [run.e0.mcmc](#). It can be obtained either for all countries or for a specific country, and either for all parameters or for specific parameters. The function uses the [summary.mcmc](#) function of the **coda** package.

Usage

```
## S3 method for class 'bayesLife.mcmc.set'
summary(object, country = NULL, chain.id = NULL,
        par.names = e0.parameter.names(),
        par.names.cs = e0.parameter.names.cs(),
        meta.only = FALSE, thin = 1, burnin = 0, ...)

## S3 method for class 'bayesLife.mcmc'
summary(object, country = NULL,
        par.names = e0.parameter.names(),
        par.names.cs = e0.parameter.names.cs(), ...)
```

Arguments

object	Object of class bayesLife.mcmc.set or bayesLife.mcmc .
country	Country name or code if a country-specific summary is desired.
chain.id	Identifiers of MCMC chains. By default, all chains are considered.
par.names	Country independent parameters to be included in the summary.
par.names.cs	Country-specific parameters to be included in the summary.
meta.only	Logical. If it is TRUE, only meta information of the simulation is included.
thin	Thinning interval. Only used if larger than the thin argument used in run.e0.mcmc .
burnin	Number of iterations to be discarded from the beginning of each chain before computing the summary.
...	For summary.bayesLife.mcmc , arguments thin and burnin can be passed here. In addition, both functions accept arguments passed to the summary.mcmc function of the coda package.

summary.bayesLife.prediction

Summary of a Prediction of the Life Expectancy

Description

Country-specific summary of an object of class [bayesLife.prediction](#), created using the function [e0.predict](#). The summary contains the mean, standard deviation and several commonly used quantiles of the simulated trajectories.

Usage

```
## S3 method for class 'bayesLife.prediction'
summary(object, country = NULL, compact = TRUE, ...)
```

Arguments

object	Object of class bayesLife.prediction .
country	Country name or code.
compact	Logical switching between a smaller and larger number of displayed quantiles.
...	Not used.

pred <- get.e0.prediction(sim.dir=sim.dir)
summary(pred, country="Iceland")
```

 write.e0.projection.summary

Writing Projection Summary Files

Description

The function creates two files containing projection summaries, such as the median, the lower and upper bound of the 80 and 90% probability intervals, respectively, and the constant variant. One file is in a user-friendly format, whereas the other is in a UN-specific format with internal coding of the time and the variants.

Usage

```
write.e0.projection.summary(dir = file.path(getwd(), "bayesLife.output"),
  output.dir = NULL, revision = NULL, adjusted = FALSE)
```

Arguments

dir	Directory containing the prediction object. It should correspond to the <code>output.dir</code> argument of the <code>e0.predict</code> function.
output.dir	Directory in which the resulting file will be stored. If <code>NULL</code> the same directory is used as for the prediction.
revision	UN revision number. If <code>NULL</code> it is determined from the corresponding WPP year: WPP 2008 corresponds to revision 13, every subsequent WPP increases the revision number by one. Used as a constant in the second file only.
adjusted	Logical. By default the function writes summary using the original BHM projections. If the projection medians are adjusted (using e.g. <code>e0.median.set</code>), setting this argument to <code>TRUE</code> causes writing the adjusted projections.

Details

The first file that the function creates is called ‘projection_summary_user_friendly.csv’, it is a comma-separated table with the following columns:

- “country_name”: country name
- “country_code”: country code
- “variant”: name of the variant, such as “median”, “lower 80”, “upper 80”, “lower 95”, “upper 95”, “constant”
- period1: e.g. “2005-2010”: life expectancy for the first time period
- period2: e.g. “2010-2015”: life expectancy for the second time period
- ... further columns with life expectancy projections

The second file, called ‘projection_summary.csv’, also comma-separated table, contains the same information as above in a UN-specific format:

- “RevID”: revision number, passed to the function as an argument;

- “VarID”: variant identifier, extracted from the [UN_variants](#) dataset in the **bayesTFR** package;
- “LocID”: country code;
- “TimeID”: time identifier, extracted from the [UN_time](#) dataset in the **bayesTFR** package;
- “e0”: the life expectancy for this variant, location and time period.

If the simulation directory contains joint male predictions, summary files for those are created as well. In such a case, if `output.dir` is given, separate subdirectories for female and male are created.

Note

This function is automatically called from the [e0.predict](#) and [e0.jmale.predict](#) functions, therefore in standard cases it will not be needed to call it directly.

Author(s)

Hana Sevcikova
