

Package ‘sandwich’

August 24, 2014

Version 2.3-2

Date 2014-08-24

Title Robust Covariance Matrix Estimators

Description

Model-robust standard error estimators for cross-sectional, time series, and longitudinal data.

Depends R (>= 2.0.0)

Imports stats, zoo

Suggests car, lmtest, strucchange, AER, survival, MASS, scatterplot3d

License GPL-2 | GPL-3

Author Thomas Lumley [aut], Achim Zeileis [aut, cre]

bread	<i>Bread for Sandwiches</i>
-------	-----------------------------

Description

Generic function for extracting an estimator for the bread of sandwiches.

Usage

```
bread(x, ...)
```

Arguments

x	a fitted model object.
...	arguments passed to methods.

Value

A matrix containing an estimator for the expectation of the negative derivative of the estimating functions, usually the Hessian. Typically, this should be an $k \times k$ matrix corresponding to k parameters. The rows and columns should be named as in `coef` or `terms`, respectively.

References

Examples

```
## linear regression
x <- sin(1:10)
y <- rnorm(10)
fm <- lm(y ~ x)

## bread: n * (x'x)^{-1}
bread(fm)
solve(crossprod(cbind(1, x))) * 10
```

`estfun`*Extract Empirical Estimating Functions*

Description

Generic function for extracting the empirical estimating functions of a fitted model.

Usage

```
estfun(x, ...)
```

Arguments

`x` a fitted model object.
`...` arguments passed to methods.

Value

A matrix containing the empirical estimating functions. Typically, this should be an $n \times k$ matrix corresponding to n observations and k parameters. The columns should be named as in `coef` or `terms`, respectively.

The estimating function (or score function) for a model is the derivative of the objective function with respect to the parameter vector. The empirical estimating functions is the evaluation of the estimating function at the observed data (n observations) and the estimated parameters (of dimension k).

estfun(fm)
residuals(fm) * cbind(1, x)
```

Investment

*US Investment Data***Description**

US data for fitting an investment equation.

Usage

```
data(Investment)
```

Format

An annual time series from 1963 to 1982 with 7 variables.

GNP nominal gross national product (in billion USD),

Investment nominal gross private domestic investment (in billion USD),

Price price index, implicit price deflator for GNP,

Interest interest rate, average yearly discount rate charged by the New York Federal Reserve Bank,

RealGNP real GNP (= GNP/Price),

RealInv real investment (= Investment/Price),

RealInt approximation to the real interest rate (= Interest - 100 * diff(Price)/Price).

}

```

isoacf

Isotonic Autocorrelation Function

Description

Autocorrelation function (forced to be decreasing by isotonic regression).

Usage

```
isoacf(x, lagmax = NULL, weave1 = FALSE)
```

Arguments

x	numeric vector.
lagmax	numeric. The maximal lag of the autocorrelations.
weave1	logical. If set to TRUE isoacf uses the acf.R and pava.blocks function from the original weave package, otherwise R's own acf and isoreg functions are used.

Details

isoacf computes the autocorrelation function (ACF) of x enforcing the ACF to be decreasing by isotonic regression. See also Robertson et al. (1988).

Value

isoacf returns a numeric vector containing the ACF.

kweights

Kernel Weights

Description

Kernel weights for kernel-based heteroskedasticity and autocorrelation consistent (HAC) covariance matrix estimators as introduced by Andrews (1991).

Usage

```
kweights(x, kernel = c("Truncated", "Bartlett", "Parzen",
  "Tukey-Hanning", "Quadratic Spectral"), normalize = FALSE)
```

Arguments

x	numeric.
kernel	a character specifying the kernel used. All kernels used are described in Andrews (1991).
normalize	logical. If set to TRUE the kernels are normalized as described in Andrews (1991).

Value

Value of the kernel function at x .

      from = 0, to = 3.2, col = 5, add = TRUE)
```

 Irvar

Long-Run Variance of the Mean

Description

Convenience function for computing the long-run variance (matrix) of a (possibly multivariate) series of observations.

Usage

```
Irvar(x, type = c("Andrews", "Newey-West"), prewhite = TRUE, adjust = TRUE, ...)
```

Arguments

<code>x</code>	numeric vector, matrix, or time series.
<code>type</code>	character specifying the type of estimator, i.e., whether kernHAC for the Andrews quadratic spectral kernel HAC estimator is used or NeweyWest for the Newey-West Bartlett HAC estimator.
<code>prewhite</code>	logical or integer. Should the series be prewhitened? Passed to kernHAC or NeweyWest .
<code>adjust</code>	logical. Should a finite sample adjustment be made? Passed to kernHAC or NeweyWest .
<code>...</code>	further arguments passed on to kernHAC or NeweyWest .

Details

lrvar is a simple wrapper function for computing the long-run variance (matrix) of a (possibly multivariate) series x . First, this simply fits a linear regression model $x \sim 1$ by `lm`. Second, the corresponding variance of the mean(s) is estimated either by `kernHAC` (Andrews quadratic spectral kernel HAC estimator) or by `NeweyWest` (Newey-West Bartlett HAC estimator).

Value

For a univariate series x a scalar variance is computed. For a multivariate series x the covariance matrix is computed.

See Also

[kernHAC](#), [NeweyWest](#), [vcovHAC](#)

Examples

```
set.seed(1)
## iid series (with variance of mean 1/n)
## and Andrews kernel HAC (with prewhitening)
x <- rnorm(100)
lrvar(x)

## analogous multivariate case with Newey-West estimator (without prewhitening)
y <- matrix(rnorm(200), ncol = 2)
lrvar(y, type = "Newey-West", prewhite = FALSE)

## AR(1) series with autocorrelation 0.9
z <- filter(rnorm(100), 0.9, method = "recursive")
lrvar(z)
```

meat

A Simple Meat Matrix Estimator

Description

Estimating the variance of the estimating functions of a regression model by cross products of the empirical estimating functions.

Usage

```
meat(x, adjust = FALSE, ...)
```

Arguments

- `x` a fitted model object.
- `adjust` logical. Should a finite sample adjustment be made? This amounts to multiplication with
- $$n/(n - k)$$
- where
- $$n$$
- is the number of observations and
- $$k$$
- the number of estimated parameters.
- ... arguments passed to the `estfun` function.

Details

For some theoretical background along with implementation details see Zeileis (2006).

Value

- A
- $$k \times k$$
- matrix corresponding containing the scaled cross products of the empirical estimating functions.

y <- rnorm(10)
fm <- lm(y ~ x)

meat(fm)
meatHC(fm, type = "HC")
meatHAC(fm)
```

NeweyWest

*Newey-West HAC Covariance Matrix Estimation***Description**

A set of functions implementing the Newey & West (1987, 1994) heteroskedasticity and autocorrelation consistent (HAC) covariance matrix estimators.

Usage

```
NeweyWest(x, lag = NULL, order.by = NULL, prewhite = TRUE, adjust = FALSE,
  diagnostics = FALSE, sandwich = TRUE, ar.method = "ols", data = list(),
  verbose = FALSE)
```

```
bwNeweyWest(x, order.by = NULL, kernel = c("Bartlett", "Parzen",
  "Quadratic Spectral", "Truncated", "Tukey-Hanning"), weights = NULL,
  prewhite = 1, ar.method = "ols", data = list(), ...)
```

Arguments

x	a fitted model object.
lag	integer specifying the maximum lag with positive weight for the Newey-West estimator. If set to NULL <code>floor(bwNeweyWest(x, ...))</code> is used.
order.by	Either a vector <code>z</code> or a formula with a single explanatory variable like <code>~ z</code> . The observations in the model are ordered by the size of <code>z</code> . If set to NULL (the default) the observations are assumed to be ordered (e.g., a time series).
prewhite	logical or integer. Should the estimating functions be prewhitened? If TRUE or greater than 0 a VAR model of order <code>as.integer(prewhite)</code> is fitted via <code>ar</code> with method "ols" and <code>demean = FALSE</code> . The default is to use VAR(1) prewhitening.
kernel	a character specifying the kernel used. All kernels used are described in Andrews (1991). <code>bwNeweyWest</code> can only compute bandwidths for "Bartlett", "Parzen" and "Quadratic Spectral".
adjust	logical. Should a finite sample adjustment be made? This amounts to multiplication with $n/(n - k)$ where n is the number of observations and k the number of estimated parameters.
diagnostics	logical. Should additional model diagnostics be returned? See <code>vcovHAC</code> for details.
sandwich	logical. Should the sandwich estimator be computed? If set to FALSE only the middle matrix is returned.
ar.method	character. The method argument passed to <code>ar</code> for prewhitening (only, not for bandwidth selection).
data	an optional data frame containing the variables in the <code>order.by</code> model. By default the variables are taken from the environment which the function is called from.

verbose	logical. Should the lag truncation parameter used be printed?
weights	numeric. A vector of weights used for weighting the estimated coefficients of the approximation model (as specified by approx). By default all weights are 1 except that for the intercept term (if there is more than one variable).
...	currently not used.

Details

NeweyWest is a convenience interface to `vcovHAC` using Bartlett kernel weights as described in Newey & West (1987, 1994). The automatic bandwidth selection procedure described in Newey & West (1994) is used as the default and can also be supplied to `kernHAC` for the Parzen and quadratic spectral kernel. It is implemented in `bwNeweyWest` which does not truncate its results - if the results for the Parzen and Bartlett kernels should be truncated, this has to be applied afterwards. For Bartlett weights this is implemented in `NeweyWest`.

To obtain the estimator described in Newey & West (1987), prewhitening has to be suppressed.

Value

`NeweyWest` returns the same type of object as `vcovHAC` which is typically just the covariance matrix.

`bwNeweyWest` returns the selected bandwidth parameter.

```

Description

Constructing sandwich covariance matrix estimators by multiplying bread and meat matrices.

Usage

```
sandwich(x, bread. = bread, meat. = meat, ...)
```

Arguments

x	a fitted model object.
bread.	either a bread matrix or a function for computing this via <code>bread.(x)</code> .
meat.	either a bread matrix or a function for computing this via <code>meat.(x, ...)</code> .
...	arguments passed to the meat function.

Details

`sandwich` is a simple convenience function that takes a bread matrix (i.e., estimator of the expectation of the negative derivative of the estimating functions) and a meat matrix (i.e., estimator of the variance of the estimating functions) and multiplies them to a sandwich with meat between two slices of bread. By default `bread` and `meat` are called.

Some theoretical background along with implementation details is given in Zeileis (2006).

Value

A matrix containing the sandwich covariance matrix estimate. Typically, this should be an $k \times k$ matrix corresponding to k parameters.

References

Zeileis A (2006), Object-Oriented Computation of Sandwich Estimators. *Journal of Statistical Software*, **16**(9), 1–16. URL <http://www.jstatsoft.org/v16/i09/>.

```

vcovHAC	<i>Heteroskedasticity and Autocorrelation Consistent (HAC) Covariance Matrix Estimation</i>
---------	---

Description

Heteroskedasticity and autocorrelation consistent (HAC) estimation of the covariance matrix of the coefficient estimates in a (generalized) linear regression model.

Usage

```
vcovHAC(x, ...)

## Default S3 method:
vcovHAC(x, order.by = NULL, prewhite = FALSE, weights = weightsAndrews,
        adjust = TRUE, diagnostics = FALSE, sandwich = TRUE, ar.method = "ols",
        data = list(), ...)

meatHAC(x, order.by = NULL, prewhite = FALSE, weights = weightsAndrews,
        adjust = TRUE, diagnostics = FALSE, ar.method = "ols", data = list())
```

Arguments

<code>x</code>	a fitted model object.
<code>order.by</code>	Either a vector <code>z</code> or a formula with a single explanatory variable like <code>~ z</code> . The observations in the model are ordered by the size of <code>z</code> . If set to <code>NULL</code> (the default) the observations are assumed to be ordered (e.g., a time series).
<code>prewhite</code>	logical or integer. Should the estimating functions be prewhitened? If <code>TRUE</code> or greater than 0 a VAR model of order <code>as.integer(prewhite)</code> is fitted via <code>ar</code> with method <code>"ols"</code> and <code>demean = FALSE</code> .
<code>weights</code>	Either a vector of weights for the autocovariances or a function to compute these weights based on <code>x</code> , <code>order.by</code> , <code>prewhite</code> , <code>ar.method</code> and <code>data</code> . If <code>weights</code> is a function it has to take these arguments. See also details.
<code>adjust</code>	logical. Should a finite sample adjustment be made? This amounts to multiplication with $n/(n - k)$ where n is the number of observations and k the number of estimated parameters.
<code>diagnostics</code>	logical. Should additional model diagnostics be returned? See below for details.
<code>sandwich</code>	logical. Should the sandwich estimator be computed? If set to <code>FALSE</code> only the meat matrix is returned.
<code>ar.method</code>	character. The method argument passed to <code>ar</code> for prewhitening.
<code>data</code>	an optional data frame containing the variables in the <code>order.by</code> model. By default the variables are taken from the environment which <code>vcovHAC</code> is called from.
<code>...</code>	arguments passed to <code>sandwich</code> .

Details

The function `meatHAC` is the real work horse for estimating the meat of HAC sandwich estimators – the default `vcovHAC` method is a wrapper calling `sandwich` and `bread`. See Zeileis (2006) for more implementation details. The theoretical background, exemplified for the linear regression model, is described in Zeileis (2004).

Both functions construct weighted information sandwich variance estimators for parametric models fitted to time series data. These are basically constructed from weighted sums of autocovariances of the estimating functions (as extracted by `estfun`). The crucial step is the specification of weights: the user can either supply `vcovHAC` with some vector of weights or with a function that computes these weights adaptively (based on the arguments `x`, `order.by`, `prewhite` and `data`). Two functions for adaptively choosing weights are implemented in `weightsAndrews` implementing the results of Andrews (1991) and in `weightsLumley` implementing the results of Lumley (1999). The functions `kernHAC` and `weave` respectively are to more convenient interfaces for `vcovHAC` with these functions.

Prewhitening based on VAR approximations is described as suggested in Andrews & Monahan (1992).

The covariance matrix estimators have been improved by the addition of a bias correction and an approximate denominator degrees of freedom for test and confidence interval construction. See Lumley & Heagerty (1999) for details.

Value

A matrix containing the covariance matrix estimate. If `diagnostics` was set to `TRUE` this has an attribute "diagnostics" which is a list with

<code>bias.correction</code>	multiplicative bias correction
<code>df</code>	Approximate denominator degrees of freedom

vcovHC

*Heteroskedasticity-Consistent Covariance Matrix Estimation***Description**

Heteroskedasticity-consistent estimation of the covariance matrix of the coefficient estimates in regression models.

Usage

```
vcovHC(x, ...)

## Default S3 method:
vcovHC(x,
  type = c("HC3", "const", "HC", "HC0", "HC1", "HC2", "HC4", "HC4m", "HC5"),
  omega = NULL, sandwich = TRUE, ...)

meatHC(x, type = , omega = NULL)
```

Arguments

x	a fitted model object.
type	a character string specifying the estimation type. For details see below.
omega	a vector or a function depending on the arguments residuals (the working residuals of the model), diaghat (the diagonal of the corresponding hat matrix) and df (the residual degrees of freedom). For details see below.
sandwich	logical. Should the sandwich estimator be computed? If set to FALSE only the meat matrix is returned.
...	arguments passed to sandwich .

Details

The function `meatHC` is the real work horse for estimating the meat of HC sandwich estimators – the default `vcovHC` method is a wrapper calling [sandwich](#) and [bread](#). See Zeileis (2006) for more implementation details. The theoretical background, exemplified for the linear regression model, is described below and in Zeileis (2004). Analogous formulas are employed for other types of models.

When `type = "const"` constant variances are assumed and `vcovHC` gives the usual estimate of the covariance matrix of the coefficient estimates:

$$\hat{\sigma}^2(X^\top X)^{-1}$$

All other methods do not assume constant variances and are suitable in case of heteroskedasticity. "HC" (or equivalently "HC0") gives White's estimator, the other estimators are refinements of this. They are all of form

$$(X^\top X)^{-1}X^\top \Omega X(X^\top X)^{-1}$$

and differ in the choice of Omega. This is in all cases a diagonal matrix whose elements can be either supplied as a vector omega or as a function omega of the residuals, the diagonal elements of the hat matrix and the residual degrees of freedom. For White's estimator

```
omega <- function(residuals, diaphat, df) residuals^2
```

Instead of specifying the diagonal omega or a function for estimating it, the type argument can be used to specify the HC0 to HC5 estimators. If omega is used, type is ignored.

Long & Ervin (2000) conduct a simulation study of HC estimators (HC0 to HC3) in the linear regression model, recommending to use HC3 which is thus the default in vcovHC. Cribari-Neto (2004), Cribari-Neto, Souza, & Vasconcellos (2007), and Cribari-Neto & Da Silva (2011), respectively, suggest the HC4, HC5, and modified HC4m type estimators. All of them are tailored to take into account the effect of leverage points in the design matrix. For more details see the references.

Value

A matrix containing the covariance matrix estimate.

sigma2 <- sum(residuals(lm(y ~ x))^2)/98
sigma2 * solve(crossprod(cbind(1, x)))
```

vcovOPG

Outer Product of Gradients Covariance Matrix Estimation

Description

Outer product of gradients estimation for the covariance matrix of the coefficient estimates in regression models.

Usage

```
vcovOPG(x, adjust = FALSE, ...)
```

Arguments

<code>x</code>	a fitted model object.
<code>adjust</code>	logical. Should a finite sample adjustment be made? This amounts to multiplication with
	$n/(n - k)$
	where
	n
	is the number of observations and
	k
	the number of estimated parameters.
<code>...</code>	arguments passed to the <code>estfun</code> function.

Details

In correctly specified models, the “meat” matrix (cross product of estimating functions, see [meat](#)) and the inverse of the “bread” matrix (inverse of the derivative of the estimating functions, see [bread](#)) are equal and correspond to the Fisher information matrix. Typically, an empirical version of the bread is used for estimation of the information but alternatively it is also possible to use the meat. This method is also known as the outer product of gradients (OPG) estimator (Cameron & Trivedi 2005).

Using the **sandwich** infrastructure, the OPG estimator could easily be computed via `solve(meat(obj))` (modulo scaling). To employ numerically more stable implementation of the inversion, this simple convenience function can be used: `vcovOPG(obj)`.

Note that this only works if the `estfun()` method computes the maximum likelihood scores (and not a scaled version such as least squares scores for “lm” objects).

Value

A matrix containing the covariance matrix estimate.

fm <- glm(y ~ x, family = poisson)
vcov(fm)
vcovOPG(fm)
```

Description

A set of functions implementing a class of kernel-based heteroskedasticity and autocorrelation consistent (HAC) covariance matrix estimators as introduced by Andrews (1991).

Usage

```
kernHAC(x, order.by = NULL, prewhite = 1, bw = bwAndrews,
        kernel = c("Quadratic Spectral", "Truncated", "Bartlett", "Parzen", "Tukey-Hanning"),
        approx = c("AR(1)", "ARMA(1,1)"), adjust = TRUE, diagnostics = FALSE,
        sandwich = TRUE, ar.method = "ols", tol = 1e-7, data = list(), verbose = FALSE, ...)
```

```
weightsAndrews(x, order.by = NULL, bw = bwAndrews,
               kernel = c("Quadratic Spectral", "Truncated", "Bartlett", "Parzen", "Tukey-Hanning"),
               prewhite = 1, ar.method = "ols", tol = 1e-7, data = list(), verbose = FALSE, ...)
```

```
bwAndrews(x, order.by = NULL, kernel = c("Quadratic Spectral", "Truncated",
    "Bartlett", "Parzen", "Tukey-Hanning"), approx = c("AR(1)", "ARMA(1,1)"),
    weights = NULL, prewhite = 1, ar.method = "ols", data = list(), ...)
```

Arguments

x	a fitted model object.
order.by	Either a vector z or a formula with a single explanatory variable like ~ z. The observations in the model are ordered by the size of z. If set to NULL (the default) the observations are assumed to be ordered (e.g., a time series).
prewhite	logical or integer. Should the estimating functions be prewhitened? If TRUE or greater than 0 a VAR model of order as.integer(prewhite) is fitted via ar with method "ols" and demean = FALSE. The default is to use VAR(1) prewhitening.
bw	numeric or a function. The bandwidth of the kernel (corresponds to the truncation lag). If set to to a function (the default is bwAndrews) it is adaptively chosen.
kernel	a character specifying the kernel used. All kernels used are described in Andrews (1991).
approx	a character specifying the approximation method if the bandwidth bw has to be chosen by bwAndrews.
adjust	logical. Should a finite sample adjustment be made? This amounts to multiplication with $n/(n - k)$ where n is the number of observations and k the number of estimated parameters.
diagnostics	logical. Should additional model diagnostics be returned? See vcovHAC for details.
sandwich	logical. Should the sandwich estimator be computed? If set to FALSE only the middle matrix is returned.
ar.method	character. The method argument passed to ar for prewhitening (only, not for bandwidth selection).
tol	numeric. Weights that exceed tol are used for computing the covariance matrix, all other weights are treated as 0.
data	an optional data frame containing the variables in the order.by model. By default the variables are taken from the environment which the function is called from.

verbose	logical. Should the bandwidth parameter used be printed?
...	further arguments passed to bwAndrews.
weights	numeric. A vector of weights used for weighting the estimated coefficients of the approximation model (as specified by approx). By default all weights are 1 except that for the intercept term (if there is more than one variable).

Details

kernHAC is a convenience interface to [vcovHAC](#) using weightsAndrews: first a weights function is defined and then vcovHAC is called.

The kernel weights underlying weightsAndrews are directly accessible via the function [kweights](#) and require the specification of the bandwidth parameter bw. If this is not specified it can be chosen adaptively by the function bwAndrews (except for the "Truncated" kernel). The automatic bandwidth selection is based on an approximation of the estimating functions by either AR(1) or ARMA(1,1) processes. To aggregate the estimated parameters from these approximations a weighted sum is used. The weights in this aggregation are by default all equal to 1 except that corresponding to the intercept term which is set to 0 (unless there is no other variable in the model) making the covariance matrix scale invariant.

Further details can be found in Andrews (1991).

The estimator of Newey & West (1987) is a special case of the class of estimators introduced by Andrews (1991). It can be obtained using the "Bartlett" kernel and setting bw to lag + 1. A convenience interface is provided in [NeweyWest](#).

Value

kernHAC returns the same type of object as [vcovHAC](#) which is typically just the covariance matrix.

weightsAndrews returns a vector of weights.

bwAndrews returns the selected bandwidth parameter.

weightsLumley

Weighted Empirical Adaptive Variance Estimation

Description

A set of functions implementing a class of kernel-based heteroskedasticity and autocorrelation consistent (HAC) covariance matrix estimators as introduced by Andrews (1991).

Usage

```

weave(x, order.by = NULL, prewhite = FALSE, C = NULL,
      method = c("truncate", "smooth"), acf = isoacf, adjust = FALSE,
      diagnostics = FALSE, sandwich = TRUE, tol = 1e-7, data = list(), ...)

weightsLumley(x, order.by = NULL, C = NULL,
              method = c("truncate", "smooth"), acf = isoacf, tol = 1e-7, data = list(), ...)

```

Arguments

x	a fitted model object.
order.by	Either a vector z or a formula with a single explanatory variable like ~ z. The observations in the model are ordered by the size of z. If set to NULL (the default) the observations are assumed to be ordered (e.g., a time series).
prewhite	logical or integer. Should the estimating functions be prewhitened? If TRUE or greater than 0 a VAR model of order as.integer(prewhite) is fitted via ar with method "ols" and demean = FALSE.

C	numeric. The cutoff constant C is by default 4 for method "truncate" and 1 for method "smooth".
method	a character specifying the method used, see details.
acf	a function that computes the autocorrelation function of a vector, by default isoacf is used.
adjust	logical. Should a finite sample adjustment be made? This amounts to multiplication with $n/(n - k)$ where n is the number of observations and k the number of estimated parameters.
diagnostics	logical. Should additional model diagnostics be returned? See vcovHAC for details.
sandwich	logical. Should the sandwich estimator be computed? If set to FALSE only the middle matrix is returned.
tol	numeric. Weights that exceed tol are used for computing the covariance matrix, all other weights are treated as 0.
data	an optional data frame containing the variables in the order .by model. By default the variables are taken from the environment which the function is called from.
...	currently not used.

Details

weave is a convenience interface to [vcovHAC](#) using weightsLumley: first a weights function is defined and then vcovHAC is called.

Both weighting methods are based on some estimate of the autocorrelation function ρ (as computed by acf) of the residuals of the model x . The weights for the "truncate" method are

$$I\{n\rho^2 > C\}$$

and the weights for the "smooth" method are

$$\min\{1, Cn\rho^2\}$$

where n is the number of observations in the model and C is the truncation constant C .

Further details can be found in Lumley & Heagerty (1999).

Value

weave returns the same type of object as [vcovHAC](#) which is typically just the covariance matrix.

weightsLumley returns a vector of weights.
