Alternatively, arguments coerce and replace should be supplied, defining methods to coerce to the superclass and to replace the part corresponding to the superclass. As discussed in the details and other sections below, this form is often less recommended than the corresponding call to setAs, to which it is an alternative.

Argument test allows conditional inheritance, in which the is() result is tested for each object rather than being determined by the class definition. This form is discouraged when it can be avoided; in particular, note that conditional inheritance is not used to select methods for dispatch.

Details

Arranging for a class to inherit from another class is a key tool in programming. In R, there are three basic techniques, the first two providing what is called “simple” inheritance, the preferred form:

1. By the contains argument in a call to setClass. This is and should be the most common mechanism. It arranges that the new class contains all the structure of the existing class, and in particular all the slots with the same class specified. The resulting class extension is defined to be simple, with important implications for method definition (see the section on this topic below).

2. Making class1 a subclass of a virtual class either by a call to setClassUnion to make the subclass a member of a new class union, or by a call to setIs to add a class to an existing class union or as a new subclass of an existing virtual class. In either case, the implication should be that methods defined for the class union or other superclass all work correctly for the subclass. This may depend on some similarity in the structure of the subclasses or simply indicate that the superclass methods are defined in terms of generic functions that apply to all the subclasses. These relationships are also generally simple.

3. Supplying coerce and replace arguments to setAs. R allows arbitrary inheritance relationships, using the same mechanism for defining coerce methods by a call to setAs. The difference between the two is simply that setAs will require a call to as for a conversion to take place, whereas after the call to setIs, objects will be automatically converted to the superclass.

The automatic feature is the dangerous part, mainly because it results in the subclass potentially inheriting methods that do not work. See the section on inheritance below. If the two classes involved do not actually inherit a large collection of methods, as in the first example below, the danger may be relatively slight.

If the superclass inherits methods where the subclass has only a default or remotely inherited method, problems are more likely. In this case, a general recommendation is to use the setAs mechanism instead, unless there is a strong counter reason. Otherwise, be prepared to override some of the methods inherited.

With this caution given, the rest of this section describes what happens when coerce= and replace= arguments are supplied to setIs.
The coerce and replace arguments are functions that define how to coerce a class1 object to class2, and how to replace the part of the subclass object that corresponds to class2. The first of these is a function of one argument which should be from, and the second of two arguments (from, value). For details, see the section on coerce functions below.

When by is specified, the coerce process first coerces to this class and then to class2. It’s unlikely you would use the by argument directly, but it is used in defining cached information about classes.

The value returned (invisibly) by setIs is the revised class definition of class1.

Coerce, replace, and test functions

The coerce argument is a function that turns a class1 object into a class2 object. The replace argument is a function of two arguments that modifies a class1 object (the first argument) to replace the part of it that corresponds to class2 (supplied as value, the second argument). It then returns the modified object as the value of the call. In other words, it acts as a replacement method to implement the expression as(object, class2) <- value.

The easiest way to think of the coerce and replace functions is by thinking of the case that class1 contains class2 in the usual sense, by including the slots of the second class. (To repeat, in this situation you would not call setIs, but the analogy shows what happens when you do.)

The coerce function in this case would just make a class2 object by extracting the corresponding slots from the class1 object. The replace function would replace in the class1 object the slots corresponding to class2, and return the modified object as its value.

For additional discussion of these functions, see the documentation of the setIs function. (Unfortunately, argument def to that function corresponds to argument coerce here.)

The inheritance relationship can also be conditional, if a function is supplied as the test argument. This should be a function of one argument that returns TRUE or FALSE according to whether the object supplied satisfies the relation is(object, class2). Conditional relations between classes are discouraged in general because they require a per-object calculation to determine their validity. They cannot be applied as efficiently as ordinary relations and tend to make the code that uses them harder to interpret. NOTE: conditional inheritance is not used to dispatch methods. Methods for conditional superclasses will not be inherited. Instead, a method for the subclass should be defined that tests the conditional relationship.

Inherited methods

A method written for a particular signature (classes matched to one or more formal arguments to the function) naturally assumes that the objects corresponding to the arguments can be treated as coming from the corresponding classes. The objects will have all the slots and available methods for the classes.

The code that selects and dispatches the methods ensures that this assumption is correct. If the inheritance was “simple”, that is, defined by one or more uses of the contains= argument in a call to setClass, no extra work is generally needed. Classes are inherited from the superclass, with the same definition.

When inheritance is defined by a general call to setIs, extra computations are required. This form of inheritance implies that the subclass does not just contain the slots of the superclass, but instead requires the explicit call to the coerce and/or replace method. To ensure correct computation, the inherited method is supplemented by calls to as before the body of the method is evaluated.

The calls to as generated in this case have the argument strict = FALSE, meaning that extra information can be left in the converted object, so long as it has all the appropriate slots. (It’s this option that allows simple subclass objects to be used without any change.) When you are writing your coerce method, you may want to take advantage of that option.
Methods inherited through non-simple extensions can result in ambiguities or unexpected selections. If `class2` is a specialized class with just a few applicable methods, creating the inheritance relation may have little effect on the behavior of `class1`. But if `class2` is a class with many methods, you may find that you now inherit some undesirable methods for `class1`, in some cases, fail to inherit expected methods. In the second example below, the non-simple inheritance from class "factor" might be assumed to inherit S3 methods via that class. But the S3 class is ambiguous, and in fact is "character" rather than "factor".

For some generic functions, methods inherited by non-simple extensions are either known to be invalid or sufficiently likely to be so that the generic function has been defined to exclude such inheritance. For example `initialize` methods must return an object of the target class; this is straightforward if the extension is simple, because no change is made to the argument object, but is essentially impossible. For this reason, the generic function insists on only simple extensions for inheritance. See the `simpleInheritanceOnly` argument to `setGeneric` for the mechanism. You can use this mechanism when defining new generic functions.

If you get into problems with functions that do allow non-simple inheritance, there are two basic choices. Either back off from the `setIs` call and settle for explicit coercing defined by a call to `setAs`; or, define explicit methods involving `class1` to override the bad inherited methods. The first choice is the safer, when there are serious problems.

See Also

`inherits` is nearly always equivalent to `is`, both for S4 and non-S4 objects, and is somewhat faster. The non-equivalence applies to classes that have conditional superclasses, with a non-trivial test in the relation (not common and discouraged): for these, `is` tests for the relation but `inherits` by definition ignores conditional inheritance for S4 objects.

`selectSuperClasses`(`cl`) has similar semantics as `extends`(`cl`), typically returning subsets of the latter.

Examples

```r
## Two examples of setIs() with coerce= and replace= arguments
## The first one works fairly well, because neither class has many
## inherited methods do be disturbed by the new inheritance

## The second example does NOT work well, because the new superclass,
## "factor", causes methods to be inherited that should not be.

## First example:
## a class definition (see \link{setClass} for class "track")
setClass("trackCurve", contains = "track",
  representation( smooth = "numeric"))

## A class similar to "trackCurve", but with different structure
## allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve",
  representation(x="numeric", y="matrix", smooth="matrix"),
  prototype = structure(list(), x=numeric(), y=matrix(0,0,0),
```
isSealedMethod

Check for a Sealed Method or Class

Description
These functions check for either a method or a class that has been sealed when it was defined, and which therefore cannot be re-defined.

Usage

isSealedMethod(f, signature, fdef, where)
isSealedClass(Class, where)

### Second Example:

#### A class that adds a slot to "character"
setClass("stringsDated", contains = "character",
representation(stamp="POSIXt"))

#### Convert automatically to a factor by explicit coerce
setIs("stringsDated", "factor",
coerce = function(from) factor(from@.Data),
replace = function(from, value) { 
  from@.Data <- as.character(value); from })

ll <- sample(letters, 10, replace = TRUE)
l1 <- new("stringsDated", ll, stamp = Sys.time())

levels(as(l1, "factor"))
levels(l1) # will be NULL---see comment in section on inheritance above.

#### In contrast, a class that simply extends "factor"
#### has no such ambiguities
setClass("factorDated", contains = "factor",
representation(stamp="POSIXt"))

fd <- new("factorDated", factor(ll), stamp = Sys.time())
identical(levels(fd), levels(as(fd, "factor")))
Arguments

- **f**
  The quoted name of the generic function.
- **signature**
  The class names in the method’s signature, as they would be supplied to `setMethod`.
- **fdef**
  Optional, and usually omitted: the generic function definition for `f`.
- **Class**
  The quoted name of the class.
- **where**
  Where to search for the method or class definition. By default, searches from the top environment of the call to `isSealedMethod` or `isSealedClass`, typically the global environment or the namespace of a package containing a call to one of the functions.

Details

In the R implementation of classes and methods, it is possible to seal the definition of either a class or a method. The basic classes (numeric and other types of vectors, matrix and array data) are sealed. So also are the methods for the primitive functions on those data types. The effect is that programmers cannot re-define the meaning of these basic data types and computations. More precisely, for primitive functions that depend on only one data argument, methods cannot be specified for basic classes. For functions (such as the arithmetic operators) that depend on two arguments, methods can be specified if one of those arguments is a basic class, but not if both are.

Programmers can seal other class and method definitions by using the `sealed` argument to `setClass` or `setMethod`.

Value

The functions return `FALSE` if the method or class is not sealed (including the case that it is not defined); `TRUE` if it is.

References

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

Examples

```r
## these are both TRUE
isSealedMethod("+", c("numeric", "character"))
isSealedClass("matrix")

setClass("track",
  representation(x="numeric", y="numeric"))
## but this is FALSE
isSealedClass("track")
## and so is this
isSealedClass("A Name for an undefined Class")
## and so are these, because only one of the two arguments is basic
isSealedMethod("+", c("track", "numeric"))
isSealedMethod("+", c("numeric", "track"))
```
Classes to Represent Unevaluated Language Objects

Description

The virtual class "language" and the specific classes that extend it represent unevaluated objects, as produced for example by the parser or by functions such as quote.

Usage

### each of these classes corresponds to an unevaluated object
### in the S language.
### The class name can appear in method signatures,
### and in a few other contexts (such as some calls to as()).

"("  
""  
"call"  
"for"  
"if"  
"repeat"  
"while"  
"name"  
"

### Each of the classes above extends the virtual class
"language"

Objects from the Class

"language" is a virtual class; no objects may be created from it.

Objects from the other classes can be generated by a call to new(Class, ...), where Class is the quoted class name, and the ...arguments are either empty or a single object that is from this class (or an extension).

Methods

coerce signature(from = "ANY", to = "call"). A method exists for as(object, "call"), calling as.call().

Description

A version of methods lists that has been ‘linearized’ for producing summary information. The actual objects from class "MethodsList" used for method dispatch are defined recursively over the arguments involved.
Objects from the Class

The function `linearizeMlist` converts an ordinary methods list object into the linearized form.

Slots

- `methods`: Object of class "list", the method definitions.
- `arguments`: Object of class "list", the corresponding formal arguments, namely as many of the arguments in the signature of the generic function as are active in the relevant method table.
- `classes`: Object of class "list", the corresponding classes in the signatures.
- `generic`: Object of class "genericFunction": the generic function to which the methods correspond.

Future Note

The current version of `linearizeMlist` does not take advantage of the `MethodDefinition` class, and therefore does more work for less effect than it could. In particular, we may move to redefine both the function and the class to take advantage of the stored signatures. Don’t write code depending precisely on the present form, although all the current information will be obtainable in the future.

See Also

Function `linearizeMlist` for the computation, and class `MethodsList` for the original, recursive form.

LocalReferenceClasses  Localized Objects based on Reference Classes

Description

Local reference classes are modified ReferenceClasses that isolate the objects to the local frame. Therefore, they do not propagate changes back to the calling environment. At the same time, they use the reference field semantics locally, avoiding the automatic duplication applied to standard R objects.

The current implementation has no special construction. To create a local reference class, call `setRefClass()` with a contains= argument that includes "localRefClass". See the example below.

Local reference classes operate essentially as do regular, functional classes in R; that is, changes are made by assignment and take place in the local frame. The essential difference is that replacement operations (like the change to the twiddle field in the example) do not cause duplication of the entire object, as would be the case for a formal class or for data with attributes or in a named list. The purpose is to allow large objects in some fields that are not changed along with potentially frequent changes to other fields, but without copying the large fields.

Usage

```r
setRefClass(Class, fields = , contains = c("localRefClass",....),
            methods =, where =, ...)```

Details

Localization of objects is only partially automated in the current implementation. Replacement expressions using the $\leftarrow$ operator are safe.

However, if reference methods for the class themselves modify fields, using $\leftarrow$, for example, then one must ensure that the object is local to the relevant frame before any such method is called. Otherwise, standard reference class behavior still prevails.

There are two ways to ensure locality. The direct way is to invoke the special method `x$ensureLocal()` on the object. The other way is to modify a field explicitly by `x$field $\leftarrow$ ...`. It's only necessary that one or the other of these happens once for each object, in order to trigger the shallow copy that provides locality for the references. In the example below, we show both mechanisms.

However it's done, localization must occur before any methods make changes. (Eventually, some use of code tools should at least largely automate this process, although it may be difficult to guarantee success under arbitrary circumstances.)

Author(s)

John Chambers

Examples

```r
## class "myIter" has a BigData field for the real (big) data
## and a "twiddle" field for some parameters that it twiddles
## ( for some reason)
myIter <- setRefClass("myIter", contains = "localRefClass",
  fields = list(BigData = "numeric", twiddle = "numeric"))

tw <- rnorm(3)
x1 <- myIter(BigData = rnorm(1000), twiddle = tw) # OK, not REALLY big
twiddler <- function(x, n) {
  x$ensureLocal() # see the Details. Not really needed in this example
  for(i in seq(length = n)) {
    x$twiddle $\leftarrow$ x$twiddle + rnorm(length(x$twiddle))
    ## then do something ....
    ## Snooping in gdb, etc will show that x$BigData is not copied
  }
  return(x)
}

x2 <- twiddler(x1, 10)

stopifnot(identical(x1$twiddle, tw), !identical(x1$twiddle, x2$twiddle))
```

---

Create a Class Definition
Description

Constructs an object of class `classRepresentation` to describe a particular class. Mostly a utility function, but you can call it to create a class definition without assigning it, as `setClass` would do.

Usage

```r
makeClassRepresentation(name, slots=list(), superClasses=character(),
  prototype=NULL, package, validity, access,
  version, sealed, virtual=NA, where)
```

Arguments

- **name**: character string name for the class
- **slots**: named list of slot classes as would be supplied to `setClass`, but *without* the unnamed arguments for `superClasses` if any.
- **superClasses**: what classes does this class extend
- **prototype**: an object providing the default data for the class, e.g., the result of a call to `prototype`.
- **package**: The character string name for the package in which the class will be stored; see `getPackageName`.
- **validity**: Optional validity method. See `validObject`, and the discussion of validity methods in the reference.
- **access**: Access information. Not currently used.
- **version**: Optional version key for version control. Currently generated, but not used.
- **sealed**: Is the class sealed? See `setClass`.
- **virtual**: Is this known to be a virtual class?
- **where**: The environment from which to look for class definitions needed (e.g., for slots or superclasses). See the discussion of this argument under `GenericFunctions`.

`setClass`
Create a Skeleton File for a New Method

Description

This function writes a source file containing a call to setMethod to define a method for the generic function and signature supplied. By default the method definition is in line in the call, but can be made an external (previously assigned) function.

Usage

method.skeleton(generic, signature, file, external = FALSE, where)

Arguments

generic the character string name of the generic function, or the generic function itself. In the first case, the function need not currently be a generic, as it would not for the resulting call to setMethod.

signature the method signature, as it would be given to setMethod.

file a character string name for the output file, or a writable connection. By default the generic function name and the classes in the signature are concatenated, with separating underscore characters. The file name should normally end in ".R". To write multiple method skeletons to one file, open the file connection first and then pass it to method.skeleton() in multiple calls.

external flag to control whether the function definition for the method should be a separate external object assigned in the source file, or included in line in the call to setMethod. If supplied as a character string, this will be used as the name for the external function; by default the name concatenates the generic and signature names, with separating underscores.

where The environment in which to look for the function; by default, the top-level environment of the call to method.skeleton.

Value

The file argument, invisibly, but the function is used for its side effect.

See Also

setMethod, package.skeleton

Examples

setClass("track", representation(x="numeric", y="numeric"))
method.skeleton("show", "track")## writes show_track.R
method.skeleton("Ops", c("track", "track"))## writes "Ops_track_track.R"

## write multiple method skeletons to one file
con <- file("./Math_track.R", "w")
method.skeleton("Math", "track", con)
method.skeleton("exp", "track", con)
method.skeleton("log", "track", con)
Classes to Represent Method Definitions

Description

These classes extend the basic class "function" when functions are to be stored and used as method definitions.

Details

Method definition objects are functions with additional information defining how the function is being used as a method. The target slot is the class signature for which the method will be dispatched, and the defined slot the signature for which the method was originally specified (that is, the one that appeared in some call to setMethod).

Objects from the Class

The action of setting a method by a call to setMethod creates an object of this class. It's unwise to create them directly.

The class "SealedMethodDefinition" is created by a call to setMethod with argument sealed = TRUE. It has the same representation as "MethodDefinition".

Slots

.Data: Object of class "function"; the data part of the definition.
target: Object of class "signature"; the signature for which the method was wanted.
defined: Object of class "signature"; the signature for which a method was found. If the method was inherited, this will not be identical to target.
generic: Object of class "character"; the function for which the method was created.

Extends

Class "function", from data part.
Class "PossibleMethod", directly.
Class "OptionalMethods", by class "function".

See Also

class MethodsList for the objects defining sets of methods associated with a particular generic function. The individual method definitions stored in these objects are from class MethodDefinition, or an extension. Class MethodWithNext for an extension used by callNextMethod.
Methods

General Information on Methods

Description

This documentation section covers some general topics on how methods work and how the methods package interacts with the rest of R. The information is usually not needed to get started with methods and classes, but may be helpful for moderately ambitious projects, or when something doesn’t work as expected.

The section “How Methods Work” describes the underlying mechanism; “S3 Methods and Generic Functions” gives the rules applied when S4 classes and methods interact with older S3 methods; “Method Selection and Dispatch” provides more details on how class definitions determine which methods are used; “Generic Functions” discusses generic functions as objects. For additional information specifically about class definitions, see Classes.

How Methods Work

A generic function has associated with it a collection of other functions (the methods), all of which have the same formal arguments as the generic. See the “Generic Functions” section below for more on generic functions themselves.

Each R package will include methods metadata objects corresponding to each generic function for which methods have been defined in that package. When the package is loaded into an R session, the methods for each generic function are cached, that is, stored in the environment of the generic function along with the methods from previously loaded packages. This merged table of methods is used to dispatch or select methods from the generic, using class inheritance and possibly group generic functions (see GroupGenericFunctions) to find an applicable method. See the “Method Selection and Dispatch” section below. The caching computations ensure that only one version of each generic function is visible globally; although different attached packages may contain a copy of the generic function, these behave identically with respect to method selection. In contrast, it is possible for the same function name to refer to more than one generic function, when these have different package slots. In the latter case, R considers the functions unrelated: A generic function is defined by the combination of name and package. See the “Generic Functions” section below.

The methods for a generic are stored according to the corresponding signature in the call to setMethod that defined the method. The signature associates one class name with each of a subset of the formal arguments to the generic function. Which formal arguments are available, and the order in which they appear, are determined by the "signature" slot of the generic function itself. By default, the signature of the generic consists of all the formal arguments except . . . , in the order they appear in the function definition.

Trailing arguments in the signature of the generic will be inactive if no method has yet been specified that included those arguments in its signature. Inactive arguments are not needed or used in labeling the cached methods. (The distinction does not change which methods are dispatched, but ignoring inactive arguments improves the efficiency of dispatch.)

All arguments in the signature of the generic function will be evaluated when the function is called, rather than using the traditional lazy evaluation rules of S. Therefore, it’s important to exclude from the signature any arguments that need to be dealt with symbolically (such as the first argument to function substitute). Note that only actual arguments are evaluated, not default expressions. A missing argument enters into the method selection as class "missing".

The cached methods are stored in an environment object. The names used for assignment are a concatenation of the class names for the active arguments in the method signature.
Methods for S3 Generic Functions

S4 methods may be wanted for functions that also have S3 methods, corresponding to classes for
the first formal argument of an S3 generic function–either a regular R function in which there is a
call to the S3 dispatch function, \texttt{UseMethod}, or one of a fixed set of primitive functions, which are
not true functions but go directly to C code. In either case S3 method dispatch looks at the class of
the first argument or the class of either argument in a call to one of the primitive binary operators.
S3 methods are ordinary functions with the same arguments as the generic function (for primitives
the formal arguments are not actually part of the object, but are simulated when the object is printed
or viewed by \texttt{args}). The “signature” of an S3 method is identified by the name to which the
method is assigned, composed of the name of the generic function, followed by ".\).

To implement a method for one of these functions corresponding to S4 classes, there are two pos-
sibilities: either an S4 method or an S3 method with the S4 class name. The S3 method is only
possible if the intended signature has the first argument and nothing else. In this case, the recom-
mended approach is to define the S3 method and also supply the identical function as the definition
of the S4 method. If the S3 generic function was \texttt{f3(x, \ldots)} and the S4 class for the new method
was "myClass":

\begin{verbatim}
f3.myClass <- function(x, ...) { ..... }
setMethod("f3", "myClass", f3.myClass)
\end{verbatim}

The reasons for defining both S3 and S4 methods are as follows:

1. An S4 method alone will not be seen if the S3 generic function is called directly. However,
   primitive functions and operators are exceptions: The internal C code will look for S4 meth-
   ods if and only if the object is an S4 object. In the examples, the method for `\[` for class
   "myFrame" will always be called for objects of this class.
   For the same reason, an S4 method defined for an S3 class will not be called from internal
code for a non-S4 object. (See the example for function \texttt{Math} and class "data.frame" in the
examples.)

2. An S3 method alone will not be called if there is any eligible non-default S4 method. (See the
   example for function \texttt{f3} and class "classA" in the examples.)

Details of the selection computations are given below.

When an S4 method is defined for an existing function that is not an S4 generic function (whether or
not the existing function is an S3 generic), an S4 generic function will be created corresponding to
the existing function and the package in which it is found (more precisely, according to the implicit
generic function either specified or inferred from the ordinary function; see \texttt{implicitGeneric}). A
message is printed after the initial call to \texttt{setMethod}; this is not an error, just a reminder that you
have created the generic. Creating the generic explicitly by the call

\begin{verbatim}
setGeneric("f3")
\end{verbatim}

avoids the message, but has the same effect. The existing function becomes the default method for
the S4 generic function. Primitive functions work the same way, but the S4 generic function is not
explicitly created (as discussed below).

S4 and S3 method selection are designed to follow compatible rules of inheritance, as far as possible.
S3 classes can be used for any S4 method selection, provided that the S3 classes have been registered
by a call to \texttt{setOldClass}, with that call specifying the correct S3 inheritance pattern. S4 classes can
be used for any S3 method selection; when an S4 object is detected, S3 method selection uses the
contents of \texttt{extends(class(x))} as the equivalent of the S3 inheritance (the inheritance is cached
after the first call).

An existing S3 method may not behave as desired for an S4 subclass, in which case utilities such as
\texttt{asS3} and \texttt{S3Part} may be useful. If the S3 method fails on the S4 object, \texttt{asS3(x)} may be
passed instead; if the object returned by the S3 method needs to be incorporated in the S4 object, the replacement function for S3Part may be useful, as in the method for class "myFrame" in the examples.

Here are details explaining the reasons for defining both S3 and S4 methods. Calls still accessing the S3 generic function directly will not see S4 methods, except in the case of primitive functions. This means that calls to the generic function from namespaces that import the S3 generic but not the S4 version will only see S3 methods. On the other hand, S3 methods will only be selected from the S4 generic function as part of its default ("ANY") method. If there are inherited S4 non-default methods, these will be chosen in preference to any S3 method.

S3 generic functions implemented as primitive functions (including binary operators) are an exception to recognizing only S3 methods. These functions dispatch both S4 and S3 methods from the internal C code. There is no explicit generic function, either S3 or S4. The internal code looks for S4 methods if the first argument, or either of the arguments in the case of a binary operator, is an S4 object. If no S4 method is found, a search is made for an S3 method.

S4 methods can be defined for an S3 generic function and an S3 class, but if the function is a primitive, such methods will not be selected if the object in question is not an S4 object. In the examples below, for instance, an S4 method for signature "data.frame" for function f3() would be called for the S3 object df1. A similar S4 method for primitive function `\` would be ignored for that object, but would be called for the S4 object mydf1 that inherits from "data.frame". Defining both an S3 and S4 method removes this inconsistency.

**Method Selection and Dispatch: Details**

When a call to a generic function is evaluated, a method is selected corresponding to the classes of the actual arguments in the signature. First, the cached methods table is searched for an exact match; that is, a method stored under the signature defined by the string value of class(x) for each non-missing argument, and "missing" for each missing argument. If no method is found directly for the actual arguments in a call to a generic function, an attempt is made to match the available methods to the arguments by using the superclass information about the actual classes.

Each class definition may include a list of one or more superclasses of the new class. The simplest and most common specification is by the contains= argument in the call to setClass. Each class named in this argument is a superclass of the new class. Two additional mechanisms for defining superclasses exist. A call to setClassUnion creates a union class that is a superclass of each of the members of the union. A call to setIs can create an inheritance relationship that is not the simple one of containing the superclass representation in the new class. Arguments coerce and replace supply methods to convert to the superclass and to replace the part corresponding to the superclass. (In addition, a test= argument allows conditional inheritance; conditional inheritance is not recommended and is not used in method selection.) All three mechanisms are treated equivalently for purposes of method selection: they define the direct superclasses of a particular class. For more details on the mechanisms, see Classes.

The direct superclasses themselves may have superclasses, defined by any of the same mechanisms, and similarly through further generations. Putting all this information together produces the full list of superclasses for this class. The superclass list is included in the definition of the class that is cached during the R session. Each element of the list describes the nature of the relationship (see SClassExtension for details). Included in the element is a distance slot containing the path length for the relationship: 1 for direct superclasses (regardless of which mechanism defined them), then 2 for the direct superclasses of those classes, and so on. In addition, any class implicitly has class "ANY" as a superclass. The distance to "ANY" is treated as larger than the distance to any actual class. The special class "missing" corresponding to missing arguments has only "ANY" as a superclass, while "ANY" has no superclasses.
Methods

When a class definition is created or modified, the superclasses are ordered, first by a stable sort of the all superclasses by distance. If the set of superclasses has duplicates (that is, if some class is inherited through more than one relationship), these are removed, if possible, so that the list of superclasses is consistent with the superclasses of all direct superclasses. See the reference on inheritance for details.

The information about superclasses is summarized when a class definition is printed.

When a method is to be selected by inheritance, a search is made in the table for all methods directly corresponding to a combination of either the direct class or one of its superclasses, for each argument in the active signature. For an example, suppose there is only one argument in the signature and that the class of the corresponding object was "dgeMatrix" (from the recommended package Matrix). This class has two direct superclasses and through these 4 additional superclasses. Method selection finds all the methods in the table of directly specified methods labeled by one of these classes, or by "ANY".

When there are multiple arguments in the signature, each argument will generate a similar list of inherited classes. The possible matches are now all the combinations of classes from each argument (think of the function outer generating an array of all possible combinations). The search now finds all the methods matching any of this combination of classes. For each argument, the position in the list of superclasses of that argument’s class defines which method or methods (if the same class appears more than once) match best. When there is only one argument, the best match is unambiguous. With more than one argument, there may be zero or one match that is among the best matches for all arguments.

If there is no best match, the selection is ambiguous and a message is printed noting which method was selected (the first method lexicographically in the ordering) and what other methods could have been selected. Since the ambiguity is usually nothing the end user could control, this is not a warning. Package authors should examine their package for possible ambiguous inheritance by calling testInheritedMethods.

When the inherited method has been selected, the selection is cached in the generic function so that future calls with the same class will not require repeating the search. Cached inherited selections are not themselves used in future inheritance searches, since that could result in invalid selections. If you want inheritance computations to be done again (for example, because a newly loaded package has a more direct method than one that has already been used in this session), call resetGeneric. Because classes and methods involving them tend to come from the same package, the current implementation does not reset all generics every time a new package is loaded.

Besides being initiated through calls to the generic function, method selection can be done explicitly by calling the function selectMethod.

Once a method has been selected, the evaluator creates a new context in which a call to the method is evaluated. The context is initialized with the arguments from the call to the generic function. These arguments are not rematched. All the arguments in the signature of the generic will have been evaluated (including any that are currently inactive); arguments that are not in the signature will obey the usual lazy evaluation rules of the language. If an argument was missing in the call, its default expression if any will not have been evaluated, since method dispatch always uses class missing for such arguments.

A call to a generic function therefore has two contexts: one for the function and a second for the method. The argument objects will be copied to the second context, but not any local objects created in a nonstandard generic function. The other important distinction is that the parent ("enclosing") environment of the second context is the environment of the method as a function, so that all R programming techniques using such environments apply to method definitions as ordinary functions.

For further discussion of method selection and dispatch, see the first reference.
Generic Functions

In principle, a generic function could be any function that evaluates a call to `standardGeneric()`, the internal function that selects a method and evaluates a call to the selected method. In practice, generic functions are special objects that in addition to being from a subclass of class "function" also extend the class `genericFunction`. Such objects have slots to define information needed to deal with their methods. They also have specialized environments, containing the tables used in method selection.

The slots "generic" and "package" in the object are the character string names of the generic function itself and of the package from which the function is defined. As with classes, generic functions are uniquely defined in R by the combination of the two names. There can be generic functions of the same name associated with different packages (although inevitably keeping such functions cleanly distinguished is not always easy). On the other hand, R will enforce that only one definition of a generic function can be associated with a particular combination of function and package name, in the current session or other active version of R.

Tables of methods for a particular generic function, in this sense, will often be spread over several other packages. The total set of methods for a given generic function may change during a session, as additional packages are loaded. Each table must be consistent in the signature assumed for the generic function.

R distinguishes standard and nonstandard generic functions, with the former having a function body that does nothing but dispatch a method. For the most part, the distinction is just one of simplicity: knowing that a generic function only dispatches a method call allows some efficiencies and also removes some uncertainties.

In most cases, the generic function is the visible function corresponding to that name, in the corresponding package. There are two exceptions, implicit generic functions and the special computations required to deal with R’s primitive functions. Packages can contain a table of implicit generic versions of functions in the package, if the package wishes to leave a function non-generic but to constrain what the function would be like if it were generic. Such implicit generic functions are created during the installation of the package, essentially by defining the generic function and possibly methods for it, and then reverting the function to its non-generic form. (See `implicitGeneric` for how this is done.) The mechanism is mainly used for functions in the older packages in R, which may prefer to ignore S4 methods. Even in this case, the actual mechanism is only needed if something special has to be specified. All functions have a corresponding implicit generic version defined automatically (an implicit, implicit generic function one might say). This function is a standard generic with the same arguments as the non-generic function, with the non-generic version as the default (and only) method, and with the generic signature being all the formal arguments except ....

The implicit generic mechanism is needed only to override some aspect of the default definition. One reason to do so would be to remove some arguments from the signature. Arguments that may need to be interpreted literally, or for which the lazy evaluation mechanism of the language is needed, must not be included in the signature of the generic function, since all arguments in the signature will be evaluated in order to select a method. For example, the argument `expr` to the function `with` is treated literally and must therefore be excluded from the signature.

One would also need to define an implicit generic if the existing non-generic function were not suitable as the default method. Perhaps the function only applies to some classes of objects, and the package designer prefers to have no general default method. In the other direction, the package designer might have some ideas about suitable methods for some classes, if the function were generic. With reasonably modern packages, the simple approach in all these cases is just to define the function as a generic. The implicit generic mechanism is mainly attractive for older packages that do not want to require the methods package to be available.
Generic functions will also be defined but not obviously visible for functions implemented as primitive functions in the base package. Primitive functions look like ordinary functions when printed but are in fact not function objects but objects of two types interpreted by the R evaluator to call underlying C code directly. Since their entire justification is efficiency, R refuses to hide primitives behind a generic function object. Methods may be defined for most primitives, and corresponding metadata objects will be created to store them. Calls to the primitive still go directly to the C code, which will sometimes check for applicable methods. The definition of “sometimes” is that methods must have been detected for the function in some package loaded in the session and isS4(x) is TRUE for the first argument (or for the second argument, in the case of binary operators). You can test whether methods have been detected by calling isGeneric for the relevant function and you can examine the generic function by calling getGeneric, whether or not methods have been detected. For more on generic functions, see the first reference and also section 2 of R Internals.

Method Definitions

All method definitions are stored as objects from the MethodDefinition class. Like the class of generic functions, this class extends ordinary R functions with some additional slots: "generic", containing the name and package of the generic function, and two signature slots, "defined" and "target", the first being the signature supplied when the method was defined by a call to setMethod. The "target" slot starts off equal to the "defined" slot. When an inherited method is cached after being selected, as described above, a copy is made with the appropriate "target" signature. Output from showMethods, for example, includes both signatures.

Method definitions are required to have the same formal arguments as the generic function, since the method dispatch mechanism does not rematch arguments, for reasons of both efficiency and consistency.

Examples

```r
## A class that extends a registered S3 class inherits that class' S3 methods.
setClass("myFrame", contains = "data.frame",
    representation(timestamps = "POSIXt"))

df1 <- data.frame(x = 1:10, y = rnorm(10), z = sample(letters,10))

mydf1 <- new("myFrame", df1, timestamps = Sys.time())

## "myFrame" objects inherit "data.frame" S3 methods; e.g., for `[`
```
mydf[1:2, ] # a data frame object (with extra attributes)

## a method explicitly for "myFrame" class

setMethod("\[", signature(x = "myFrame"),
  function (x, i, j, ..., drop = TRUE)
  {
    S3Part(x) <- callNextMethod()
    x@timestamps <- c(Sys.time(), as.POSIXct(x@timestamps))
    x
  }
)

mydf[1:2, ]

setClass("myDateTime", contains = "POSIXt")

now <- Sys.time() # class(now) is c("POSIXct", "POSIXt")
nowLt <- as.POSIXlt(now) # class(nowLt) is c("POSIXlt", "POSIXt")

mCt <- new("myDateTime", now)
mLt <- new("myDateTime", nowLt)

## S3 methods for an S4 object will be selected using S4 inheritance
## Objects mCt and mLt have different S3Class() values, but this is
## not used.
f3 <- function(x)UseMethod("f3") # an S3 generic to illustrate inheritance

f3.POSIXct <- function(x) "The POSIXct result"
f3.POSIXlt <- function(x) "The POSIXlt result"
f3.POSIXt <- function(x) "The POSIXt result"

stopifnot(identical(f3(mCt), f3.POSIXt(mCt)))
stopifnot(identical(f3(mLt), f3.POSIXt(mLt)))

## An S4 object selects S3 methods according to its S4 "inheritance"

setClass("classA", contains = "numeric",
  representation(realData = "numeric"))

Math.classA <- function(x) {(getFunction("Generic"))(x@realData)}
setMethod("Math", "classA", Math.classA)

x <- new("classA", log(1:10), realData = 1:10)
stopifnot(identical(abs(x), 1:10))

setClass("classB", contains = "classA")
y <- new("classB", x)
stopifnot(identical(abs(y), 1:10)) # (version 2.9.0 or earlier fails here)

## an S3 generic: just for demonstration purposes
f3 <- function(x, ...) UseMethod("f3")

f3.default <- function(x, ...) "Default f3"

## S3 method (only) for classA
f3.classA <- function(x, ...) "Class classA for f3"

## S3 and S4 method for numeric
f3.numeric <- function(x, ...) "Class numeric for f3"
setMethod("f3", "numeric", f3.numeric)

## The S3 method for classA and the closest inherited S3 method for classB
## are not found.

f3(x); f3(y) # both choose "numeric" method

## to obtain the natural inheritance, set identical S3 and S4 methods
setMethod("f3", "classA", f3.classA)

f3(x); f3(y) # now both choose "classA" method

## Need to define an S3 as well as S4 method to use on an S3 object
## or if called from a package without the S4 generic
MathFun <- function(x) { # a smarter "data.frame" method for Math group
  for (i in seq(length = ncol(x))[sapply(x, is.numeric)])
    x[, i] <- (getFunction(.Generic))(x[, i])
  }
  setMethod("Math", "data.frame", MathFun)

## S4 method works for an S4 class containing data.frame,
## but not for data.frame objects (not S4 objects)
try(logIris <- log(iris)) # gets an error from the old method

## Define an S3 method with the same computation
Math.data.frame <- MathFun

logIris <- log(iris)
**Description**

This class of objects was used in the original implementation of the package to control method dispatch. Its use is now deprecated, but objects appear as the default method slot in generic functions. This and any other remaining uses will be removed in the future.

For the modern alternative, see `listOfMethods`.

The details in this documentation are retained to allow analysis of old-style objects.

**Details**

Suppose a function \( f \) has formal arguments \( x \) and \( y \). The methods list object for that function has the object \( \text{as.name("x")} \) as its argument slot. An element of the methods named "track" is selected if the actual argument corresponding to \( x \) is an object of class "track". If there is such an element, it can generally be either a function or another methods list object.

In the first case, the function defines the method to use for any call in which \( x \) is of class "track". In the second case, the new methods list object defines the available methods depending on the remaining formal arguments, in this example, \( y \).

Each method corresponds conceptually to a *signature*; that is a named list of classes, with names corresponding to some or all of the formal arguments. In the previous example, if selecting class "track" for \( x \), finding that the selection was another methods list and then selecting class "numeric" for \( y \) would produce a method associated with the signature \( x \text{ "track" y \text{ "numeric"} } \).

**Slots**

- **argument**: Object of class "name". The name of the argument being used for dispatch at this level.
- **methods**: A named list of the methods (and method lists) defined *explicitly* for this argument. The names are the names of classes, and the corresponding element defines the method or methods to be used if the corresponding argument has that class. See the details below.
- **allMethods**: A named list, contains all the directly defined methods from the **methods** slot, plus any inherited methods. Ignored when methods tables are used for dispatch (see Methods).

**Extends**

Class "OptionalMethods", directly.

---

### MethodWithNext-class

**Class MethodWithNext**

**Description**

Class of method definitions set up for callNextMethod

**Objects from the Class**

Objects from this class are generated as a side-effect of calls to `callNextMethod`. 
Slots

- Data: Object of class "function"; the actual function definition.
- nextMethod: Object of class "PossibleMethod" the method to use in response to a callNextMethod() call.
- excluded: Object of class "list"; one or more signatures excluded in finding the next method.
- target: Object of class "signature". from class "MethodDefinition"
- defined: Object of class "signature", from class "MethodDefinition"
- generic: Object of class "character"; the function for which the method was created.

Extends

Class "MethodDefinition", directly.
Class "function", from data part.
Class "PossibleMethod", by class "MethodDefinition".
Class "OptionalMethods", by class "MethodDefinition".

Methods

- findNextMethod signature(method = "MethodWithNext"): used internally by method dispatch.
- loadMethod signature(method = "MethodWithNext"): used internally by method dispatch.
- show signature(object = "MethodWithNext")

See Also

callNextMethod, and class MethodDefinition.

new Generate an Object from a Class

Description

Given the name or the definition of a class, plus optionally data to be included in the object, new returns an object from that class.

Usage

new(Class, ...)

initialize(.Object, ...)

Arguments

- Class: either the name of a class, a character string, (the usual case) or the object describing the class (e.g., the value returned by getClass).
- ...: data to include in the new object. Named arguments correspond to slots in the class definition. Unnamed arguments must be objects from classes that this class extends.
- .Object: An object: see the Details section.
Details

The function `new` begins by copying the prototype object from the class definition. Then information is inserted according to the ... arguments, if any. As of version 2.4 of R, the type of the prototype object, and therefore of all objects returned by `new()`, is "S4" except for classes that extend one of the basic types, where the prototype has that basic type. User functions that depend on `typeof(object)` should be careful to handle "S4" as a possible type.

Note that the `name` of the first argument, "Class" entails that "Class" is an undesirable slot name in any formal class: `new("myClass", Class = <value>)` will not work.

The interpretation of the `...` arguments can be specialized to particular classes, if an appropriate method has been defined for the generic function "initialize". The new function calls `initialize` with the object generated from the prototype as the `.Object` argument to `initialize`.

By default, unnamed arguments in the `...` are interpreted as objects from a superclass, and named arguments are interpreted as objects to be assigned into the correspondingly named slots. Thus, explicit slots override inherited information for the same slot, regardless of the order in which the arguments appear.

The `initialize` methods do not have to have `...` as their second argument (see the examples). Initialize methods are often written when the natural parameters describing the new object are not the names of the slots. If you do define such a method, note the implications for future subclasses of your class. If these have additional slots, and your `initialize` method has `...` as a formal argument, then your method should pass such arguments along via `callNextMethod`. If your method does not have this argument, then either a subclass must have its own method or else the added slots must be specified by users in some way other than as arguments to `new`.

For examples of `initialize` methods, see `initialize-methods` for existing methods for classes "traceable" and "environment", among others. See the comments there on subclasses of "environment"; any `initialize` methods for these should be sure to allocate a new environment.

Methods for `initialize` can be inherited only by simple inheritance, since it is a requirement that the method return an object from the target class. See the `simpleInheritanceOnly` argument to `setGeneric` and the discussion in `setIs` for the general concept.

Note that the basic vector classes, "numeric", etc. are implicitly defined, so one can use `new` for these classes.

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

See Also

`Classes` for an overview of defining class, and `setOldClass` for the relation to S3 classes.

Examples

```r
## using the definition of class "track" from \link{setClass}

## a new object with two slots specified
t1 <- new("track", x = seq_along(ydata), y = ydata)

# a new object including an object from a superclass, plus a slot
```
t2 <- new("trackCurve", t1, smooth = ysmooth)

### define a method for initialize, to ensure that new objects have
### equal-length x and y slots.

getMethod("initialize",
  "track",
  function(.Object, x = numeric(0), y = numeric(0)) {
    if(nargs() > 1) {
      if(length(x) != length(y))
        stop("specified x and y of different lengths")
      .Object@x <- x
      .Object@y <- y
    }
    .Object
  })

### the next example will cause an error (x will be numeric(0)),
### because we didn’t build in defaults for x,
### although we could with a more elaborate method for initialize

try(new("track", y = sort(stats::rnorm(10))))

## a better way to implement the previous initialize method.
## Why? By using callNextMethod to call the default initialize method
## we don’t inhibit classes that extend “track” from using the general
## form of the new() function. In the previous version, they could only
## use x and y as arguments to new, unless they wrote their own
## initialize method.

getMethod("initialize", "track", function(.Object, ...) {
  .Object <- callNextMethod()
  if(length(.Object@x) != length(.Object@y))
    stop("specified x and y of different lengths")
  .Object
})

---

**nonStructure-class**

*A non-structure S4 Class for basic types*

### Description

S4 classes that are defined to extend one of the basic vector classes should contain the class
`structure` if they behave like structures; that is, if they should retain their class behavior under
math functions or operators, so long as their length is unchanged. On the other hand, if their class
depends on the values in the object, not just its structure, then they should lose that class under any
such transformations. In the latter case, they should be defined to contain `nonStructure`

If neither of these strategies applies, the class likely needs some methods of its own for `Ops`, `Math`,
and/or other generic functions. What is not usually a good idea is to allow such computations to
drop down to the default, base code. This is inconsistent with most definitions of such classes.
ObjectsWithPackage-class

Methods

Methods are defined for operators and math functions (groups Ops, Math and Math2. In all cases the result is an ordinary vector of the appropriate type.

xx <- new("NumericNotStructure", 1:10)
xx + 1 # vector
log(xx) # vector
sample(xx) # vector
promptClass

**Generate a Shell for Documentation of a Formal Class**

**Description**

Assembles all relevant slot and method information for a class, with minimal markup for Rd processing; no QC facilities at present.

**Usage**

```r
promptClass(clName, filename = NULL, type = "class",
            keywords = "classes", where = topenv(parent.frame()),
            generatorName = clName)
```

**Arguments**

- `clName` a character string naming the class to be documented.
- `filename` usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is the topic name for the class documentation, followed by ".Rd". Can also be NA (see below).
- `type` the documentation type to be declared in the output file.
- `keywords` the keywords to include in the shell of the documentation. The keyword "classes" should be one of them.
- `where` where to look for the definition of the class and of methods that use it.
- `generatorName` the name for a generator function for this class; only required if a generator function was created and saved under a name different from the class name.

**Details**

The class definition is found on the search list. Using that definition, information about classes extended and slots is determined.

In addition, the currently available generics with methods for this class are found (using `getGenerics`). Note that these methods need not be in the same environment as the class definition; in particular, this part of the output may depend on which packages are currently in the search list.

As with other prompt-style functions, unless `filename` is NA, the documentation shell is written to a file, and a message about this is given. The file will need editing to give information about the meaning of the class. The output of `promptClass` can only contain information from the metadata about the formal definition and how it is used.

If `filename` is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

If a generator function is found assigned under the class name or the optional `generatorName`, skeleton documentation for that function is added to the file.

**Value**

If `filename` is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.
promptMethods

Generate a Shell for Documentation of Formal Methods

Description

Generates a shell of documentation for the methods of a generic function.

Usage

promptMethods(f, filename = NULL, methods)

Arguments

f

a character string naming the generic function whose methods are to be documented.

filename

usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to the coded topic name for these methods (currently, f followed by "-methods.Rd"). Can also be FALSE or NA (see below).

methods

Optional methods list object giving the methods to be documented. By default, the first methods object for this generic is used (for example, if the current global environment has some methods for f, these would be documented). If this argument is supplied, it is likely to be getMethods(f, where), with where some package containing methods for f.

References

Chambers, John M. (1998) Programming with Data Springer (For the original S4 version.)

See Also

prompt for documentation of functions, promptMethods for documentation of method definitions.

For processing of the edited documentation, either use R CMD Rdconv, or include the edited file in the ‘man’ subdirectory of a package.

Examples

## Not run: > promptClass("track")
A shell of class documentation has been written to the file "track-class.Rd".

## End(Not run)
Details

If `filename` is `FALSE`, the text created is returned, presumably to be inserted some other documentation file, such as the documentation of the generic function itself (see `prompt`).

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

Otherwise, the documentation shell is written to the file specified by `filename`.

Value

If `filename` is `FALSE`, the text generated; if `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

`prompt` and `promptClass`
ReferenceClasses

fields
either a character vector of field names or a named list of the fields. The resulting fields will be accessed with reference semantics (see the section on “Reference Objects”). If the argument is a list, the elements of the list can be the character string name of a class, in which case the field must be from that class or a subclass.

The element in the list can alternatively be an accessor function, a function of one argument that returns the field if called with no argument or sets it to the value of the argument otherwise. Accessor functions are used internally and for inter-system interface applications. Their definition follows the rules for writing methods for the class: they can refer to other fields and can call other methods for this class or its superclasses. See the section on “Implementation” for the internal mechanism used by accessor functions.

Note that fields are distinct from the slots, if any, in the object. Slots are, as always, handled by standard R object management. It is not generally a good idea to mix slots and fields in the same class; this confuses the distinction in behavior between reference classes and regular S4 classes. See the comments in the “Implementation” section.

contains
optional vector of superclasses for this class. If a superclass is also a reference class, the fields and class-based methods will be inherited.

methods
a named list of function definitions that can be invoked on objects from this class. These can also be created by invoking the $methods method on the generator object returned. See the section on “Writing Reference Methods” for details.

Two optional method names are interpreted specially, initialize and finalize. If an initialize method is defined, it will be invoked when an object is generated from the class. See the discussion of method $new(...) in the section “Reference Object Generators”.

If a finalize method is defined, a function will be registered to invoke it before the environment in the object is discarded by the garbage collector. See the matrix viewer example for both initialize and finalize methods.

where
the environment in which to store the class definition (or to begin the search for it, in the case of getClass()). Defaults to the package namespace or environment for code that is part of an R package, and to the global environment for code sourced directly at the session top level.

... other arguments to be passed to getClass.

Value

setRefClass() returns a generator function suitable for creating objects from the class, invisibly. A call to this function takes any number of arguments, which will be passed on to the initialize method. If no initialize method is defined for the class or one of its superclasses, the default method expects named arguments with the name of one of the fields and unnamed arguments, if any, that are objects from one of the superclasses of this class (but only superclasses that are themselves reference classes have any effect).

The generator function is similar to the S4 generator function returned by getClass. In addition to being a generator function, however, it is also a reference class generator object, with reference class methods for various utilities. See the section on reference class generator objects below.

If the class has a method defined for $initialize(), this method will be called once the reference object has been created. You should write such a method for a class that needs to do some special initialization. In particular, a reference method is recommended rather than a method for the S4 generic function initialize(), because some special initialization is required for reference objects
before the initialization of fields. As with S4 classes, methods are written for $initialize()$ and not for $new()$, both for the previous reason and also because $new()$ is invoked on the generator object and would be a method for that class.

The default method for $initialize()$ is equivalent to invoking the method $initFields(...). Named arguments assign initial values to the corresponding fields. Unnamed arguments must be objects from this class or a reference superclass of this class. Fields will be initialized to the contents of the fields in such objects, but named arguments override the corresponding inherited fields. Note that fields are simply assigned. If the field is itself a reference object, that object is not copied. The new and previous object will share the reference. Also, a field assigned from an unnamed argument counts as an assignment for locked fields. To override an inherited value for a locked field, the new value must be one of the named arguments in the initializing call. A later assignment of the field will result in an error.

Initialization methods need some care in design. The generator for a reference class will be called with no arguments, for example when copying the object. To ensure that these calls do not fail, the method must have defaults for all arguments or check for missing(). The method should include ... as an argument and pass this on via $callSuper()$ (or $initFields()$ if you know that your superclasses have no initialization methods). This allows future class definitions that subclass this class, with additional fields.

getRefClass() also returns the generator function for the class. Note that the package slot in the value is the correct package from the class definition, regardless of the where argument, which is used only to find the class if necessary.

Reference Objects

Normal objects in R are passed as arguments in function calls consistently with functional programming semantics; that is, changes made to an object passed as an argument are local to the function call. The object that supplied the argument is unchanged.

The functional model (sometimes called pass-by-value, although this is inaccurate for R) is suitable for many statistical computations and is implicit, for example, in the basic R software for fitting statistical models. In some other situations, one would like all the code dealing with an object to see the exact same content, so that changes made in any computation would be reflected everywhere. This is often suitable if the object has some “objective” reality, such as a window in a user interface.

In addition, commonly used languages, including Java, C++ and many others, support a version of classes and methods assuming reference semantics. The corresponding programming mechanism is to invoke a method on an object. In the R syntax we use "$" for this operation; one invokes a method, m$ say, on an object x by the expression x$m$(...).

Methods in this paradigm are associated with the object, or more precisely with the class of the object, as opposed to methods in a function-based class/method system, which are fundamentally associated with the function (in R, for example, a generic function in an R session has a table of all its currently known methods). In this document “methods for a class” as opposed to “methods for a function” will make the distinction.

Objects in this paradigm are associated with the object, or more precisely with the class of the object, as opposed to methods in a function-based class/method system, which are fundamentally associated with the function (in R, for example, a generic function in an R session has a table of all its currently known methods). In this document “methods for a class” as opposed to “methods for a function” will make the distinction.

Objects in this paradigm usually have named fields on which the methods operate. In the R implementation, the fields are defined when the class is created. The field itself can optionally have a specified class, meaning that only objects from this class or one of its subclasses can be assigned to the field. By default, fields have class "ANY". Fields may also be defined by supplying an accessor function which will be called to get or set the field. Accessor functions are likely when reference classes are part of an inter-system interface. The interface will usually supply the accessor functions automatically based on the definition of the corresponding class in the other language.

Fields are accessed by reference. In particular, invoking a method may modify the content of the fields.
Programming for such classes involves writing new methods for a particular class. In the R implementation, these methods are R functions, with zero or more formal arguments. The object on which the methods are invoked is not an explicit argument to the method. Instead, fields and methods for the class can be referred to by name in the method definition. The implementation uses R environments to make fields and methods available by name. Additional special fields allow reference to the complete object and to the definition of the class. See the section on “Writing Reference Methods”.

The goal of the software described here is to provide a uniform programming style in R for software dealing with reference classes, whether implemented directly in R or through an interface to one of the OOP languages.

Writing Reference Methods

Reference methods are functions supplied as elements of a named list, either when invoking gMethods() on a generator object g or as the argument methods in a call to setRefClass. They are written as ordinary R functions but have some special features and restrictions. The body of the function can contain calls to any other reference method, including those inherited from other reference classes and may refer to fields in the object by name.

Fields may be modified in a method by using the non-local assignment operator, $<-$, as in the $edit and $undo methods in the example below. Note that non-local assignment is required: a local assignment with the $< operator just creates a local object in the function call, as it would in any R function. When methods are installed, a heuristic check is made for local assignments to field names and a warning issued if any are detected.

Reference methods should be kept simple; if they need to do some specialized R computation, that computation should use a separate R function that is called from the reference method. Specifically, methods can not use special features of the enclosing environment mechanism, since the method’s environment is used to access fields and other methods. In particular, methods should not use non-exported entries in the package’s namespace, because the methods may be inherited by a reference class in another package.

Methods for $initialize() have special requirements. See the comments in the “Value” section. Reference methods can not themselves be generic functions; if you want additional function-based method dispatch, write a separate generic function and call that from the method.

The entire object can be referred to in a method by the reserved name .self, as shown in the $save= method of the example. The special object .refClassDef contains the definition of the class of the object. These fields are read-only (it makes no sense to modify these references), with one exception. In principal, the .self field can be modified in the $initialize method, because the object is still being created at this stage. This is definitely not recommended, unless to set some non-reference properties of the object defined for this class, which is itself not recommended if it mixes slots and fields.

The methods available include methods inherited from superclasses, as discussed in the next section. Only methods actually used will be included in the environment corresponding to an individual object. To declare that a method requires a particular other method, the first method should include a call to $usingMethods() with the name of the other method as an argument. Declaring the methods this way is essential if the other method is used indirectly (e.g., via sapply() or do.call()). If it is called directly, code analysis will find it. Declaring the method is harmless in any case, however, and may aid readability of the source code.

Documentation for the methods can be obtained by the $help method for the generator object. Methods for classes are not documented in the Rd format used for R functions. Instead, the $help method prints the calling sequence of the method, followed by self-documentation from the method definition, in the style of Python. If the first element of the body of the method is a literal character
string (possibly multi-line), that string is interpreted as documentation. See the method definitions in the example.

**Inheritance**

Reference classes inherit from other reference classes by using the standard R inheritance; that is, by including the superclasses in the `contains=` argument when creating the new class. The names of the reference superclasses are in slot `refSuperClasses` of the class definition. Reference classes can inherit from ordinary S4 classes also, but this is usually a bad idea if it mixes reference fields and non-reference slots. See the comments in the section on “Implementation”.

Class fields are inherited. A class definition can override a field of the same name in a superclass only if the overriding class is a subclass of the class of the inherited field. This ensures that a valid object in the field remains valid for the superclass as well.

Inherited methods are installed in the same way as directly specified methods. The code in a method can refer to inherited methods in the same way as directly specified methods.

A method may override a method of the same name in a superclass. The overriding method can call the superclass method by `callSuper(....)` as described below.

All reference classes inherit from the class "envRefClass", which provides the following methods.

- `callSuper(....)` Calls the method inherited from a reference superclass. The call is meaningful only from within another method, and will be resolved to call the inherited method of the same name. The arguments to `callSuper` are passed to the superclass version. See the matrix viewer class in the example.
  
  Note that the intended arguments for the superclass method must be supplied explicitly; there is no convention for supplying the arguments automatically, in contrast to the similar mechanism for functional methods.

- `copy(shallow = FALSE)` Creates a copy of the object. With reference classes, unlike ordinary R objects, merely assigning the object with a different name does not create an independent copy. If `shallow` is `FALSE`, any field that is itself a reference object will also be copied, and similarly recursively for its fields. Otherwise, while reassigning a field to a new reference object will have no side effect, modifying such a field will still be reflected in both copies of the object. The argument has no effect on non-reference objects in fields. When there are reference objects in some fields but it is asserted that they will not be modified, using `shallow = TRUE` will save some memory and time.

- `field(name, value)` With one argument, returns the field of the object with character string name. With two arguments, the corresponding field is assigned `value`. Assignment checks that name specifies a valid field, but the single-argument version will attempt to get anything of that name from the object’s environment.
  
  The `field()` method replaces the direct use of a field name, when the name of the field must be calculated, or for looping over several fields.

- `export(Class)` Returns the result of coercing the object to `Class` (typically one of the superclasses of the object’s class). Calling the method has no side effect on the object itself.

- `getRefClass(); getClass()` These return respectively the generator object and the formal class definition for the reference class of this object, efficiently.

- `import(value, Class = class(value))` Import the object `value` into the current object, replacing the corresponding fields in the current object. Object `value` must come from one of the superclasses of the current object’s class. If argument `Class` is supplied, `value` is first coerced to that class.
$initFields(...) Initialize the fields of the object from the supplied arguments. This method is usually only called from a class with a $initialize() method. It corresponds to the default initialization for reference classes. If there are slots and non-reference superclasses, these may be supplied in the ... argument as well.

Typically, a specialized $initialize() method carries out its own computations, then invokes $initFields() to perform standard initialization, as shown in the matrixViewer class in the example below.

$show() This method is called when the object is printed automatically, analogously to the show function. A general method is defined for class "envRefClass". User-defined reference classes will often define their own method: see the Example below.

Note two points in the example. As with any show() method, it is a good idea to print the class explicitly to allow for subclasses using the method. Second, to call the function show() from the method, as opposed to the $show() method itself, refer to methods::show() explicitly.

$trace(what, ...), $untrace(what) Apply the tracing and debugging facilities of the trace function to the reference method what.

All the arguments of the trace function can be supplied, except for signature, which is not meaningful.

The reference method can be invoked on either an object or the generator for the class. See the section on Debugging below for details.

$usingMethods(...) Reference methods used by this method are named as the arguments either quoted or unquoted. In the code analysis phase of installing the the present method, the declared methods will be included. It is essential to declare any methods used in a nonstandard way (e.g., via an apply function). Methods called directly do not need to be declared, but it is harmless to do so. $usingMethods() does nothing at run time.

Objects also inherit two reserved fields:

.self a reference to the entire object;

.refClassDef the class definition.

The defined fields should not override these, and in general it is unwise to define a field whose name begins with ".", since the implementation may use such names for special purposes.

Reference Class Generators

The call to setRefClass defines the specified class and returns a "generator function" object for that class. This object has class "refObjectGenerator"; it inherits from "function" via "classGeneratorFunction" and can be called to generate new objects from the reference class.

The returned object is also a reference class object, although not of the standard construction. It can be used to invoke reference methods and access fields in the usual way, but instead of being implemented directly as an environment it has a subsidiary generator object as a slot, a standard reference object (of class "refGeneratorSlot"). Note that if one wanted to extend the reference class generator capability with a subclass, this should be done by subclassing "refGeneratorSlot", not "refObjectGenerator".

The fields are def, the class definition, and className, the character string name of the class. Methods generate objects from the class, to access help on reference methods, and to define new reference methods for the class. The currently available methods are:

$new(...) This method is equivalent to calling the generator function returned by setRefClass.
$help(topic) Prints brief help on the topic. The topics recognized are reference method names, quoted or not.

The information printed is the calling sequence for the method, plus self-documentation if any. Reference methods can have an initial character string or vector as the first element in the body of the function defining the method. If so, this string is taken as self-documentation for the method (see the section on “Writing Reference Methods” for details).

If no topic is given or if the topic is not a method name, the definition of the class is printed.

$methods(...) With no arguments, returns a list of the reference methods for this class.

Named arguments are method definitions, which will be installed in the class, as if they had been supplied in the methods argument to setRefClass(). Supplying methods in this way, rather than in the call to setRefClass(), is largely for the sake of clearer source code when many or large methods are being defined. All methods for a class should be defined in the source code that defines the class, typically as part of a package. In particular, methods can not be redefined in a class in an attached package with a namespace: The class method checks for a locked binding of the class definition.

The new methods can refer to any currently defined method by name (including other methods supplied in this call to $methods()). Note though that previously defined methods are not re-analyzed meaning that they will not call the new method (unless it redefines an existing method of the same name).

To remove a method, supply NULL as its new definition.

$fields() Returns a list of the fields, each with its corresponding class. Fields for which an accessor function was supplied in the definition have class "activeBindingFunction".

$lock(...) The fields named in the arguments are locked; specifically, after the lock method is called, the field may be set once. Any further attempt to set it will generate an error.

If called with no arguments, the method returns the names of the locked fields.

Fields that are defined by an explicit accessor function can not be locked (on the other hand, the accessor function can be defined to generate an error if called with an argument).

All code to lock fields should normally be part of the definition of a class; that is, the read-only nature of the fields is meant to be part of the class definition, not a dynamic property added later. In particular, fields can not be locked in a class in an attached package with a namespace: The class method checks for a locked binding of the class definition. Locked fields can not be subsequently unlocked.

$trace(what, ..., classMethod = FALSE) Establish a traced version of method what for objects generated from this class. The generator object tracing works like the $trace() method for objects from the class, with two differences. Since it changes the method definition in the class object itself, tracing applies to all objects, not just the one on which the trace method is invoked.

Second, the optional argument classMethod = TRUE allows tracing on the methods of the generator object itself. By default, what is interpreted as the name of a method in the class for which this object is the generator.

$accessors(...) A number of systems using the OOP programming paradigm recommend or enforce getter and setter methods corresponding to each field, rather than direct access by name. If you like this style and want to extract a field named abc by x$getAbc() and assign it by x$setAbc(value), the $accessors method is a convenience function that creates such getter and setter methods for the specified fields. Otherwise there is no reason to use this mechanism. In particular, it has nothing to do with the general ability to define fields by functions as described in the section on “Reference Objects”.

ReferenceClasses
Implementation

Reference classes are implemented as S4 classes with a data part of type "environment". Fields correspond to named objects in the environment. A field associated with a function is implemented as an active binding. In particular, fields with a specified class are implemented as a special form of active binding to enforce valid assignment to the field. A field, say `data`, can be accessed generally by an expression of the form `x$data` for any object from the relevant class. In a method for this class, the field can be accessed by the name `data`. A field that is not locked can be set by an expression of the form `x$data <- value`. Inside a method, a field can be assigned by an expression of the form `x <<- value`. Note the non-local assignment operator. The standard R interpretation of this operator works to assign it in the environment of the object. If the field has an accessor function defined, getting and setting will call that function.

When a method is invoked on an object, the function defining the method is installed in the object’s environment, with the same environment as the environment of the function.

Because of the implementation, new reference classes can inherit from non-reference S4 classes as well as reference classes. This is usually a bad idea, if the slots from the non-reference class are thought of as alternatives to fields. Unless there is some special argument in favor, mixing the functional and reference paradigms for properties of the same object is conceptually unclear. In addition, the initialization method for the class will have to sort out fields from slots, with a good chance of creating anomalous behavior for subclasses of this class. Better in general to define fields analogous to the slots in the S4 class, and to initialize those from an S4 object of that class.

Inter-System Interfaces

A number of languages use a similar reference-based programming model with classes and class-based methods. Aside from differences in choice of terminology and other details, many of these languages are compatible with the programming style described here. R interfaces to the languages exist in a number of packages.

The reference class definitions here provide a hook for classes in the foreign language to be exposed in R. Access to fields and/or methods in the class can be implemented by defining an R reference class corresponding to classes made available through the interface. Typically, the inter-system interface will take care of the details of creating the R class, given a description of the foreign class (what fields and methods it has, the classes for the fields, whether any are read-only, etc.) The specifics for the fields and methods can be implemented via reference methods for the R class. In particular, the use of active bindings allows field access for getting and setting, with actual access handled by the inter-system interface.

R methods and/or fields can be included in the class definition as for any reference class. The methods can use or set fields and can call other methods transparently whether the field or method comes from the interface or is defined directly in R.

For an inter-system interface using this approach, see the code for package Rcpp, version 0.8.7 or later.

Debugging

The standard R debugging and tracing facilities can be applied to reference methods. Reference methods can be passed to `debug` and its relatives from an object to debug further method invocations on that object; for example, `debug(xx$edit)`.

Somewhat more flexible use is available for a reference method version of the `trace` function. A corresponding `$trace()` reference method is available for either an object or for the reference class generator (`xx$trace()` or `mEdit$trace()` in the example below). Using `$trace()` on an object sets up a tracing version for future invocations of the specified method for that object.
$trace()$ on the generator for the class sets up a tracing version for all future objects from that
class (and sometimes for existing objects from the class if the method is not declared or previously
invoked).

In either case, all the arguments to the standard $trace$ function are available, except for $signature$=
which is meaningless since reference methods can not be S4 generic functions. This includes the
typical style $trace(what, browser)$ for interactive debugging and $trace(what, edit = TRUE)$ to
et the reference method interactively.

Examples

```r
## a simple editor for matrix objects. Method $edit()$ changes some
## range of values; method $undo()$ undoes the last edit.

mEdit <- setRefClass("mEdit",
   fields = list( data = "matrix",
                  edits = "list"),
   methods = list(
      edit = function(i, j, value) {
         ## the following string documents the edit method
         'Replaces the range [i, j] of the
         object by value.'
         backup <-
            list(i, j, data[i,j])
         data[i,j] <<- value
         edits <<- c(edits, list(backup))
         invisible(value)
      },
      undo = function() {
         'Undoes the last edit() operation
         and update the edits field accordingly.'
         prev <- edits
         if(length(prev)) prev <<- prev[[length(prev)]]
         else stop("No more edits to undo")
         edit(prev[[1]], prev[[2]], prev[[3]])
         ## trim the edits list
         length(edits) <<- length(edits) - 2
         invisible(prev)
      },
      show = function() {
         'Method for automatically printing matrix editors’
         cat("Reference matrix editor object of class",
             classLabel(class(.self)), "\n")
         cat("Data: \n")
         methods::show(data)
         cat("Undo list is of length", length(edits), "\n")
      }
   )
)

xMat <- matrix(1:12,4,3)
xx <- mEdit(data = xMat)
xx$edit(2, 2, 0)
```
xx
xx$undo()
mEdit$help("undo")
stopifnot(all.equal(xx$data, xMat))

tools::str(xx) # show fields and names of non-trivial methods

## add a method to save the object

Construct a Representation or a Prototype for a Class Definition

Description

These are old utility functions to construct, respectively a list designed to represent the slots and superclasses and a list of prototype specifications. The `representation()` function is no longer useful, since the arguments `slots` and `contains` to `setClass` are now recommended.

The `prototype()` function may still be used for the corresponding argument, but a simple list of the same arguments works as well.

Usage

```r
representation(...) prototype(...)```

Arguments

- ... The call to `representation` takes arguments that are single character strings. Unnamed arguments are classes that a newly defined class extends; named arguments name the explicit slots in the new class, and specify what class each slot should have.

In the call to `prototype`, if an unnamed argument is supplied, it unconditionally forms the basis for the prototype object. Remaining arguments are taken to correspond to slots of this object. It is an error to supply more than one unnamed argument.

Details

The `representation` function applies tests for the validity of the arguments. Each must specify the name of a class.

The classes named don’t have to exist when `representation` is called, but if they do, then the function will check for any duplicate slot names introduced by each of the inherited classes.

The arguments to `prototype` are usually named initial values for slots, plus an optional first argument that gives the object itself. The unnamed argument is typically useful if there is a data part to the definition (see the examples below).

Value

The value of `representation` is just the list of arguments, after these have been checked for validity.

The value of `prototype` is the object to be used as the prototype. Slots will have been set consistently with the arguments, but the construction does not use the class definition to test validity of the contents (it hardly can, since the prototype object is usually supplied to create the definition).

Examples
## representation for a new class with a directly define slot "smooth"
## which should be a "numeric" object, and extending class "track"
representation("track", smooth = "numeric")

setClass("Character", representation("character"))
setClass("TypedCharacter", representation("Character", type = "character"),
prototype(character(0), type = "plain"))
ttt <- new("TypedCharacter", "foo", type = "character")

setClass("num1", representation(comment = "character"),
contains = "numeric",
prototype = prototype(pi, comment = "Start with pi"))

Description
Old-style (S3) classes may be registered as S4 classes (by calling setOldClass, and many have been. These classes can then be contained in (that is, superclasses of) regular S4 classes, allowing formal methods and slots to be added to the S3 behavior. The function $S3Part$ extracts or replaces the S3 part of such an object. $S3Class$ extracts or replaces the S3-style class. $S3Class$ also applies to object from an S4 class with $S3methods=TRUE$ in the call to $setClass$.

See the details below. Also discussed are S3 <-> S4 coercion; see the section “S3 and S4 objects”

Usage
S3Part(object, strictS3 = FALSE, S3Class)
S3Part(object, strictS3 = FALSE, needClass = ) <- value
S3Class(object)
S3Class(object) <- value
isXS3Class(classDef)
slotsFromS3(object)

**Arguments**

- **object**
  - An object from some class that extends a registered S3 class, usually because the class has as one of its superclasses an S3 class registered by a call to `setOldClass`, or from a class that extends a basic vector, matrix or array object type. See the details.
  - For most of the functions, an S3 object can also be supplied, with the interpretation that it is its own S3 part.

- **strictS3**
  - If TRUE, the value returned by `S3Part` will be an S3 object, with all the S4 slots removed. Otherwise, an S4 object will always be returned; for example, from the S4 class created by `setOldClass` as a proxy for an S3 class, rather than the underlying S3 object.

- **S3Class**
  - The character vector to be stored as the S3 class slot in the object. Usually, and by default, retains the slot from `Object`.

- **needClass**
  - Require that the replacement value be this class or a subclass of it.

- **value**
  - For `S3Part<-`, the replacement value for the S3 part of the object. This does not need to be an S4 object; in fact, the usual way to create objects from these classes is by giving an S3 object of the right class as an argument to `new`.
  - For `S3Class<-`, the character vector that will be used as a proxy for `class(x)` in S3 method dispatch. This replacement function can be used to control S3 per-object method selection.

- **classDef**
  - A class definition object, as returned by `getClass`.

**Details**

Classes that register S3 classes by a call to `setOldClass` have slot `.S3Class` to hold the corresponding S3 vector of class strings. The prototype of such a class has the value for this slot determined by the argument to `setOldClass`. Other S4 classes will have the same slot if the argument `S3methods = TRUE` is supplied to `setClass`; in this case, the slot is set to the S4 inheritance of the class.

New S4 classes that extend (contain) such classes also have the same slot, and by default the prototype has the value determined by the `contains=` argument to `setClass`. Individual objects from the S4 class may have an S3 class corresponding to the value in the prototype or to an (S3) subclass of that value. See the examples below.

`S3Part()` with `strictS3 = TRUE` constructs the underlying S3 object by eliminating all the formally defined slots and turning off the S4 bit of the object. With `strictS3 = FALSE` the object returned is from the corresponding S4 class. For consistency and generality, `S3Part()` works also for classes that extend the basic vector, matrix and array classes. Since R is somewhat arbitrary about what it treats as an S3 class ("ts" is, but "matrix" is not), `S3Part()` tries to return an S3 (that is, non-S4) object whenever the S4 class has a suitable superclass, of either S3 or basic object type.

One general application that relies on this generality is to use `S3Part()` to get a superclass object that is guaranteed not to be an S4 object. If you are calling some function that checks for S4 objects, you need to be careful not to end up in a closed loop (fooS4 calls fooS3, which checks for an S4 object and calls fooS4 again, maybe indirectly). Using `S3Part()` with `strictS3 = TRUE` is a mechanism to avoid such loops.
Because the contents of S3 class objects have no definition or guarantee, the computations involving S3 parts do not check for slot validity. Slots are implemented internally in R as attributes, which are copied when present in the S3 part. Grave problems can occur if an S4 class extending an S3 class uses the name of an S3 attribute as the name of an S4 slot, and S3 code sets the attribute to an object from an invalid class according to the S4 definition.

Frequently, S3Part can and should be avoided by simply coercing objects to the desired class; methods are automatically defined to deal correctly with the slots when as is called to extract or replace superclass objects.

The function slotsFromS3() is a generic function used internally to access the slots associated with the S3 part of the object. Methods for this function are created automatically when setOldClass is called with the S4Class argument. Usually, there is only one S3 slot, containing the S3 class, but the S4Class argument may provide additional slots, in the case that the S3 class has some guaranteed attributes that can be used as formal S4 slots. See the corresponding section in the documentation of setOldClass.

Value

S3Part: Returns or sets the S3 information (and possibly some S4 slots as well, depending on arguments S3Class and keepSlots). See the discussion of argument strict above. If it is TRUE the value returned is an S3 object.

S3Class: Returns or sets the character vector of S3 class(es) stored in the object, if the class has the corresponding .S3Class slot. Currently, the function defaults to class otherwise.

isS3Class: Returns TRUE or FALSE according to whether the class defined by ClassDef extends S3 classes (specifically, whether it has the slot for holding the S3 class).

slotsFromS3: returns a list of the relevant slot classes, or an empty list for any other object.

S3 and S4 Objects: Conversion Mechanisms

Objects in R have an internal bit that indicates whether or not to treat the object as coming from an S4 class. This bit is tested by isS4 and can be set on or off by asS4. The latter function, however, does no checking or interpretation; you should only use it if you are very certain every detail has been handled correctly.

As a friendlier alternative, methods have been defined for coercing to the virtual classes "S3" and "S4". The expressions as(object, "S3") and as(object, "S4") return S3 and S4 objects, respectively. In addition, they attempt to do conversions in a valid way, and also check validity when coercing to S4.

The expression as(object, "S3") can be used in two ways. For objects from one of the registered S3 classes, the expression will ensure that the class attribute is the full multi-string S3 class implied by class(object). If the registered class has known attribute.slots, these will also be provided.

Another use of as(object, "S3") is to take an S4 object and turn it into an S3 object with corresponding attributes. This is only meaningful with S4 classes that have a data part. If you want to operate on the object without invoking S4 methods, this conversion is usually the safest way.

The expression as(object, "S4") will use the attributes in the object to create an object from the S4 definition of class(object). This is a general mechanism to create partially defined version of S4 objects via S3 computations (not much different from invoking new with corresponding arguments, but usable in this form even if the S4 object has an initialize method with different arguments).

Examples

```r
## two examples extending S3 class "lm", class "xlm" directly
## and "ylm" indirectly
setClass("xlm", representation(eps = "numeric"), contains = "lm")
setClass("ylm", representation(header = "character"), contains = "xlm")

## lm.D9 is as computed in the example for stats::lm
y1 = new("ylm", lm.D9, header = "test", eps = .1)
xx = new("xlm", lm.D9, eps = .1)
y2 = new("ylm", xx, header = "test")
stopifnot(inherits(y2, "lm"))
stopifnot(identical(y1, y2))
stopifnot(identical(S3Part(y1, strict = TRUE), lm.D9))

## note the these classes can insert an S3 subclass of "lm" as the S3 part:
myData <- data.frame(time = 1:10, y = (1:10)^.5)
myLm <- lm(cbind(y, y^3) ~ time, myData) # S3 class: c("mlm", "lm")
yml = new("ylm", myLm, header = "Example", eps = 0.)

## similar classes to "xlm" and "ylm", but extending S3 class c("mlm", "lm")
setClass("xmm", representation(eps = "numeric"), contains = "mlm")
setClass("ymm", representation(header = "character"), contains = "xmm")

ym2 <- new("ymm", myLm, header = "Example2", eps = .001)

# but for class "ymm", an S3 part of class "lm" is an error:
try(new("ymm", lm.D9, header = "Example2", eps = .001))

setClass("dataFrameD", representation(date = "Date"),
         contains = "data.frame")
myOD <- new("dataFrameD", myData, date = Sys.Date())

## S3Part() applied to classes with a data part (.Data slot)
setClass("NumX", contains="numeric", representation(id="character"))
nn = new("NumX", 1:10, id="test")
stopifnot(identical(1:10, S3Part(nn, strict = TRUE)))

m1 = cbind(group, weight)
setClass("MatX", contains = "matrix", representation(date = "Date"))
mx1 = new("MatX", m1, date = Sys.Date())
stopifnot(identical(mx1, S3Part(mx1, strict = TRUE)))
```
S4groupGeneric  

S4 Group Generic Functions

Description

Methods can be defined for group generic functions. Each group generic function has a number of member generic functions associated with it.

Methods defined for a group generic function cause the same method to be defined for each member of the group, but a method explicitly defined for a member of the group takes precedence over a method defined, with the same signature, for the group generic.

The functions shown in this documentation page all reside in the methods package, but the mechanism is available to any programmer, by calling setGroupGeneric (provided package methods is attached).

Usage

```r
## S4 group generics:
Arith(x1, x2)
Compare(x1, x2)
Ops(x1, x2)
Logic(x1, x2)
Math(x)
Math2(x, digits)
Summary(x, ..., na.rm = FALSE)
Complex(x)
```

Arguments

- `x`, `z`, `e1`, `e2` objects.
- `digits` number of digits to be used in round or signif.
- `...` further arguments passed to or from methods.
- `na.rm` logical: should missing values be removed?

Details

Methods can be defined for the group generic functions by calls to setMethod in the usual way. Note that the group generic functions should never be called directly – a suitable error message will result if they are. When metadata for a group generic is loaded, the methods defined become methods for the members of the group, but only if no method has been specified directly for the member function for the same signature. The effect is that group generic definitions are selected before inherited methods but after directly specified methods. For more on method selection, see Methods.

There are also S3 groups Math, Ops, Summary and Complex, see ?S3groupGeneric, with no corresponding R objects, but these are irrelevant for S4 group generic functions.

The members of the group defined by a particular generic can be obtained by calling getGroupMembers. For the group generic functions currently defined in this package the members are as follows:

- Arith `"+", "-", "+", "/", "/\", "/\", "/\"
Note that Ops merely consists of three sub groups.

All the functions in these groups (other than the group generics themselves) are basic functions in R. They are not by default S4 generic functions, and many of them are defined as primitives. However, you can still define formal methods for them, both individually and via the group generics. It all works more or less as you might expect, admittedly via a bit of trickery in the background. See Methods for details.

Note that two members of the Math group, log and trunc, have ... as an extra formal argument. Since methods for Math will have only one formal argument, you must set a specific method for these functions in order to call them with the extra argument(s).

For further details about group generic functions see section 10.5 of Software for Data Analysis.

Examples

setClass("testComplex", representation(zz = "complex"))
## method for whole group "Complex"
setMethod("Complex", "testComplex",
  function(zz) c("groupMethod", callGeneric(zz@zz)))
## exception for Arg():
setMethod("Arg", "testComplex",
  function(zz) c("ArgMethod", Arg(zz@zz)))
z1 <- 1+2i
z2 <- new("testComplex", zz = z1)
stopifnot(identical(Mod(z2), c("groupMethod", Mod(z1))))
stopifnot(identical(Arg(z2), c("ArgMethod", Arg(z1))))
Scassextension-class  Class to Represent Inheritance (Extension) Relations

Description

An object from this class represents a single ‘is’ relationship; lists of these objects are used to represent all the extensions (superclasses) and subclasses for a given class. The object contains information about how the relation is defined and methods to coerce, test, and replace correspondingly.

Objects from the Class

Objects from this class are generated by setIs, from direct calls and from the contains= information in a call to setClass, and from class unions created by setClassUnion. In the last case, the information is stored in defining the subclasses of the union class (allowing unions to contain sealed classes).

Slots

subClass, superClass: The classes being extended: corresponding to the from, and to arguments to setIs.
package: The package to which that class belongs.
coerce: A function to carry out the as() computation implied by the relation. Note that these functions should not be used directly. They only deal with the strict=TRUE calls to the as function, with the full method constructed from this mechanically.
test: The function that would test whether the relation holds. Except for explicitly specified test arguments to setIs, this function is trivial.
replace: The method used to implement as(x, Class) <- value.
simple: A "logical" flag, TRUE if this is a simple relation, either because one class is contained in the definition of another, or because a class has been explicitly stated to extend a virtual class. For simple extensions, the three methods are generated automatically.
by: If this relation has been constructed transitively, the first intermediate class from the subclass.
dataPart: A "logical" flag, TRUE if the extended class is in fact the data part of the subclass. In this case the extended class is a basic class (i.e., a type).
distance: The distance between the two classes, 1 for directly contained classes, plus the number of generations between otherwise.

Methods

No methods defined with class "SClassExtension" in the signature.

is, as, and the classRepresentation class.
selectSuperClasses

Super Classes (of Specific Kinds) of a Class

Description

Return superclasses of ClassDef, possibly only non-virtual or direct or simple ones.
These functions are designed to be fast, and consequently only work with the contains slot of the corresponding class definitions.

Usage

selectSuperClasses(Class, dropVirtual = FALSE, namesOnly = TRUE,
directOnly = TRUE, simpleOnly = directOnly,
where = topoenv(parent.frame()))

.selectSuperClasses(ext, dropVirtual = FALSE, namesOnly = TRUE,
directOnly = TRUE, simpleOnly = directOnly)

Arguments

- **Class**: name of the class or (more efficiently) the class definition object (see getClass).
- **dropVirtual**: logical indicating if only non-virtual superclasses should be returned.
- **namesOnly**: logical indicating if only a vector names instead of a named list class-extensions should be returned.
- **directOnly**: logical indicating if only a direct super classes should be returned.
- **simpleOnly**: logical indicating if only simple class extensions should be returned.
- **where**: (only used when Class is not a class definition) environment where the class definition of Class is found.
- **ext**: for .selectSuperClasses() only, a list of class extensions, typically getClassDef(..)@contains.

Value

- a character vector (if namesOnly is true, as per default) or a list of class extensions (as the contains slot in the result of getClass).

Note

The typical user level function is selectSuperClasses() which calls .selectSuperClasses(); i.e., the latter should only be used for efficiency reasons by experienced useRs.

See Also

- is, getClass; further, the more technical class classRepresentation documentation.
setClass

Examples

```r
setClass("Root")
setClass("Base", contains = "Root", representation(length = "integer"))
setClass("A", contains = "Base", representation(x = "numeric"))
setClass("B", contains = "Base", representation(y = "character"))
setClass("C", contains = c("A", "B"))
```

```r
extends("C")
selectSuperClasses("C") # "A" "B"
selectSuperClasses("C", direct=FALSE) # "A" "B" "Base" "Root"
selectSuperClasses("C", dropVirt = TRUE, direct=FALSE)# ditto w/o "Root"
```

setClass

Create a Class Definition

Description

Create a class definition, specifying the representation (the slots) and/or the classes contained in this one (the superclasses), plus other optional details. As a side effect, the class definition is stored in the specified environment. A generator function is returned as the value of `setClass()`, suitable for creating objects from the class if the class is not virtual. Of the many arguments to the function only `Class`, `slots` and `contains` are usually needed.

Usage

```r
setClass(Class, representation, prototype, contains=character(),
  validity, access, where, version, sealed, package,
  S3methods = FALSE, slots)
```

Arguments

- **Class** character string name for the class.
- **slots** a named list or named character vector. The names are the names of the slots in the new class and the elements are the character string names of the corresponding classes.
  
  In rare cases where there is ambiguity about the class of a slot, because two classes of the same name are imported from different packages, the corresponding element of the argument must have a "package" attribute to disambiguate the choice.
  
  It is allowed to provide an unnamed character vector as a limiting case, with the elements taken as slot names and all slots having the unrestricted class "ANY".

- **contains** the names (and optionally package slots) for the superclasses of this class. The special superclass "VIRTUAL" causes the new class to be created as a virtual class; see the section on virtual classes in Classes.

- **prototype** an object providing the default data for the slots in this class. By default, each will be the prototype object for the superclass. If provided, using a call to `prototype` will carry out some checks.

- **where** the environment in which to store the definition. Should not be supplied in standard use. For calls to `setClass()` appearing in the source code for a package, will default to the namespace of the package. For calls typed or sourced at the top level in a session, will default to the global environment.
setClass

validity if supplied, should be a validity-checking method for objects from this class (a function that returns TRUE if its argument is a valid object of this class and one or more strings describing the failures otherwise). See validObject for details.

S3methods, representation, access, version
All these arguments are deprecated from version 3.0.0 of R and should be avoided.
S3methods is a flag indicating that old-style methods will be written involving this class. Modern versions of R attempt to match formal and old-style methods consistently, so this argument is largely irrelevant.
representation is an argument inherited from S that included both slots and contains, but the use of the latter two arguments is clearer and recommended.
access and version are included for historical compatibility with S-Plus, but ignored.
sealed if TRUE, the class definition will be sealed, so that another call to setClass will fail on this class name.
package an optional package name for the class. Should very rarely be used. By default the name of the package in which the class definition is assigned.

Value
A generator function suitable for creating objects from the class is returned, invisibly. A call to this function generates a call to new for the class. The call takes any number of arguments, which will be passed on to the initialize method. If no initialize method is defined for the class or one of its superclasses, the default method expects named arguments with the name of one of the slots.
Typically the generator function is assigned the name of the class, for programming clarity. This is not a requirement and objects from the class can also be generated directly from new. The advantages of the generator function are a slightly simpler and clearer call, and that the call will contain the package name of the class (eliminating any ambiguity if two classes from different packages have the same name).
If the class is virtual, an attempt to generate an object from either the generator or new() will result in an error.

Basic Use: Slots and Inheritance
The two essential arguments other than the class name are slots and contains, defining the explicit slots and the inheritance (superclasses). Together, these arguments define all the information in an object from this class; that is, the names of all the slots and the classes required for each of them.
The name of the class determines which methods apply directly to objects from this class. The inheritance information specifies which methods apply indirectly, through inheritance. See Methods.
The slots in a class definition will be the union of all the slots specified directly by slots and all the slots in all the contained classes. There can only be one slot with a given name; specifically, the direct and inherited slot names must be unique. That does not, however, prevent the same class from being inherited via more than one path.
One kind of element in the contains= argument is special, specifying one of the R object types or one of a few other special R types (matrix and array). See the section on inheriting from object types, below.
Slot names "class" and "Class" are not allowed. There are other slot names with a special meaning; these names start with the "." character. To be safe, you should define all of your own slots with names starting with an alphabetic character.
Inheriting from Object Types

In addition to containing other S4 classes, a class definition can contain either an S3 class (see the next section) or a built-in R pseudo-class—one of the R object types or one of the special R pseudo-classes "matrix" and "array". A class can contain at most one of the object types, directly or indirectly. When it does, that contained class determines the "data part" of the class.

Objects from the new class try to inherit the built-in behavior of the contained type. In the case of normal R data types, including vectors, functions and expressions, the implementation is relatively straightforward. For any object x from the class, typeof(x) will be the contained basic type; and a special pseudo-slot, .Data, will be shown with the corresponding class. See the "numWithId" example below.

Classes may also inherit from "vector", "matrix" or "array". The data part of these objects can be any vector data type.

For an object from any class that does not contain one of these types or classes, typeof(x) will be "S4".

Some R data types do not behave normally, in the sense that they are non-local references or other objects that are not duplicated. Examples include those corresponding to classes "environment", "externalptr", and "name". These can not be the types for objects with user-defined classes (either S4 or S3) because setting an attribute overwrites the object in all contexts. It is possible to define a class that inherits from such types, through an indirect mechanism that stores the inherited object in a reserved slot. See the example for class "stampedEnv" below. S3 method dispatch and the relevant as.type() functions should behave correctly, but code that uses the type of the object directly will not.

Also, keep in mind that the object passed to low-level computations will be the underlying object type, without any of the slots defined in the class. To return the full information, you will usually have to define a method that sets the data part.

Inheriting from S3 Classes

Old-style S3 classes have no formal definition. Objects are "from" the class when their class attribute contains the character string considered to be the class name.

Using such classes with formal classes and methods is necessarily a risky business, since there are no guarantees about the content of the objects or about consistency of inherited methods. Given that, it is still possible to define a class that inherits from an S3 class, providing that class has been registered as an old class (see setOldClass).

Broadly speaking, both S3 and S4 method dispatch try to behave sensibly with respect to inheritance in either system. Given an S4 object, S3 method dispatch and the inherits function should use the S4 inheritance information. Given an S3 object, an S4 generic function will dispatch S4 methods using the S3 inheritance, provided that inheritance has been declared via setOldClass.

Classes and Packages

Class definitions normally belong to packages (but can be defined in the global environment as well, by evaluating the expression on the command line or in a file sourced from the command line). The corresponding package name is part of the class definition; that is, part of the classRepresentation object holding that definition. Thus, two classes with the same name can exist in different packages, for most purposes.

When a class name is supplied for a slot or a superclass in a call to setClass, a corresponding class definition will be found, looking from the namespace of the current package, assuming the call in question appears directly in the source for the package, as it should to avoid ambiguity. The class definition must be found in the namespace of the current package, in the imports for that namespace.
or in the basic classes defined by the methods package. (The methods package must be included in the Depends directive of the package’s “DESCRIPTION” file in order for the “CMD check” utility to find these classes.)

When this rule does not identify a class uniquely (because it appears in more than one imported package) then the packageSlot of the character string name needs to be supplied with the name. This should be a rare occurrence.

Examples

```r
## A simple class with two slots
track <- setClass("track",
                slots = c(x="numeric", y="numeric"))
## an object from the class
t1 <- track(x = 1:10, y = 1:10 + rnorm(10))

## A class extending the previous, adding one more slot
trackCurve <- setClass("trackCurve",
                slots = c(smooth = "numeric"),
                contains = "track")

## an object containing a superclass object
t1s <- trackCurve(t1, smooth = 1:10)

## A class similar to "trackCurve", but with different structure
## allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve",
        slots = c(x="numeric", y="matrix", smooth="matrix"),
        prototype = list(x=numeric(), y=matrix(0,0,0),
                         smooth= matrix(0,0,0)))
## See ?setIs for further examples using these classes

## A class that extends the built-in data type "numeric"
numWithId <- setClass("numWithId", slots = c(id = "character"),
                     contains = "numeric")
numWithId(1:3, id = "An Example")

## inherit from reference object of type "environment"
stampedEnv <- setClass("stampedEnv", contains = "environment",
                      slots = c(update = "POSIXct"))
setMethod("[[<-", c("stampedEnv", "character", "missing"),
           function(x, i, j, ..., value) {
              ev <- as(x, "environment")
              ev[i, j, ...] <- value
           })
```
Classes Defined as the Union of Other Classes

Description
A class may be defined as the union of other classes; that is, as a virtual class defined as a superclass of several other classes. Class unions are useful in method signatures or as slots in other classes, when we want to allow one of several classes to be supplied.

Usage
setClassUnion(name, members, where)
isClassUnion(Class)

Arguments
name the name for the new union class.
members the classes that should be members of this union.
where where to save the new class definition; by default, the environment of the package in which the setClassUnion call appears, or the global environment if called outside of the source of a package.

Details
The classes in members must be defined before creating the union. However, members can be added later on to an existing union, as shown in the example below. Class unions can be members of other class unions.

The prototype object in the class union definition will be NULL if class "NULL" is a member of the union and the prototype object of the first member class otherwise (as of version 2.15.0 of R; earlier versions had a NULL prototype even if that was not valid).

Class unions are the only way to create a class that is extended by a class whose definition is sealed (for example, the basic datatypes or other classes defined in the base or methods package in R are sealed). You cannot say setIs("function", "other") unless "other" is a class union. In general, a setIs call of this form changes the definition of the first class mentioned (adding "other" to the list of superclasses contained in the definition of "function").

Class unions get around this by not modifying the first class definition, relying instead on storing information in the subclasses slot of the class union. In order for this technique to work, the internal computations for expressions such as extends(class1, class2) work differently for class

```r
ev[i] <- value # update the object in the environment
x$update <- Sys.time() # and the update time
x

e1 <- stampedEnv(update = Sys.time())
e1["noise"] <- rnorm(10)
```

**setClassUnion**
unions than for regular classes; specifically, they test whether any class is in common between the superclasses of class1 and the subclasses of class2.

The different behavior for class unions is made possible because the class definition object for class unions has itself a special class, "ClassUnionRepresentation", an extension of class classRepresentation.

References

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

Examples

```r
## a class for either numeric or logical data
setClassUnion("maybeNumber", c("numeric", "logical"))

## use the union as the data part of another class
setClass("withId", representation("maybeNumber", id = "character"))

wl <- new("withId", 1:10, id = "test 1")
w2 <- new("withId", sqrt(wl)^3/1 < .01, id = "Perfect squares")

## add class "complex" to the union "maybeNumber"
setIs("complex", "maybeNumber")

w3 <- new("withId", complex(real = 1:10, imaginary = sqrt(1:10)))

## a class union containing the existing class union "OptionalFunction"
setClassUnion("maybeCode",
    c("expression", "language", "OptionalFunction"))

is(quote(sqrt(1:10)), "maybeCode")  ## TRUE
```

---

**setGeneric**

**Define a New Generic Function**

**Description**

Create a new generic function of the given name, that is, a function that dispatches methods according to the classes of the arguments, from among the formal methods defined for this function.

**Usage**

```r
setGeneric(name, def=, group=list(), valueClass=character(),
    where=, package=, signature=, useAsDefault=,
    genericFunction=, simpleInheritanceOnly = )

setGroupGeneric(name, def=, group=list(), valueClass=character(),
    knownMembers=list(), package=, where= )
```
Arguments

name
The character string name of the generic function. The simplest (and recommended) call, `setGeneric(name)`, looks for a function with this name and creates a corresponding generic function, if the function found was not generic. In the latter case, the existing function becomes the default method.

def
An optional function object, defining the generic. Don’t supply this argument if you want to turn an existing non-generic function into a generic. In this case, you usually want to use the simple call with one argument.

Do supply def if there is no current function of this name or for some reason you do not want to use that function to define the generic. In that case, the formal arguments and default values for the generic are taken from def. In most cases, the body of def will then define the default method, as the existing function did in the one-argument call.

If you want to create a new generic function with no default method, then def should be only a call to `standardGeneric` with the same character string as name.

group
Optionally, a character string giving the name of the group generic function to which this function belongs. See Methods for details of group generic functions in method selection.

valueClass
An optional character vector of one or more class names. The value returned by the generic function must have (or extend) this class, or one of the classes; otherwise, an error is generated.

package
The name of the package with which this function is associated. Usually determined automatically (as the package containing the non-generic version if there is one, or else the package where this generic is to be saved).

where
Where to store the resulting initial methods definition, and possibly the generic function; by default, stored into the top-level environment.

signature
Optionally, the vector of names, from among the formal arguments to the function, that can appear in the signature of methods for this function, in calls to `setMethod`. If ... is one of the formal arguments, it is treated specially. Starting with version 2.8.0 of R, ... may be signature of the generic function. Methods will then be selected if their signature matches all the ... arguments. See the documentation for topic dotsMethods for details. In the present version, it is not possible to mix ... and other arguments in the signature (this restriction may be lifted in later versions).

By default, the signature is inferred from the implicit generic function corresponding to a non-generic function. If no implicit generic function has been defined, the default is all the formal arguments except ..., in the order they appear in the function definition. In the case that ... is the only formal argument, that is also the default signature. To use ... as the signature in a function that has any other arguments, you must supply the signature argument explicitly. See the “Implicit Generic” section below for more details.

useAsDefault
Override the usual choice of default argument. Argument useAsDefault can be supplied, either as a function to use for the default, or as a logical value. This argument is now rarely needed. See the section on details.

simpleInheritanceOnly
Supply this argument as TRUE to require that methods selected be inherited through simple inheritance only; that is, from superclasses specified in the contains= argument to `setClass`, or by simple inheritance to a class union
setGeneric or other virtual class. Generic functions should require simple inheritance if they need to be assured that they get the complete original object, not one that has been transformed. Examples of functions requiring simple inheritance are initialize, because by definition it must return an object from the same class as its argument, and show, because it claims to give a full description of the object provided as its argument.

genericFunction
Don’t use; for (possible) internal use only.

knownMembers (For setGroupGeneric only.) The names of functions that are known to be members of this group. This information is used to reset cached definitions of the member generics when information about the group generic is changed.

Value
The setGeneric function exists for its side effect: saving the generic function to allow methods to be specified later. It returns name.

Basic Use
The setGeneric function is called to initialize a generic function as preparation for defining some methods for that function.

The simplest and most common situation is that name is already an ordinary non-generic non-primitive function, and you now want to turn this function into a generic. In this case you will most often supply only name, for example:

setGeneric("colSums")

There must be an existing function of this name, on some attached package (in this case package "base"). A generic version of this function will be created in the current package (or in the global environment if the call to setGeneric is from an ordinary source file or is entered on the command line). The existing function becomes the default method, and the package slot of the new generic function is set to the location of the original function ("base" in the example). It’s an important feature that the same generic function definition is created each time, depending in the example only on the definition of print and where it is found. The signature of the generic function, defining which of the formal arguments can be used in specifying methods, is set by default to all the formal arguments except . . . .

Note that calling setGeneric in this form is not strictly necessary before calling setMethod for the same function. If the function specified in the call to setMethod is not generic, setMethod will execute the call to setGeneric itself. Declaring explicitly that you want the function to be generic can be considered better programming style; the only difference in the result, however, is that not doing so produces a message noting the creation of the generic function.

You cannot (and never need to) create an explicit generic version of the primitive functions in the base package. Those which can be treated as generic functions have methods selected and dispatched from the internal C code, to satisfy concerns for efficiency, and the others cannot be made generic. See the section on Primitive Functions below.

The description above is the effect when the package that owns the non-generic function has not created an implicit generic version. Otherwise, it is this implicit generic function that is used. See the section on Implicit Generic Functions below. Either way, the essential result is that the same version of the generic function will be created each time.

The second common use of setGeneric is to create a new generic function, unrelated to any existing function, and frequently having no default method. In this case, you need to supply a skeleton of the function definition, to define the arguments for the function. The body of a generic
function is usually a standard form, \texttt{standardGeneric(name)} where \texttt{name} is the quoted name of the generic function. When calling \texttt{setGeneric} in this form, you would normally supply the \texttt{def} argument as a function of this form. See the second and third examples below.

The \texttt{useAsDefault} argument controls the default method for the new generic. If not told otherwise, \texttt{setGeneric} will try to find a non-generic version of the function to use as a default. So, if you do have a suitable default method, it is often simpler to first set this up as a non-generic function, and then use the one-argument call to \texttt{setGeneric} at the beginning of this section. See the first example in the Examples section below.

If you don’t want the existing function to be taken as default, supply the argument \texttt{useAsDefault}. That argument can be the function you want to be the default method, or \texttt{FALSE} to force no default (i.e., to cause an error if there is no direct or inherited method selected for a call to the function).

### Details

The great majority of calls to \texttt{setGeneric()} should either have one argument to ensure that an existing function can have methods, or arguments \texttt{name} and \texttt{def} to create a new generic function and optionally a default method. If that’s not what you plan to do, read on.

If you want to change the behavior of an existing function (typically, one in another package) when you create a generic version, you must supply arguments to \texttt{setGeneric} correspondingly. Whatever changes are made, the new generic function will be assigned with a package slot set to the current package, not the one in which the non-generic version of the function is found. This step is required because the version you are creating is no longer the same as that implied by the function in the other package. A message will be printed to indicate that this has taken place and noting one of the differences between the two functions. It tends to be a bad idea, because the two versions are now competing for methods, with many chances for mistakes in programming.

The body of a generic function usually does nothing except for dispatching methods by a call to \texttt{standardGeneric}. Under some circumstances you might just want to do some additional computation in the generic function itself. As long as your function eventually calls \texttt{standardGeneric} that is permissible (though perhaps not a good idea, in that it may make the behavior of your function less easy to understand). If your explicit definition of the generic function does \texttt{not} call \texttt{standardGeneric} you are in trouble, because none of the methods for the function will ever be dispatched.

By default, the generic function can return any object. If \texttt{valueClass} is supplied, it should be a vector of class names; the value returned by a method is then required to satisfy \texttt{is(object, class)} for one of the specified classes. An empty (i.e., zero length) vector of classes means anything is allowed. Note that more complicated requirements on the result can be specified explicitly, by defining a non-standard generic function.

The \texttt{setGroupGeneric} function behaves like \texttt{setGeneric} except that it constructs a group generic function, differing in two ways from an ordinary generic function. First, this function cannot be called directly, and the body of the function created will contain a stop call with this information. Second, the group generic function contains information about the known members of the group, used to keep the members up to date when the group definition changes, through changes in the search list or direct specification of methods, etc.

### Implicit Generic Functions

Saying that a non-generic function “is converted to a generic” is more precisely state that the function is converted to the corresponding \texttt{implicit} generic function. If no special action has been taken, any function corresponds implicitly to a generic function with the same arguments, in which all arguments other than \ldots can be used. The signature of this generic function is the vector of formal arguments, in order, except for \ldots
The source code for a package can define an implicit generic function version of any function in that package (see `implicitGeneric` for the mechanism). You can not, generally, define an implicit generic function in someone else’s package. The usual reason for defining an implicit generic is to prevent certain arguments from appearing in the signature, which you must do if you want the arguments to be used literally or if you want to enforce lazy evaluation for any reason. An implicit generic can also contain some methods that you want to be predefined; in fact, the implicit generic can be any generic version of the non-generic function. The implicit generic mechanism can also be used to prohibit a generic version (see `prohibitGeneric`).

Whether defined or inferred automatically, the implicit generic will be compared with the generic function that `setGeneric` creates, when the implicit generic is in another package. If the two functions are identical, then the package slot of the created generic will have the name of the package containing the implicit generic. Otherwise, the slot will be the name of the package in which the generic is assigned.

The purpose of this rule is to ensure that all methods defined for a particular combination of generic function and package names correspond to a single, consistent version of the generic function. Calling `setGeneric` with only name and possibly package as arguments guarantees getting the implicit generic version, if one exists.

Including any of the other arguments can force a new, local version of the generic function. If you don’t want to create a new version, don’t use the extra arguments.

### Generic Functions and Primitive Functions

A number of the basic R functions are specially implemented as primitive functions, to be evaluated directly in the underlying C code rather than by evaluating an R language definition. Most have implicit generics (see `implicitGeneric`), and become generic as soon as methods (including group methods) are defined on them. Others cannot be made generic.

Even when methods are defined for such functions, the generic version is not visible on the search list, in order that the C version continues to be called. Method selection will be initiated in the C code. Note, however, that the result is to restrict methods for primitive functions to signatures in which at least one of the classes in the signature is a formal S4 class.

To see the generic version of a primitive function, use `getGeneric(name)`. The function `isGeneric` will tell you whether methods are defined for the function in the current session.

Note that S4 methods can only be set on those primitives which are ‘internal generic’, plus %*%.

### See Also

Methods and the links there for a general discussion, `dottedMethods` for methods that dispatch on “…” and `setMethod` for method definitions.

### Examples

```r
## create a new generic function, with a default method
setGeneric("props", function(object) attributes(object))

## A new generic function with no default method
```
setGeneric("increment", 
  function(object, step, ...) 
  standardGeneric("increment") 
) 

### A non-standard generic function. It insists that the methods 
### return a non-empty character vector (a stronger requirement than 
### valueClass = "character" in the call to setGeneric)

setGeneric("authorNames", 
  function(text) { 
    value <- standardGeneric("authorNames") 
    if(!is(value, "character") && any(nchar(value)>0)) 
      stop("authorNames methods must return non-empty strings") 
    value 
  })

## An example of group generic methods, using the class 
## "track"; see the documentation of \link(setClass) for its definition

## define a method for the Arith group

setMethod("Arith", c("track", "numeric"), 
  function(e1, e2) { 
    e1@y <- callGeneric(e1@y, e2) 
    e1 
  })

setMethod("Arith", c("numeric", "track"), 
  function(e1, e2) { 
    e2@y <- callGeneric(e1, e2@y) 
    e2 
  })

## now arithmetic operators will dispatch methods:

t1 <- new("track", x=1:10, y=sort(stats::rnorm(10)))

t1 - 100 
1/t1

---

**Description**

These functions provide a mechanism for packages to specify computations to be done during the loading of a package namespace. Such actions are a flexible way to provide information only available at load time (such as locations in a dynamically linked library).
A call to `setLoadAction()` or `setLoadActions()` specifies one or more functions to be called when the corresponding namespace is loaded, with the ... argument names being used as identifying names for the actions.

`getLoadActions()` reports the currently defined load actions, given a package's namespace as its argument.

`hasLoadAction()` returns TRUE if a load action corresponding to the given name has previously been set for the where namespace.

`evalOnLoad()` and `evalqOnLoad()` schedule a specific expression for evaluation at load time.

**Usage**

```plaintext
setLoadAction(action, aname=, where=)
setLoadActions(..., .where=)
getLoadActions(where=)
hasLoadAction(aname, where=)
evalOnLoad(expr, where=, aname=)
evalqOnLoad(expr, where=, aname=)
```

**Arguments**

- **action, ...** functions of one or more arguments, to be called when this package is loaded. The functions will be called with one argument (the package namespace) so all following arguments must have default values.
  
  If the elements of ... are named, these names will be used for the corresponding load metadata.

- **where, .where** the namespace of the package for which the list of load actions are defined. This argument is normally omitted if the call comes from the source code for the package itself, but will be needed if a package supplies load actions for another package.

- **aname** the name for the action. If an action is set without supplying a name, the default uses the position in the sequence of actions specified (".1", etc.).

- **expr** an expression to be evaluated in a load action in environment where. In the case of `evalqOnLoad()`, the expression is interpreted literally, in that of `evalOnLoad()` it must be precomputed, typically as an object of type "language".

**Details**

The `evalOnLoad()` and `evalqOnLoad()` functions are for convenience. They construct a function to evaluate the expression and call `setLoadAction()` to schedule a call to that function.

Each of the functions supplied as an argument to `setLoadAction()` or `setLoadActions()` is saved as metadata in the namespace, typically that of the package containing the call to `setLoadActions()`. When this package's namespace is loaded, each of these functions will be called. Action functions are called in the order they are supplied to `setLoadActions()`. The objects assigned have metadata names constructed from the names supplied in the call; unnamed arguments are taken to be named by their position in the list of actions (".1", etc.).
setLoadActions

Multiple calls to `setLoadAction()` or `setLoadActions()` can be used in a package’s code; the actions will be scheduled after any previously specified, except if the name given to `setLoadAction()` is that of an existing action. In typical applications, `setLoadActions()` is more convenient when calling from the package’s own code to set several actions. Calls to `setLoadAction()` are more convenient if the action name is to be constructed, which is more typical when one package constructs load actions for another package.

Actions can be revised by assigning with the same name, actual or constructed, in a subsequent call. The replacement must still be a valid function, but can of course do nothing if the intention was to remove a previously specified action.

The functions must have at least one argument. They will be called with one argument, the namespace of the package. The functions will be called at the end of processing of S4 metadata, after dynamically linking any compiled code, the call to `.onLoad()`, if any, and caching method and class definitions, but before the namespace is sealed. (Load actions are only called if methods dispatch is on.)

Functions may therefore assign or modify objects in the namespace supplied as the argument in the call. The mechanism allows packages to save information not available until load time, such as values obtained from a dynamically linked library.

Load actions should be contrasted with user load hooks supplied by `setHook()`. User hooks are generally provided from outside the package and are run after the namespace has been sealed. Load actions are normally part of the package code, and the list of actions is normally established when the package is installed.

Load actions can be supplied directly in the source code for a package. It is also possible and useful to provide facilities in one package to create load actions in another package. The software needs to be careful to assign the action functions in the correct environment, namely the namespace of the target package.

Value

`setLoadAction()` and `setLoadActions()` are called for their side effect and return no useful value.

`getLoadActions()` returns a named list of the actions in the supplied namespace.

`hasLoadAction()` returns TRUE if the specified action name appears in the actions for this package.

See Also

`setHook` for safer (since they are run after the namespace is sealed) and more comprehensive versions in the base package.

Examples

```r
## Not run:
## in the code for some package

## ... somewhere else
setLoadActions(function(ns)
  cat("Loaded package", , sQuote(getNamespaceName(ns)),
    "at", format(Sys.time()), "\n"),
  function(ns) assign("myCount", 1, envir = ns),
  function(ns) assign("myPointer", getMyExternalPointer(), envir = ns))
... somewhere later
if(countShouldBe0)
  setLoadAction(function(ns) assign("myCount", 0, envir = ns), "setCount")
```
setMethod

Create and Save a Method

Description

Create and save a formal method for a given function and list of classes.

Usage

```r
setMethod(f, signature=character(), definition,
where = .topenv(parent.frame()),
valueClass = NULL, sealed = FALSE)
```

```r
removeMethod(f, signature, where)
```

Arguments

- **f**: A generic function or the character-string name of the function.
- **signature**: A match of formal argument names for `f` with the character-string names of corresponding classes. See the details below; however, if the signature is not trivial, you should use `method.skeleton` to generate a valid call to `setMethod`.
- **definition**: A function definition, which will become the method called when the arguments in a call to `f` match the classes in `signature`, directly or through inheritance.
- **where**: the environment in which to store the definition of the method. For `setMethod`, it is recommended to omit this argument and to include the call in source code that is evaluated at the top level; that is, either in an R session by something equivalent to a call to `source`, or as part of the R source code for a package. For `removeMethod`, the default is the location of the (first) instance of the method for this signature.
- **valueClass**: Obsolete and unused, but see the same argument for `setGeneric`.
- **sealed**: If TRUE, the method so defined cannot be redefined by another call to `setMethod` (although it can be removed and then re-assigned).

Details

The call to `setMethod` stores the supplied method definition in the metadata table for this generic function in the environment, typically the global environment or the namespace of a package. In the case of a package, the table object becomes part of the namespace or environment of the package. When the package is loaded into a later session, the methods will be merged into the table of methods in the corresponding generic function object.

Generic functions are referenced by the combination of the function name and the package name; for example, the function "show" from the package "methods". Metadata for methods is identified by the two strings; in particular, the generic function object itself has slots containing its name and its package name. The package name of a generic is set according to the package from which it originally comes; in particular, and frequently, the package where a non-generic version of the function originated. For example, generic functions for all the functions in package `base` will have "base" as the package name, although none of them is an S4 generic on that package. These include
setMethod

Most of the base functions that are primitives, rather than true functions; see the section on primitive functions in the documentation for `setGeneric` for details.

Multiple packages can have methods for the same generic function; that is, for the same combination of generic function name and package name. Even though the methods are stored in separate tables in separate environments, loading the corresponding packages adds the methods to the table in the generic function itself, for the duration of the session.

The class names in the signature can be any formal class, including basic classes such as "numeric", "character", and "matrix". Two additional special class names can appear: "ANY", meaning that this argument can have any class at all; and "missing", meaning that this argument must not appear in the call in order to match this signature. Don’t confuse these two: if an argument isn’t mentioned in a signature, it corresponds implicitly to class "ANY", not to "missing". See the example below. Old-style (‘S3’) classes can also be used, if you need compatibility with these, but you should definitely declare these classes by calling `setOldClass` if you want S3-style inheritance to work.

Method definitions can have default expressions for arguments, but a current limitation is that the generic function must have some default expression for the same argument in order for the method’s defaults to be used. If so, and if the corresponding argument is missing in the call to the generic function, the default expression in the method is used. If the method definition has no default for the argument, then the expression supplied in the definition of the generic function itself is used, but note that this expression will be evaluated using the enclosing environment of the method, not of the generic function. Note also that specifying class "missing" in the signature does not require any default expressions, and method selection does not evaluate default expressions. All actual (non-missing) arguments in the signature of the generic function will be evaluated when a method is selected—when the call to `standardGeneric(f)` occurs.

It is possible to have some differences between the formal arguments to a method supplied to `setMethod` and those of the generic. Roughly, if the generic has ... as one of its arguments, then the method may have extra formal arguments, which will be matched from the arguments matching ... in the call to f. (What actually happens is that a local function is created inside the method, with the modified formal arguments, and the method is re-defined to call that local function.)

Method dispatch tries to match the class of the actual arguments in a call to the available methods collected for f. If there is a method defined for the exact same classes as in this call, that method is used. Otherwise, all possible signatures are considered corresponding to the actual classes or to superclasses of the actual classes (including "ANY"). The method having the least distance from the actual classes is chosen; if more than one method has minimal distance, one is chosen (the lexicographically first in terms of superclasses) but a warning is issued. All inherited methods chosen are stored in another table, so that the inheritance calculations only need to be done once per session per sequence of actual classes. See `Methods` for more details.

The function `removeMethod` removes the specified method from the metadata table in the corresponding environment. It’s not a function that is used much, since one normally wants to redefine a method rather than leave no definition.

Value

These functions exist for their side-effect, in setting or removing a method in the object defining methods for the specified generic.

The value returned by `removeMethod` is TRUE if a method was found to be removed.

Examples

```r
require(graphics)
## methods for plotting track objects (see the example for \link(setClass))
##
## First, with only one object as argument:
setMethod("plot", signature(x="track", y="missing"),
  function(x, y, ...) plot(slot(x, "x"), slot(x, "y"), ...)
)
## Second, plot the data from the track on the y-axis against anything
## as the x data.
setMethod("plot", signature(y = "track"),
  function(x, y, ...) plot(x, slot(y, "y"), ...)
)
## and similarly with the track on the x-axis (using the short form of
## specification for signatures)
setMethod("plot", "track",
  function(x, y, ...) plot(slot(x, "y"), y, ...)
)
t1 <- new("track", x=1:20, y=(1:20)^2)
tcl <- new("trackCurve", t1)
slot(tcl, "smooth") <- smooth.spline(slot(tcl, "x"), slot(tcl, "y"))
plot(t1)
plot(qnorm(ppoints(20)), t1)
## An example of inherited methods, and of conforming method arguments
## (note the dotCurve argument in the method, which will be pulled out
## of ... in the generic.
setMethod("plot", c("trackCurve", "missing"),
  function(x, y, dotCurve = FALSE, ...) {
    plot(as(x, "track"))
    if(length(slot(x, "smooth") > 0))
      lines(slot(x, "x"), slot(x, "smooth"),
      lty = if(is(dotCurve) 2 else 1)
  }
)
## the plot of tcl alone has an added curve; other uses of tcl
## are treated as if it were a "track" object.
plot(tcl, dotCurve = TRUE)
plot(qnorm(ppoints(20)), tcl)
## defining methods for a special function.
## Although "," and "length" are not ordinary functions
## methods can be defined for them.
setMethod(",", "track",
  function(x, i, j, ..., drop) {
    x@x <- x@x[i]; x@y <- x@y[i]
    x
  })
plot(t1[1:15])
```
setMethod("length", "track", function(x)length(x@y))
length(t1)

## methods can be defined for missing arguments as well
setGeneric("summary") ## make the function into a generic

## A method for summary()
## The method definition can include the arguments, but
## if they're omitted, class "missing" is assumed.
setMethod("summary", "missing", function() "<No Object>")

---

**setOldClass**

Register Old-Style (S3) Classes and Inheritance

### Description

Register an old-style (a.k.a. ‘S3’) class as a formally defined class. The Classes argument is the character vector used as the class attribute; in particular, if there is more than one string, old-style class inheritance is mimicked. Registering via setOldClass allows S3 classes to appear in method signatures, as a slot in an S4 class, or as a superclass of an S4 class.

### Usage

setOldClass(Classes, prototype, where, test = FALSE, S4Class)

### Arguments

**Classes**  
A character vector, giving the names for S3 classes, as they would appear on the right side of an assignment of the class attribute in S3 computations. In addition to S3 classes, an object type or other valid data part can be specified, if the S3 class is known to require its data to be of that form.

**prototype**  
An optional object to use as the prototype. This should be provided as the default S3 object for the class. If omitted, the S4 class created to register the S3 class is VIRTUAL. See the details.

**where**  
Where to store the class definitions, the global or top-level environment by default. (When either function is called in the source for a package, the class definitions will be included in the package’s environment by default.)

**test**  
flag, if TRUE, arrange to test inheritance explicitly for each object, needed if the S3 class can have a different set of class strings, with the same first string. This is a different mechanism in implementation and should be specified separately for each pair of classes that have an optional inheritance. See the ‘Details’.

**S4Class**  
optionally, the class definition or the class name of an S4 class. The new class will have all the slots and other properties of this class, plus its S3 inheritance as defined by the Classeses argument. Arguments prototype and test must not be supplied in this case. See the section on “S3 classes with known attributes” below.
setOldClass

Details

Each of the names will be defined as an S4 class, extending the remaining classes in Classes, and the class oldClass, which is the 'root' of all old-style classes. S3 classes have no formal definition, and therefore no formally defined slots. If a prototype argument is supplied in the call to setOldClass(), objects from the class can be generated, by a call to new; however, this usually not as relevant as generating objects from subclasses (see the section on extending S3 classes below). If a prototype is not provided, the class will be created as a virtual S4 class. The main disadvantage is that the prototype object in an S4 class that uses this class as a slot will have a NULL object in that slot, which can sometimes lead to confusion.

Beginning with version 2.8.0 of R, support is provided for using a (registered) S3 class as a superclass of a new S4 class. See the section on extending S3 classes below, and the examples.

See Methods for the details of method dispatch and inheritance.

Some S3 classes cannot be represented as an ordinary combination of S4 classes and superclasses, because objects from the S3 class can have a variable set of strings in the class. It is still possible to register such classes as S4 classes, but now the inheritance has to be verified for each object, and you must call setOldClass with argument test=TRUE once for each superclass.

For example, ordered factors always have the S3 class c("ordered", "factor"). This is proper behavior, and maps simply into two S4 classes, with "ordered" extending "factor".

But objects whose class attribute has "POSIXt" as the first string may have either (or neither) of "POSIXct" or "POSIXlt" as the second string. This behavior can be mapped into S4 classes but now to evaluate is(x, "POSIXlt"), for example, requires checking the S3 class attribute on each object. Supplying the test=TRUE argument to setOldClass causes an explicit test to be included in the class definitions. It’s never wrong to have this test, but since it adds significant overhead to methods defined for the inherited classes, you should only supply this argument if it's known that object-specific tests are needed.

The list .OldClassesList contains the old-style classes that are defined by the methods package. Each element of the list is a character vector, with multiple strings if inheritance is included. Each element of the list was passed to setOldClass when creating the methods package; therefore, these classes can be used in setMethod calls, with the inheritance as implied by the list.

Extending S3 classes

A call to setOldClass creates formal classes corresponding to S3 classes, allows these to be used as slots in other classes or in a signature in setMethod, and mimics the S3 inheritance.

In documentation for the initial implementation of S4 classes in R, users were warned against defining S4 classes that contained S3 classes, even if those had been registered. The warning was based mainly on two points. 1: The S3 behavior of the objects would fail because the S3 class would not be visible, for example, when S3 methods are dispatched. 2: Because S3 classes have no formal definition, nothing can be asserted in general about the S3 part of an object from such a class. (The warning was repeated as recently as the first reference below.)

Nevertheless, defining S4 classes to contain an S3 class and extend its behavior is attractive in many applications. The alternative is to be stuck with S3 programming, without the flexibility and security of formal class and method definitions.

Beginning with version 2.8.0, R provides support for extending registered S3 classes; that is, for new classes defined by a call to setClass in which the contains= argument includes an S3 class. See the examples below. The support is aimed primarily at providing the S3 class information for all classes that extend class oldClass, in particular by ensuring that all objects from such classes contain the S3 class in a special slot.
There are three different ways to indicate an extension to an existing S3 class: `setOldClass()`, `setClass()` and `setIs()`. In most cases, calling `setOldClass` is the best approach, but the alternatives may be preferred in the special circumstances described below.

Suppose "A" is any class extending "oldClass". then

```r
setOldClass(c("B", "A"))
```

creates a new class "B" whose S3 class concatenates "B" with `S3Class("A")`. The new class is a virtual class. If "A" was defined with known attribute/slots, then "B" has these slots also; therefore, you must believe that the corresponding S3 objects from class "B" do indeed have the claimed attributes. Notice that you can supply an S4 definition for the new class to specify additional attributes (as described in the next section.) The first alternative call produces a non-virtual class.

```r
setClass("B", contains = "A")
```

This creates a non-virtual class with the same slots and superclasses as class "A". However, class "B" is not included in the S3 class slot of the new class, unless you provide it explicitly in the prototype.

```r
setClass("B"); setIs("B", "A", ....)
```

This creates a virtual class that extends "A", but does not contain the slots of "A". The additional arguments to `setIs` should provide a coerce and replacement method. In order for the new class to inherit S3 methods, the coerce method must ensure that the class "A" object produced has a suitable S3 class. The only likely reason to prefer this third approach is that class "B" is not consistent with known attributes in class "A".

Beginning with version 2.9.0 of R, objects from a class extending an S3 class will be converted to the corresponding S3 class when being passed to an S3 method defined for that class (that is, for one of the strings in the S3 class attribute). This is intended to ensure, as far as possible, that such methods will work if they work for ordinary S3 objects. See `Classes` for details.

### S3 Classes with known attributes

A further specification of an S3 class can be made if the class is guaranteed to have some attributes of known class (where as with slots, “known” means that the attribute is an object of a specified class, or a subclass of that class).

In this case, the call to `setOldClass()` can supply an S4 class definition representing the known structure. Since S4 slots are implemented as attributes (largely for just this reason), the known attributes can be specified in the representation of the S4 class. The usual technique will be to create an S4 class with the desired structure, and then supply the class name or definition as the argument `S4Class` to `setOldClass()`.

See the definition of class "ts" in the examples below. The call to `setClass` to create the S4 class can use the same class name, as here, so long as the class definition is not sealed. In the example, we define "ts" as a vector structure with a numeric slot for "tsp". The validity of this definition relies on an assertion that all the S3 code for this class is consistent with that definition; specifically, that all "ts" objects will behave as vector structures and will have a numeric "tsp" attribute. We believe this to be true of all the base code in R, but as always with S3 classes, no guarantee is possible.

The S4 class definition can have virtual superclasses (as in the "ts" case) if the S3 class is asserted to behave consistently with these (in the example, time-series objects are asserted to be consistent with the `structure` class).

For another example, look at the S4 class definition for "data.frame". Be warned that failures of the S3 class to live up to its asserted behavior will usually go uncorrected, since S3 classes inherently have no definition, and the resulting invalid S4 objects can cause all sorts of grief. Many S3 classes are not candidates for known slots, either because the presence or class of
the attributes are not guaranteed (e.g., dimnames in arrays, although these are not even S3 classes),
or because the class uses named components of a list rather than attributes (e.g., "lm"). An attribute
that is sometimes missing cannot be represented as a slot, not even by pretending that it is present
with class "NULL", because attributes unlike slots can not have value NULL.

One irregularity that is usually tolerated, however, is to optionally add other attributes to those
guaranteed to exist (for example, "terms" in "data.frame" objects returned by `model.frame`).
As of version 2.8.0, validity checks by `validObject` ignore extra attributes; even if this check
is tightened in the future, classes extending S3 classes would likely be exempted because extra
attributes are so common.

Examples

```r
require(stats)
setOldClass(c("mlm", "lm"))
setGeneric("dfResidual", function(model)standardGeneric("dfResidual"))
setMethod("dfResidual", "lm", function(model)model$df.residual)

## dfResidual will work on mlm objects as well as lm objects
myData <- data.frame(time = 1:10, y = (1:10)^.5)
mylm <- lm(cbind(y, y^3) ~ time, myData)

showClass("data.frame") # to see the predefined S4 "oldClass"

## two examples extending S3 class "lm", class "xlm" directly
## and "ylm" indirectly
setClass("xlm", representation(eps = "numeric"), contains = "lm")
setClass("ylm", representation(header = "character"), contains = "xlm")

ymlm = new("ylm", mylm, header = "Example", eps = 0.)
## for more examples, see ?link[S3Class].
utils::str(.OldClassesList)
```

## Examples of S3 classes with guaranteed attributes
## an S3 class "stamped" with a vector and a "date" attribute
## Here is a generator function and an S3 print method.
## NOTE: it's essential that the generator checks the attribute classes

```r
stamped <- function(x, date = Sys.time()) {
  if(!inherits(date, "POSIXt"))
    stop("bad date argument")
  if(!is.vector(x))
    stop("x must be a vector")
  attr(x, "date") <- date
  class(x) <- "stamped"
}
```
Show an Object

Display the object, by printing, plotting or whatever suits its class. This function exists to be specialized by methods. The default method calls `showDefault`.

Formal methods for show will usually be invoked for automatic printing (see the details).

Usage

```r
show(object)
```
**show**

Arguments

- **object**: Any R object

Details

Objects from an S4 class (a class defined by a call to `setClass`) will be displayed automatically is if by a call to `show`. S4 objects that occur as attributes of S3 objects will also be displayed in this form; conversely, S3 objects encountered as slots in S4 objects will be printed using the S3 convention, as if by a call to `print`.

Methods defined for `show` will only be inherited by simple inheritance, since otherwise the method would not receive the complete, original object, with misleading results. See the `simpleInheritanceOnly` argument to `setGeneric` and the discussion in `setIs` for the general concept.

Value

`show` returns an invisible NULL.

See Also

- `showMethods` prints all the methods for one or more functions.

Examples

```r
## following the example shown in the setMethod documentation ...
setClass("track",
    representation(x="numeric", y="numeric"))
setClass("trackCurve",
    representation("track", smooth = "numeric"))

t1 <- new("track", x=1:20, y=(1:20)^2)
tc1 <- new("trackCurve", t1)

setMethod("show", "track",
    function(object)print(rbind(x = object$x, y=object$y))
)
## The method will now be used for automatic printing of t1

t1

  x  1  2  3  4  5  6  7  8  9 10 11 12
  y  1  4  9 16 25 36 49 64 81 100 121 144

## End(Not run)
## and also for tc1, an object of a class that extends "track"
tc1

  x  1  2  3  4  5  6  7  8  9 10 11 12
  y  1  4  9 16 25 36 49 64 81 100 121 144
```
**showMethods**

Show all the methods for the specified function(s)

**Description**

Show a summary of the methods for one or more generic functions, possibly restricted to those involving specified classes.

**Usage**

```r
showMethods(f = character(), where = toplevel(parent.frame()),
classes = NULL, includeDefs = FALSE,
inherited = !includeDefs,
showEmpty, printTo = stdout(), fdef)
```

**Arguments**

- **f**
  one or more function names. If omitted, all functions will be shown that match the other arguments.
  The argument can also be an expression that evaluates to a single generic function, in which case argument `fdef` is ignored. Providing an expression for the function allows examination of hidden or anonymous functions; see the example for `isDiagonal()`.

- **where**
  Where to find the generic function, if not supplied as an argument. When `f` is missing, or length 0, this also determines which generic functions to examine. If `where` is supplied, only the generic functions returned by `getGenerics(where)` are eligible for printing. If `where` is also missing, all the cached generic functions are considered.

- **classes**
  If argument `classes` is supplied, it is a vector of class names that restricts the displayed results to those methods whose signatures include one or more of those classes.

- **includeDefs**
  If `includeDefs` is TRUE, include the definitions of the individual methods in the printout.

- **inherited**
  Logical indicating if methods that have been found by inheritance, so far in the session, will be included and marked as inherited. Note that an inherited method will not usually appear until it has been used in this session. See `selectMethod` if you want to know what method would be dispatched for particular classes of arguments.

- **showEmpty**
  Logical indicating whether methods with no defined methods matching the other criteria should be shown at all. By default, TRUE if and only if argument `f` is not missing.

- **printTo**
  The connection on which the information will be shown; by default, on standard output.

- **fdef**
  Optionally, the generic function definition to use; if missing, one is found, looking in `where` if that is specified. See also comment in ‘Details’.
showMethods

Details
The name and package of the generic are followed by the list of signatures for which methods are currently defined, according to the criteria determined by the various arguments. Note that the package refers to the source of the generic function. Individual methods for that generic can come from other packages as well.

When more than one generic function is involved, either as specified or because f was missing, the functions are found and showMethods is recalled for each, including the generic as the argument fdef. In complicated situations, this can avoid some anomalous results.

Value
If printTo is FALSE, the character vector that would have been printed is returned; otherwise the value is the connection or filename, via invisible.

See Also
setMethod, and GenericFunctions for other tools involving methods; selectMethod will show you the method dispatched for a particular function and signature of classes for the arguments.

Examples
require(graphics)

## Assuming the methods for plot
## are set up as in the example of help(setMethod),
## print (without definitions) the methods that involve class "track":
showMethods("plot", classes = "track")
## Not run:
# Function "plot":
# x = ANY, y = track
# x = track, y = missing
# x = track, y = ANY

require("Matrix")
showMethods("%*%")# many!
  methods(class = "Matrix")# nothing
showMethods(class = "Matrix")# everything
showMethods(Matrix::isDiagonal) # a non-exported generic

## End(Not run)

not.there <- !any("package:stats4" == search())
if(not.there) library(stats4)
showMethods(classes = "mle")
if(not.there) detach("package:stats4")
signature-class  

*Class "signature" For Method Definitions*

**Description**

This class represents the mapping of some of the formal arguments of a function onto the corresponding classes. It is used for two slots in the MethodDefinition class.

**Objects from the Class**

Objects can be created by calls of the form `new("signature", functionDef, ...)`. The `functionDef` argument, if it is supplied as a function object, defines the formal names. The other arguments define the classes. More typically, the objects are created as side effects of defining methods. Either way, note that the classes are expected to be well defined, usually because the corresponding class definitions exist. See the comment on the package slot.

**Slots**

- `.Data`: Object of class "character" the class names.
- `names`: Object of class "character" the corresponding argument names.
- `package`: Object of class "character" the names of the packages corresponding to the class names. The combination of class name and package uniquely defines the class. In principle, the same class name could appear in more than one package, in which case the package information is required for the signature to be well defined.

**Extends**

Class "character", from data part. Class "vector", by class "character".

**Methods**

- `initialize signature(object = "signature")`: see the discussion of objects from the class, above.

**See Also**

class MethodDefinition for the use of this class.

*slot*  

*The Slots in an Object from a Formal Class*

**Description**

These functions return or set information about the individual slots in an object.
Usage

object@name
object@name <- value

slot(object, name)
slot(object, name, check = TRUE) <- value
.hasSlot(object, name)

slotNames(x)
getSlots(x)

Arguments

object
An object from a formally defined class.

name
The name of the slot. The operator takes a fixed name, which can be unquoted if it is syntactically a name in the language. A slot name can be any non-empty string, but if the name is not made up of letters, numbers, and ., it needs to be quoted (by backticks or single or double quotes).

In the case of the \texttt{set} function, \texttt{name} can be any expression that evaluates to a valid slot in the class definition. Generally, the only reason to use the functional form rather than the simpler operator is because the slot name has to be computed.

value
A new value for the named slot. The value must be valid for this slot in this object’s class.

check
In the replacement version of \texttt{set}, a flag. If \texttt{true}, check the assigned value for validity as the value of this slot. User’s coded should not set this to \texttt{false} in normal use, since the resulting object can be invalid.

\texttt{x}
either the name of a class (as character string), or a class definition. If given an argument that is neither a character string nor a class definition, \texttt{slotNames} (only) uses \texttt{class(x)} instead.

Details

The definition of the class specifies all slots directly and indirectly defined for that class. Each slot has a name and an associated class. Extracting a slot returns an object from that class. Setting a slot first coerces the value to the specified slot and then stores it.

Unlike general attributes, slots are not partially matched, and asking for (or trying to set) a slot with an invalid name for that class generates an error.

The \texttt{@} extraction operator and \texttt{slot} function themselves do no checking against the class definition, simply matching the name in the object itself. The replacement forms do check (except for \texttt{slot} in the case \texttt{check=FALSE}). So long as slots are set without cheating, the extracted slots will be valid.

Be aware that there are two ways to cheat, both to be avoided but with no guarantees. The obvious way is to assign a slot with \texttt{check=FALSE}. Also, slots in \texttt{R} are implemented as attributes, for the sake of some back compatibility. The current implementation does not prevent attributes being assigned, via \texttt{attr<-.}, and such assignments are not checked for legitimate slot names.

Note that the \texttt{"@"} operators for extraction and (since \texttt{R 3.0.0}) replacement are primitive and actually reside in the \texttt{base} package.

The replacement versions of \texttt{"@"} and \texttt{slot()} differ in the computations done to coerce the right side of the assignment to the declared class of the slot. Both verify that the value provided is from a
subclass of the declared slot class. The slot() version will go on to call the coerce method if there is one, in effect doing the computation as(value, slotClass, strict = FALSE). The "@" version just verifies the relation, leaving any coerce to be done later (e.g., when a relevant method is dispatched).

In most uses the result is equivalent, and the "@" version saves an extra function call, but if empirical evidence shows that a conversion is needed, either call as() before the replacement or use the replacement version of slot()

Value
The "@" operator and the slot function extract or replace the formally defined slots for the object.
Functions slotNames and getSlots return respectively the names of the slots and the classes associated with the slots in the specified class definition. Except for its extended interpretation of x (above), slotNames(x) is just names(getSlots(x)).

Examples

```
setClass("track", representation(x="numeric", y="numeric"))
myTrack <- new("track", x = -4:4, y = exp(-4:4))
slot(myTrack, "x")
slot(myTrack, "y") <- log(slot(myTrack, "y"))
utils::str(myTrack)

getSlots("track") # or
getSlots(getClass("track"))
slotNames(class(myTrack)) # is the same as
slotNames(myTrack)
```

StructureClasses

<table>
<thead>
<tr>
<th>Classes Corresponding to Basic Structures</th>
</tr>
</thead>
</table>

Description
The virtual class structure and classes that extend it are formal classes analogous to S language structures such as arrays and time-series.
Usage

```r
## The following class names can appear in method signatures,
## as the class in as() and is() expressions, and, except for
## the classes commented as VIRTUAL, in calls to new()

"matrix"
"array"
"ts"

"structure" ## VIRTUAL
```

Objects from the Classes

Objects can be created by calls of the form `new(Class, ...)`, where `Class` is the quoted name of the specific class (e.g., "matrix"), and the other arguments, if any, are interpreted as arguments to the corresponding function, e.g., to function `matrix()`. There is no particular advantage over calling those functions directly, unless you are writing software designed to work for multiple classes, perhaps with the class name and the arguments passed in.

Objects created from the classes "matrix" and "array" are unusual, to put it mildly, and have been for some time. Although they may appear to be objects from these classes, they do not have the internal structure of either an S3 or S4 class object. In particular, they have no "class" attribute and are not recognized as objects with classes (that is, both `is.object` and `isS4` will return `FALSE` for such objects). However, methods (both S4 and S3) can be defined for these pseudo-classes and new classes (both S4 and S3) can inherit from them.

That the objects still behave as if they came from the corresponding class (most of the time, anyway) results from special code recognizing such objects being built into the base code of R. For most purposes, treating the classes in the usual way will work, fortunately. One consequence of the special treatment is that these two classes `may` be used as the data part of an S4 class; for example, you can get away with `contains = "matrix"` in a call to `setGeneric` to create an S4 class that is a subclass of "matrix". There is no guarantee that everything will work perfectly, but a number of classes have been written in this form successfully.

Note that a class containing "matrix" or "array" will have a `.Data` slot with that class. This is the only use of `.Data` other than as a pseudo-class indicating the type of the object. In this case the type of the object will be the type of the contained matrix or array. See `Classes` for a general discussion.

The class "ts" is basically an S3 class that has been registered with S4, using the `setOldClass` mechanism. Versions of R through 2.7.0 treated this class as a pure S4 class, which was in principal a good idea, but in practice did not allow subclasses to be defined and had other intrinsic problems. (For example, setting the "tsp" parameters as a slot often fails because the built-in implementation does not allow the slot to be temporarily inconsistent with the length of the data. Also, the S4 class prevented the correct specification of the S3 inheritance for class "mts".)

Time-series objects, in contrast to matrices and arrays, have a valid S3 class, "ts", registered using an S4-style definition (see the documentation for `setOldClass` in the examples section for an abbreviated listing of how this is done. The S3 inheritance of "mts" in package `stats` is also registered. These classes, as well as "matrix" and "array" should be valid in most examples as superclasses for new S4 class definitions.

All of these classes have special S4 methods for `initialize` that accept the same arguments as the basic generator functions, `matrix`, `array`, and `ts`, in so far as possible. The limitation is that a class that has more than one non-virtual superclass must accept objects from that superclass in the call to `new`; therefore, a such a class (what is called a “mixin” in some languages) uses the default method for `initialize`, with no special arguments.
Extends

The specific classes all extend class "structure", directly, and class "vector", by class "structure".

Methods

coerce Methods are defined to coerce arbitrary objects to these classes, by calling the corresponding basic function, for example, `as(x, "matrix")` calls `as.matrix(x)`. If `strict = TRUE` in the call to `as()`, the method goes on to delete all other slots and attributes other than the `dim` and `dimnames`.

Ops Group methods (see, e.g., `S4groupGeneric`) are defined for combinations of structures and vectors (including special cases for array and matrix), implementing the concept of vector structures as in the reference. Essentially, structures combined with vectors retain the structure as long as the resulting object has the same length. Structures combined with other structures remove the structure, since there is no automatic way to determine what should happen to the slots defining the structure.

Note that these methods will be activated when a package is loaded containing a class that inherits from any of the structure classes or class "vector".

See Also

Class `nonStructure`, which enforces the alternative model, in which all slots are dropped if any math transformation or operation is applied to an object from a class extending one of the basic classes.

Examples

```r
showClass("structure")

## explore a bit :
showClass("ts")
(ts0 <- new("ts"))
str(ts0)

showMethods("Ops") # six methods from these classes, but maybe many more
```

testInheritedMethods Test for and Report about Selection of Inherited Methods

Description

A set of distinct inherited signatures is generated to test inheritance for all the methods of a specified generic function. If method selection is ambiguous for some of these, a summary of the ambiguities is attached to the returned object. This test should be performed by package authors before releasing a package.
Usage

testInheritedMethods(f, signatures, test = TRUE, virtual = FALSE,
        groupMethods = TRUE, where = .GlobalEnv)

Arguments

f
a generic function or the character string name of one. By default, all currently
defined subclasses of all the method signatures for this generic will be examined.
The other arguments are mainly options to modify which inheritance patterns
will be examined.

signatures
An optional set of subclass signatures to use instead of the relevant subclasses
computed by testInheritedMethods. See the Details for how this is done. This argument might be supplied after a call with test = FALSE, to test selection
in batches.

test
optional flag to control whether method selection is actually tested. If FALSE, returns just the list of relevant signatures for subclasses, without calling
selectMethod for each signature. If there are a very large number of signatures, you may want to collect the full list and then test them in batches.

virtual
should virtual classes be included in the relevant subclasses. Normally not, since
only the classes of actual arguments will trigger the inheritance calculation in a
call to the generic function. Including virtual classes may be useful if the class
has no current non-virtual subclasses but you anticipate your users may define
such classes in the future.

groupMethods
should methods for the group generic function be included?

where
the environment in which to look for class definitions. Nearly always, use the
default global environment after attaching all the packages with relevant meth-
ods and/or class definitions.

Details

The following description applies when the optional arguments are omitted, the usual case. First,
the defining signatures for all methods are computed by calls to findMethodSignatures. From
these all the known non-virtual subclasses are found for each class that appears in the signature of
some method. These subclasses are split into groups according to which class they inherit from,
and only one subclass from each group is retained (for each argument in the generic signature).
So if a method was defined with class "vector" for some argument, one actual vector class is
chosen arbitrarily. The case of "ANY" is dealt with specially, since all classes extend it. A dummy,
nonvirtual class, ",.Other", is used to correspond to all classes that have no superclasses among
those being tested.

All combinations of retained subclasses for the arguments in the generic signature are then com-
puted. Each row of the resulting matrix is a signature to be tested by a call to selectMethod. To
collect information on ambiguous selections, testInheritedMethods establishes a calling handler
for the special signal "ambiguousMethodSelection", by setting the corresponding option.

Value

An object of class "methodSelectionReport". The details of this class are currently subject to change. It has slots "target", "selected", "candidates", and "note", all referring to the am-
biguous cases (and so of length 0 if there were none). These slots are intended to be examined
by the programmer to detect and preferably fix ambiguous method selections. The object contains
in addition slots "generic", the name of the generic function, and "allSelections", giving the vector of labels for all the signatures tested.

References

Examples

```r
## if no other attached packages have methods for '+' or its group
## generic functions, this returns a 16 by 2 matrix of selection
## patterns (in R 2.9.0)
testInheritedMethods("+")
```

TraceClasses  Classes Used Internally to Control Tracing

Description

The classes described here are used by the R function `trace` to create versions of functions and methods including browser calls, etc., and also to `untrace` the same objects.

Usage

```r
### Objects from the following classes are generated
### by calling `trace()` on an object from the corresponding
### class without the "WithTrace" in the name.

"functionWithTrace"
"MethodDefinitionWithTrace"
"MethodWithNextWithTrace"
"genericFunctionWithTrace"
"groupGenericFunctionWithTrace"

### the following is a virtual class extended by each of the
### classes above

"traceable"
```

Objects from the Class

Objects will be created from these classes by calls to `trace`. (There is an `initialize` method for class "traceable", but you are unlikely to need it directly.)

Slots

- `.Data`: The data part, which will be "function" for class "functionWithTrace", and similarly for the other classes.
- `original`: Object of the original class; e.g., "function" for class "functionWithTrace".
**validObject**

**Extends**

Each of the classes extends the corresponding untraced class, from the data part; e.g., "functionWithTrace" extends "function". Each of the specific classes extends "traceable", directly, and class "VIRTUAL", by class "traceable".

**Methods**

The point of the specific classes is that objects generated from them, by function trace(), remain callable or dispatchable, in addition to their new trace information.

**See Also**

function trace

---

**validObject**

*Test the Validity of an Object*

**Description**

The validity of object related to its class definition is tested. If the object is valid, TRUE is returned; otherwise, either a vector of strings describing validity failures is returned, or an error is generated (according to whether test is TRUE). Optionally, all slots in the object can also be validated.

The function setValidity sets the validity method of a class (but more normally, this method will be supplied as the validity argument to setClass). The method should be a function of one object that returns TRUE or a description of the non-validity.

**Usage**

validObject(object, test = FALSE, complete = FALSE)

setValidity(Class, method, where = topoenv(parent.frame()) )

getValidity(ClassDef)

**Arguments**

<table>
<thead>
<tr>
<th>argument</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>any object, but not much will happen unless the object’s class has a formal definition.</td>
</tr>
<tr>
<td>test</td>
<td>logical; if TRUE and validity fails, the function returns a vector of strings describing the problems. If test is FALSE (the default) validity failure generates an error.</td>
</tr>
<tr>
<td>complete</td>
<td>logical; if TRUE, validity methods will be applied recursively to any of the slots that have such methods.</td>
</tr>
<tr>
<td>Class</td>
<td>the name or class definition of the class whose validity method is to be set.</td>
</tr>
<tr>
<td>ClassDef</td>
<td>a class definition object, as from getClassDef.</td>
</tr>
<tr>
<td>method</td>
<td>a validity method; that is, either NULL or a function of one argument (object). Like validObject, the function should return TRUE if the object is valid, and one or more descriptive strings if any problems are found. Unlike validObject, it should never generate an error.</td>
</tr>
</tbody>
</table>
validObject

where the modified class definition will be stored in this environment.

Note that validity methods do not have to check validity of superclasses: the logic of validObject ensures these tests are done once only. As a consequence, if one validity method wants to use another, it should extract and call the method from the other definition of the other class by calling getValidity(): it should not call validObject.

Details

Validity testing takes place 'bottom up': Optionally, if complete=TRUE, the validity of the object’s slots, if any, is tested. Then, in all cases, for each of the classes that this class extends (the 'superclasses'), the explicit validity method of that class is called, if one exists. Finally, the validity method of object’s class is called, if there is one.

Testing generally stops at the first stage of finding an error, except that all the slots will be examined even if a slot has failed its validity test.

The standard validity test (with complete=FALSE) is applied when an object is created via new with any optional arguments (without the extra arguments the result is just the class prototype object).

An attempt is made to fix up the definition of a validity method if its argument is not object.

Value

validObject returns TRUE if the object is valid. Otherwise a vector of strings describing problems found, except that if test is FALSE, validity failure generates an error, with the corresponding strings in the error message.

setClass; class classRepresentation.

Examples

setClass("track",
    representation(x="numeric", y = "numeric"))
t1 <- new("track", x=1:10, y=sort(stats::rnorm(10)))
## A valid "track" object has the same number of x, y values
validTrackObject <- function(object) {
    if(length(object$x) == length(object$y)) TRUE
    else paste("Unequal x,y lengths: ", length(object$x), ", ", length(object$y), sep="")
}
## assign the function as the validity method for the class
setValidity("track", validTrackObject)
## t1 should be a valid "track" object
validObject(t1)
## Now we do something bad

## This should generate an error
validObject

## Not run: try(validObject(t2))

setClass("trackCurve",
    representation("track", smooth = "numeric"))

## all superclass validity methods are used when validObject
## is called from initialize() with arguments, so this fails
## Not run: try(new("trackCurve", t2))

setClass("twoTrack", representation(t1 = "track", tr2 ="track"))

## validity tests are not applied recursively by default,
## so this object is created (invalidly)
tT <- new("twoTrack", tr2 = t2)

## A stricter test detects the problem
## Not run: try(validObject(tT, complete = TRUE))
Chapter 8

The parallel package

parallel-package Support for Parallel Computation

Description

Support for parallel computation, including random-number generation.

Details

This package is under development: a first version was released with R 2.14.0.

There is support for multiple RNG streams with the "L'Ecuyer-CMRG" RNG: see nextRNGStream.

It contains functionality derived from and pretty much equivalent to that contained in packages multicore (with some low-level functions renamed and not exported) and snow (for socket clusters only, but MPI and NWS clusters generated by snow are also supported). This package also provides makeForkCluster.

For a complete list of exported functions, use library(help = "parallel").

Author(s)

Brian Ripley, Luke Tierney and Simon Urbanek

Maintainer: R Core Team <R-core@r-project.org>

See Also

Parallel computation involves launching worker processes: functions psnice and pskill in package tools provide means to manage such processes.
clusterApply  

Apply Operations using Clusters

Description

These functions provide several ways to parallelize computations using a cluster.

Usage

clusterCall(cl = NULL, fun, ...)
clusterApply(cl = NULL, x, fun, ...)
clusterApplyLB(cl = NULL, x, fun, ...)
clusterEvalQ(cl = NULL, expr)
clusterExport(cl = NULL, varlist, envir = .GlobalEnv)
clusterMap(cl = NULL, fun, ..., MoreArgs = NULL, RECYCLE = TRUE,
          SIMPLIFY = FALSE, USE.NAMES = TRUE,
          .scheduling = c("static", "dynamic"))
clusterSplit(cl = NULL, seq)
parLapply(cl = NULL, X, fun, ...)
parSapply(cl = NULL, X, FUN, ..., simplify = TRUE,
          USE.NAMES = TRUE)
parApply(cl = NULL, X, MARGIN, FUN, ...)
parRapply(cl = NULL, x, FUN, ...)
parCapply(cl = NULL, x, FUN, ...)
parLapplyLB(cl = NULL, X, fun, ...)
parSapplyLB(cl = NULL, X, FUN, ..., simplify = TRUE,
            USE.NAMES = TRUE)

Arguments

cl     a cluster object, created by this package or by package snow. If NULL, use the registered default cluster.
fun, FUN  function or character string naming a function.
expr     expression to evaluate.
seq      vector to split.
varlist  character vector of names of objects to export.
envir    environment from which t export variables
x        a vector for clusterApply and clusterApplyLB, a matrix for parRapply and parCapply.
...      additional arguments to pass to fun or FUN: beware of partial matching to earlier arguments.
MoreArgs additional arguments for fun.
RECYCLE  logical; if true shorter arguments are recycled.
X        A vector (atomic or list) for parLapply and parSapply, an array for parApply.
MARGIN   vector specifying the dimensions to use.
clusterApply

simplify, USE.NAMES
logical; see sapply.
SIMPLIFY logical; see mapply.
.scheduling should tasks be statically allocated to nodes or dynamic load-balancing used?

Details

clusterCall calls a function fun with identical arguments ... on each node.
clusterEvalQ evaluates a literal expression on each cluster node. It is a parallel version of evalq, and is a convenience function invoking clusterCall.
clusterApply calls fun on the first node with arguments seq[[1]] and ..., on the second node with seq[[2]] and ..., and so on, recycling nodes as needed.
clusterApplyLB is a load balancing version of clusterApply. If the length p of seq is not greater than the number of nodes n, then a job is sent to p nodes. Otherwise the first n jobs are placed in order on the n nodes. When the first job completes, the next job is placed on the node that has become free; this continues until all jobs are complete. Using clusterApplyLB can result in better cluster utilization than using clusterApply, but increased communication can reduce performance. Furthermore, the node that executes a particular job is non-deterministic.
clusterMap is a multi-argument version of clusterApply, analogous to mapply and Map. If RECYCLE is true shorter arguments are recycled (and either none or all must be of length zero); otherwise, the result length is the length of the shortest argument. Nodes are recycled if the length of the result is greater than the number of nodes. (mapply always uses RECYCLE = TRUE, and has argument SIMPLIFY = TRUE. Map always uses RECYCLE = TRUE.)
clusterExport assigns the values on the master R process of the variables named in varlist to variables of the same names in the global environment (aka 'workspace') of each node. The environment on the master from which variables are exported defaults to the global environment.
clusterSplit splits seq into a consecutive piece for each cluster and returns the result as a list with length equal to the number of nodes. Currently the pieces are chosen to be close to equal in length: the computation is done on the master.
parApply, parSapply, and parApply are parallel versions of lapply, sapply and apply. parApplyLB, parSapplyLB are load-balancing versions, intended for use when applying FUN to different elements of X takes quite variable amounts of time, and either the function is deterministic or reproducible results are not required. parRapply and parCapply are parallel row and column apply functions for a matrix x; they may be slightly more efficient than parApply but do less post-processing of the result.

Value

For clusterCall, clusterEvalQ and clusterSplit, a list with one element per node.
For clusterApply and clusterApplyLB, a list the same length as seq.
clusterMap follows mapply.
clusterExport returns nothing.
parApply returns a list the length of X.
parSapply and parApply follow sapply and apply respectively.
parRapply and parCapply always return a vector. If FUN always returns a scalar result this will be of length the number of rows or columns: otherwise it will be the concatenation of the returned values.
An error is signalled on the master if any of the workers produces an error.
Note

These functions are almost identical to those in package snow.

Two exceptions: parLapply has argument X not x for consistency with lapply, and parSapply has been updated to match sapply.

Luke Tierney and R Core.

Derived from the snow package.

Examples

```r
## Use option cl.cores to choose an appropriate cluster size.
cl <- makeCluster(getOption("cl.cores", 2))

clusterApply(cl, 1:2, get("+"), 3)
xx <- 1
clusterExport(cl, "xx")
clusterCall(cl, function(y) xx + y, 2)

## Use clusterMap like an maply example
clusterMap(cl, function(x, y) seq_len(x) + y,
          c(a = 1, b = 2, c = 3), c(A = 10, B = 0, C = -10))

parsSapply(cl, 1:20, get("+"), 3)

## A bootstrapping example, which can be done in many ways:
clusterEvalQ(cl, {
    ## set up each worker. Could also use clusterExport()
    library(boot)
    cd4.rg <- function(data, mle) MASS::mvrnorm(nrow(data), mle$m, mle$v)
    cd4.mle <- list(m = colMeans(cd4), v = var(cd4))
    NULL
})
res <- clusterEvalQ(cl, boot(cd4, corr, R = 100,
          sim = "parametric", run.gen = cd4.rg, mle = cd4.mle))
library(boot)

for.ci <- do.call(c, res)
boot.ci(cd4.boot, type = c("norm", "basic", "perc"),
       conf = 0.9, h = atanh, hinv = tanh)
stopCluster(cl)
```

## or

```r
library(boot)
run1 <- function(...) {
    library(boot)
    cd4.rg <- function(data, mle) MASS::mvrnorm(nrow(data), mle$m, mle$v)
    cd4.mle <- list(m = colMeans(cd4), v = var(cd4))
    boot(cd4, corr, R = 500, sim = "parametric",
         run.gen = cd4.rg, mle = cd4.mle)
}

cl <- makeCluster(mc <- getOption("cl.cores", 2))
## to make this reproducible
clusterSetRNGStream(cl, 123)
```
detectCores

**Detect the Number of CPU Cores**

**Description**

Attempt to detect the number of CPU cores on the current host.

**Usage**

```r
detectCores(all.tests = FALSE, logical = FALSE)
```

**Arguments**

- `all.tests`: Logical: if true apply all known tests.
- `logical`: Logical: if possible, use the number of physical CPUs/cores (if FALSE) or logical CPUs (if TRUE).

**Details**

This attempts to detect the number of CPU cores in the current machine.

It has methods to do so for Linux, OS X, FreeBSD, Solaris, Irix and Windows. `detectCores(TRUE)` could be tried on other Unix-alike systems.

**Value**

An integer, NA if the answer is unknown.

Exactly what this represents is OS-dependent: where possible by default it represents physical cores and not logical (e.g., hyperthreaded) CPUs.

On Windows the default is the number of logical CPUs.

Currently `logical` makes a difference on Sparc Solaris: there `logical = FALSE` returns the number of physical cores and `logical = TRUE` returns the number of available hardware threads. (Some Sparc CPUs which do have multiple cores per CPU, others have multiple threads per core and some have both.) For example, the UltraSparc T2 CPU in the CRAN check server is a single physical CPU with 8 cores, and each core supports 8 hardware threads. So `detectCores(logical = FALSE)` returns 8, and `detectCores(logical = TRUE)` returns 64.

Where virtual machines are in use, one would hope that the result represents the number of CPUs available (or potentially available) to that particular VM.

**Note**

This is not suitable for use directly for the `mc.cores` argument of `mclapply` nor specifying the number of cores in `makeCluster`. First because it may return NA, and second because it does not give the number of *allowed* cores.
makeCluster

Examples

detectCores()
detectCores(logical = TRUE)

makeCluster Create a Parallel Socket Cluster

Description

Creates a set of copies of R running in parallel and communicating over sockets.

Usage

makeCluster(spec, type, ...)
makePSOCKcluster(names, ...)
makeForkCluster(nnodes =getOption("mc.cores", 2L), ...)
stopCluster(cl = NULL)
setDefaultCluster(cl = NULL)

Arguments

spec A specification appropriate to the type of cluster.
names Either a character vector of host names on which to run the worker copies of R, or a positive integer (in which case that number of copies is run on 'localhost').
nnodes The number of nodes to be forked.
type One of the supported types: see 'Details'.
... Options to be passed to the function spawning the workers. See 'Details'.
cl an object of class "cluster".

Details

makeCluster creates a cluster of one of the supported types. The default type, "PSOCK", calls makePSOCKcluster. Type "FORK" calls makeForkCluster. Other types are passed to package snow.

makePSOCKcluster is an enhanced version of makeSOCKcluster in package snow. It runs Rscript on the specified host(s) to set up a worker process which listens on a socket for expressions to evaluate, and returns the results (as serialized objects).

makeForkCluster is merely a stub on Windows. On Unix-alike platforms it creates the worker process by forking.

The workers are most often running on the same host as the master, when no options need be set. Several options are supported (mainly for makePSOCKcluster):
makeCluster

master  The host name of the master, as known to the workers. This may not be the same as it is known to the master, and on private subnets it may be necessary to specify this as a numeric IP address. For example, OS X is likely to detect a machine as ‘somedename.local’, a name known only to itself.

group The port number for the socket connection, default taken from the environment variable R_PARALLEL_PORT, then a randomly chosen port in the range 11000:11999.

timeout The timeout in seconds for that port. Default 30 days (and the POSIX standard only requires values up to 31 days to be supported).

outfile Where to direct the stdout and stderr connection output from the workers. “” indicates no redirection (which may only be useful for workers on the local machine). Defaults to ‘/dev/null’ (‘nul:’ on Windows). The other possibility is a file path on the worker’s host. Files will be opened in append mode, as all workers log to the same file.

homogeneous Logical. Are all the hosts running identical setups, so Rscript can be launched using the same path on each? Otherwise Rscript has to be in the default path on the workers.

rscript The path to Rscript on the workers, used if homogeneous is true. Defaults to the full path on the master.

rscript_args Character vector of additional arguments for Rscript such as ‘--no-environ’.

renice A numerical ‘niceness’ to set for the worker processes, e.g. 15 for a low priority. OS-dependent: see psnice for details.

rshcmd The command to be run on the master to launch a process on another host. Defaults to ssh.

user The user name to be used when communicating with another host.

manual Logical. If true the workers will need to be run manually.

methods Logical. If true (default) the workers will load the methods package: not loading it saves ca 30% of the startup CPU time of the cluster.

useXDR Logical. If true (default) serialization will use XDR; where large amounts of data are to be transferred and all the nodes are little-endian, communication may be substantially faster if this is set to false.

Function makeForkCluster creates a socket cluster by forking (and hence is not available on Windows). It supports options port, timeout and outfile, and always uses useXDR = FALSE.

It is good practice to shut down the workers by calling stopCluster: however the workers will terminate themselves once the socket on which they are listening for commands becomes unavailable, which it should if the master R session is completed (or its process dies).

Function setDefaultCluster registers a cluster as the default one for the current session. Using setDefaultCluster(NULL) removes the registered cluster, as does stopping that cluster.

Value

An object of class c("SOCKcluster", "cluster").

mcaffinity

Get or Set CPU Affinity Mask of the Current Process

Description

mcaffinity retrieves or sets the CPU affinity mask of the current process, i.e., the set of CPUs the process is allowed to be run on. (CPU here means logical CPU which can be CPU, core or hyperthread unit.)

Usage

mcaffinity(affinity = NULL)

Arguments

affinity specification of the CPUs to lock this process to (numeric vector) or NULL if no change is requested

Details

mcaffinity can be used to obtain (affinity = NULL) or set the CPU affinity mask of the current process. The affinity mask is a list of integer CPU identifiers (starting from 1) that this process is allowed to run on. Not all systems provide user access to the process CPU affinity, in cases where no support is present at all mcaffinity() will return NULL. Some systems may take into account only the number of CPUs present in the mask.

Typically, it is legal to specify larger set than the number of logical CPUs (but at most as many as the OS can handle) and the system will return back the actually present set.

Value

NULL if CPU affinity is not supported by the system or an integer vector with the set of CPUs in the active affinity mask for this process (this may be different than affinity).

mcparallel
Description

These are low-level support functions for the forking approach.
They are not available on Windows, and not exported from the namespace.

Usage

children(select)
readChild(child)
readChildren(timeout = 0)
selectChildren(children = NULL, timeout = 0)
sendChildStdin(child, what)
sendMaster(what)

mckill(process, signal = 2L)

Arguments

select if omitted, all active children are returned, otherwise select should be a list of processes and only those from the list that are active will be returned.
child child process (object of the class "childProcess") or a process ID (pid). See also 'Details'.
timeout timeout (in seconds, fractions supported) to wait for a response before giving up.
children list of child processes or a single child process object or a vector of process IDs or NULL. If NULL behaves as if all currently known children were supplied.
what For sendChildStdin:
Character or raw vector. In the former case elements are collapsed using the newline character. (But no trailing newline is added at the end!)
For sendMaster:
Data to send to the master process. If what is not a raw vector, it will be serialized into a raw vector. Do NOT send an empty raw vector – that is reserved for internal use.
process process (object of the class process) or a process ID (pid)
signal integer: signal to send. Values of 2 (SIGINT), 9 (SIGKILL) and 15 (SIGTERM) are pretty much portable, but for maximal portability use tools::SIGTERM and so on.

Details

children returns currently active children.
readChild reads data from a given child process.
selectChildren checks children for available data.
readChildren checks all children for available data and reads from the first child that has available data.
sendChildStdin sends a string (or data) to one or more child’s standard input. Note that if the master session was interactive, it will also be echoed on the standard output of the master process (unless disabled). The function is vector-compatible, so you can specify child as a list or a vector of process IDs.

sendMaster sends data from the child to the master process.

mckill sends a signal to a child process: it is equivalent to pskill in package tools.

Value

children returns a (possibly empty) list of objects of class "process", the process ID.

readChild and readChildren return a raw vector with a "pid" attribute if data were available, an integer vector of length one with the process ID if a child terminated or NULL if the child no longer exists (no children at all for readChildren).

selectChildren returns TRUE is the timeout was reached, FALSE if an error occurred (e.g., if the master process was interrupted) or an integer vector of process IDs with children that have data available, or NULL if there are no children.

sendChildStdin returns a vector of TRUE values (one for each member of child) or throws an error.

sendMaster returns TRUE or throws an error.

mckill returns TRUE.

Warning

This is a very low-level API for expert use only.

mccollect(p)[[1]]

## End(Not run)
```
mcfork

Fork a Copy of the Current R Process

Description

These are low-level functions, not available on Windows, and not exported from the namespace.
mcfork creates a new child process as a copy of the current R process.
mcexit closes the current child process, informing the master process as necessary.

Usage

mcfork(estranged = FALSE)
mcexit(exit.code = 0L, send = NULL)

Arguments

estranged logical, if TRUE then the new process has no ties to the parent process, will not show in the list of children and will not be killed on exit.
exit.code process exit code. By convention 0L signifies a clean exit, 1L an error.
send if not NULL send this data before exiting (equivalent to using sendMaster).

Details

The mcfork function provides an interface to the fork system call. In addition it sets up a pipe between the master and child process that can be used to send data from the child process to the master (see sendMaster) and child’s ‘stdin’ is re-mapped to another pipe held by the master process (see sendChildStdin).

If you are not familiar with the fork system call, do not use this function directly as it leads to very complex inter-process interactions amongst the R processes involved.

In a nutshell fork spawns a copy (child) of the current process, that can work in parallel to the master (parent) process. At the point of forking both processes share exactly the same state including the workspace, global options, loaded packages etc. Forking is relatively cheap in modern operating systems and no real copy of the used memory is created, instead both processes share the same memory and only modified parts are copied. This makes mcfork an ideal tool for parallel processing since there is no need to setup the parallel working environment, data and code is shared automatically from the start.

mcexit is to be run in the child process. It sends send to the master (unless NULL) and then shuts down the child process. The child can also be shut down by sending it the signal SIGUSR1, as is done by the unexported function parallel::rmChild.

Value

mcfork returns an object of the class "childProcess" to the master and of class "masterProcess" to the child: both the classes inherit from class "process". If estranged is set to TRUE then the child process will be of the class "estrangedProcess" and cannot communicate with the master process nor will it show up on the list of children. These are lists with components pid (the process id of the other process) and a vector fd of the two file descriptor numbers for ends in the current process of the inter-process pipes.
mcexit never returns.
GUI/embedded environments

It is **strongly discouraged** to use `mcfork` and the higher-level functions which rely on it (e.g., `mcparallel`, `mclapply` and `pvec`) in GUI or embedded environments, because it leads to several processes sharing the same GUI which will likely cause chaos (and possibly crashes). Child processes should never use on-screen graphics devices. Some precautions have been taken to make this usable in R.app on OS X, but users of third-party front-ends should consult their documentation.

This can also apply to other connections (e.g., to an X server) created before forking, and to files opened by e.g. graphics devices.

Note that `tcltk` counts as a GUI for these purposes since Tcl runs an event loop. That event loop is inhibited in a child process but there could still be problems with Tk graphical connections.

**Warning**

This is a very low-level API for expert use only.

## This will work when run as an example, but not when pasted in.
p <- parallel::mcfork()
if (inherits(p, "masterProcess")) {
  cat("I'm a child! ", Sys.getpid(), "\n")
  parallel::mcexit("I was a child")
} else {
  cat("I'm the master\n")
  unserialize(parallel::readChildren(1.5))
}
```

---

**mclapply**  
*Parallel Versions of lapply and mapply using Forking*

**Description**

`mclapply` is a parallelized version of `lapply`, it returns a list of the same length as `X`, each element of which is the result of applying `FUN` to the corresponding element of `X`.

It relies on forking and hence is not available on Windows unless `mc.cores = 1`.

`mcmapply` is a parallelized version of `mapply`, and `mcMap` corresponds to `Map`. 
Usage

mclapply(X, FUN, ..., 
mc.preschedule = TRUE, mc.set.seed = TRUE, 
mc.silent = FALSE, mc.cores = getOption("mc.cores", 2L), 
mc.cleanup = TRUE, mc.allow.recursive = TRUE)

mcmapply(FUN, ..., 
MoreArgs = NULL, SIMPLIFY = TRUE, USE.NAMES = TRUE, 
mc.preschedule = TRUE, mc.set.seed = TRUE, 
mc.silent = FALSE, mc.cores = getOption("mc.cores", 2L), 
mc.cleanup = TRUE)

mcMap(f, ...)

Arguments

X a vector (atomic or list) or an expressions vector. Other objects (including 
classed objects) will be coerced by as.list.
FUN the function to be applied to (mclapply) each element of X or (mcmapply) in 
parallel to ....
f the function to be applied in parallel to ....
... For mclapply, optional arguments to FUN. For mcmapply and mcMap, vector or 
list inputs: see mapply.
MoreArgs, SIMPLIFY, USE.NAMES
see mapply.
mc.preschedule if set to TRUE then the computation is first divided to (at most) as many jobs are 
there are cores and then the jobs are started, each job possibly covering more 
than one value. If set to FALSE then one job is forked for each value of X. The 
former is better for short computations or large number of values in X, the latter 
is better for jobs that have high variance of completion time and not too many 
values of X compared to mc.cores.
mc.set.seed See mcpparallel.
mc.silent if set to TRUE then all output on ‘stdout’ will be suppressed for all parallel 
processes forked (‘stderr’ is not affected).
mc.cores The number of cores to use, i.e. at most how many child processes will be run 
simultaneously. The option is initialized from environment variable MC_CORES 
if set. Must be at least one, and parallelization requires at least two cores.
mc.cleanup if set to TRUE then all children that have been forked by this function will be 
killed (by sending SIGTERM) before this function returns. Under normal cir-
cumstances mclapply waits for the children to deliver results, so this option 
usually has only effect when mclapply is interrupted. If set to FALSE then child 
processes are collected, but not forcefully terminated. As a special case this 
argument can be set to the number of the signal that should be used to kill the 
children instead of SIGTERM.
mc.allow.recursive 
Unless true, calling mclapply in a child process will use the child and not fork 
again.
Details

`mclapply` is a parallelized version of `lapply`, provided `mc.cores > 1`; for `mc.cores == 1` it simply calls `lapply`. By default (`mc.preschedule = TRUE`) the input `x` is split into as many parts as there are cores (currently the values are spread across the cores sequentially, i.e. first value to core 1, second to core 2, ...(core + 1)-th value to core 1 etc.) and then one process is forked to each core and the results are collected.

Without prescheduling, a separate job is forked for each value of `x`. To ensure that no more than `mc.cores` jobs are running at once, once that number has been forked the master process waits for a child to complete before the next fork.

Due to the parallel nature of the execution random numbers are not sequential (in the random number sequence) as they would be when using `lapply`. They are sequential for each forked process, but not all jobs as a whole. See `mcparallel` or the package’s vignette for ways to make the results reproducible with `mc.preschedule = TRUE`.

Note: the number of file descriptors (and processes) is usually limited by the operating system, so you may have trouble using more than 100 cores or so (see `ulimit -n` or similar in your OS documentation) unless you raise the limit of permissible open file descriptors (fork will fail with error "unable to create a pipe").

Value

For `mclapply`, a list of the same length as `x` and named by `x`.

For `mcmaply`, a list, vector or array: see `mapply`.

For `mcMap`, a list.

Each forked process runs its job inside `try(..., silent = TRUE)` so if errors occur they will be stored as class "try-error" objects in the return value and a warning will be given. Note that the job will typically involve more than one value of `x` and hence a "try-error" object will be returned for all the values involved in the failure, even if not all of them failed.

Warning

It is strongly discouraged to use these functions in GUI or embedded environments, because it leads to several processes sharing the same GUI which will likely cause chaos (and possibly crashes). Child processes should never use on-screen graphics devices.

Some precautions have been taken to make this usable in R.app on OS X, but users of third-party front-ends should consult their documentation.

Note that `tcltk` counts as a GUI for these purposes since Tcl runs an event loop. That event loop is inhibited in a child process but there could still be problems with Tk graphical connections.

mcparallel

Evaluate an R Expression Asynchronously in a Separate Process

Description

These functions are based on forking and so are not available on Windows.
mcparallel starts a parallel R process which evaluates the given expression.
mcollect collects results from one or more parallel processes.

Usage

mcparallel(expr, name, mc.set.seed = TRUE, silent = FALSE,
          mc.affinity = NULL, mc.interactive = FALSE,
          detached = FALSE)
mcollect(jobs, wait = TRUE, timeout = 0, intermediate = FALSE)

Arguments

expr expression to evaluate (do not use any on-screen devices or GUI elements in this
code).
name an optional name (character vector of length one) that can be associated with the
job.
mc.set.seed logical: see section ‘Random numbers’.
silent if set to TRUE then all output on stdout will be suppressed (stderr is not affected).
mc.affinity either a numeric vector specifying CPUs to restrict the child process to (1-based)
or NULL to not modify the CPU affinity
mc.interactive logical, if TRUE or FALSE then the child process will be set as interactive or non-
interactive respectively. If NA then the child process will inherit the interactive
flag from the parent.
mcparallel

detached logical, if TRUE then the job is detached from the current session and cannot deliver any results back - it is used for the code side-effect only.

jobs list of jobs (or a single job) to collect results for. Alternatively jobs can also be an integer vector of process IDs. If omitted collect will wait for all currently existing children.

wait if set to FALSE it checks for any results that are available within timeout seconds from now, otherwise it waits for all specified jobs to finish.

timeout timeout (in seconds) to check for job results – applies only if wait is FALSE.

intermediate FALSE or a function which will be called while collect waits for results. The function will be called with one parameter which is the list of results received so far.

Details

mcparallel evaluates the expr expression in parallel to the current R process. Everything is shared read-only (or in fact copy-on-write) between the parallel process and the current process, i.e. no side-effects of the expression affect the main process. The result of the parallel execution can be collected using mccollect function.

mccollect function collects any available results from parallel jobs (or in fact any child process). If wait is TRUE then collect waits for all specified jobs to finish before returning a list containing the last reported result for each job. If wait is FALSE then mccollect merely checks for any results available at the moment and will not wait for jobs to finish. If jobs is specified, jobs not listed there will not be affected or acted upon.

Note: If expr uses low-level multicore functions such as sendMaster a single job can deliver results multiple times and it is the responsibility of the user to interpret them correctly. mccollect will return NULL for a terminating job that has sent its results already after which the job is no longer available.

The mc.affinity parameter can be used to try to restrict the child process to specific CPUs. The availability and the extent of this feature is system-dependent (e.g., some systems will only consider the CPU count, others will ignore it completely).

Value

mcparallel returns an object of the class "parallelJob" which inherits from "childProcess" (see the 'Value' section of the help for mcfork). If argument name was supplied this will have an additional component name.

mccollect returns any results that are available in a list. The results will have the same order as the specified jobs. If there are multiple jobs and a job has a name it will be used to name the result, otherwise its process ID will be used. If none of the specified children are still running, it returns NULL.

Random numbers

If mc.set.seed = FALSE, the child process has the same initial random number generator (RNG) state as the current R session. If the RNG has been used (or .Random.seed was restored from a saved workspace), the child will start drawing random numbers at the same point as the current session. If the RNG has not yet been used, the child will set a seed based on the time and process ID when it first uses the RNG: this is pretty much guaranteed to give a different random-number stream from the current session and any other child process.

The behaviour with mc.set.seed = TRUE is different only if RNGkind("L'Ecuyer-CMRG") has been selected. Then each time a child is forked it is given the next stream (see nextRNGStream).
So if you select that generator, set a seed and call `mc.reset.stream` just before the first use of `mcparallel` the results of simulations will be reproducible provided the same tasks are given to the first, second, ...forked process.

**Note**

Package `multicore` also exported functions `collect` and `parallel`. These names are easily masked (for example package `lattice` also has a function `parallel`) and they are not supplied in this package.

**Author(s)**

Simon Urbanek and R Core.

Derived from the `multicore` package (but with different handling of the RNG stream).

**See Also**

`pvec, mclapply`

**Examples**

```r
p <- mcparallel(1:10)
q <- mcparallel(1:20)
# wait for both jobs to finish and collect all results
res <- mccollect(list(p, q))

p <- mcparallel(1:10)
mccollect(p, wait = FALSE, 10) # will retrieve the result (since it's fast)
mccollect(p, wait = FALSE)    # will signal the job as terminating
mccollect(p, wait = FALSE)    # there is no longer such a job

# a naive parallel lapply can be created using mcparallel alone:
jobs <- lapply(1:10, function(x) mcparallel(rnorm(x), name = x))
mccollect(jobs)
```

**Description**

`pvec` parallelizes the execution of a function on vector elements by splitting the vector and submitting each part to one core. The function must be a vectorized map, i.e. it takes a vector input and creates a vector output of exactly the same length as the input which doesn’t depend on the partition of the vector.

It relies on forking and hence is not available on Windows unless `mc.cores = 1`.

**Usage**

```r
pvec(v, FUN, ..., mc.set.seed = TRUE, mc.silent = FALSE,
     mc.cores =getOption("mc.cores", 2L), mc.cleanup = TRUE)
```
Arguments

\[ v \] vector to operate on
\[ \text{FUN} \] function to call on each part of the vector
\[ \ldots \] any further arguments passed to \text{FUN} after the vector
\text{mc.set.seed} \quad \text{See mcpparallel.}
\text{mc.silent} \quad \text{if set to TRUE then all output on \texttt{stdout} will be suppressed for all parallel processes forked (\texttt{stderr} is not affected).}
\text{mc.cores} \quad \text{The number of cores to use, i.e. at most how many child processes will be run simultaneously. Must be at least one, and at least two for parallel operation. The option is initialized from environment variable \texttt{MC_CORES} if set.}
\text{mc.cleanup} \quad \text{See the description of this argument in mclapply.}

Details

\textit{pvec} parallelizes \textit{FUN}(x, \ldots) where \textit{FUN} is a function that returns a vector of the same length as \textit{x}. \textit{FUN} must also be pure (i.e., without side-effects) since side-effects are not collected from the parallel processes. The vector is split into nearly identically sized subvectors on which \textit{FUN} is run. Although it is in principle possible to use functions that are not necessarily maps, the interpretation would be case-specific as the splitting is in theory arbitrary (a warning is given in such cases).

The major difference between \textit{pvec} and \textit{mclapply} is that \textit{mclapply} will run \textit{FUN} on each element separately whereas \textit{pvec} assumes that \( c(\text{FUN}(x[1]), \text{FUN}(x[2])) \) is equivalent to \textit{FUN}(x[1:2]) and thus will split into as many calls to \textit{FUN} as there are cores (or elements, if fewer), each handling a subset vector. This makes it more efficient than \textit{mclapply} but requires the above assumption on \textit{FUN}.

If \textit{mc.cores} \( \geq 1 \) this evaluates \textit{FUN}(v, \ldots) in the current process.

Value

The result of the computation – in a successful case it should be of the same length as \textit{v}. If an error occurred or the function was not a map the result may be shorter or longer, and a warning is given.

Note

Due to the nature of the parallelization, error handling does not follow the usual rules since errors will be returned as strings and results from killed child processes will show up simply as nonexistent data. Therefore it is the responsibility of the user to check the length of the result to make sure it is of the correct size. \textit{pvec} raises a warning if that is the case since it does not know whether such an outcome is intentional or not.

See \textit{mcfork} for the inadvisability of using this with GUI front-ends.

Examples

```r
x <- pvec(1:1000, sqrt)
stopifnot(all(x == sqrt(1:1000)))

# One use is to convert date strings to unix time in large datasets
# as that is a relatively slow operation.
# So let's get some random dates first
# (A small test only with 2 cores: set options("mc.cores")
# and increase N for a larger-scale test.)
N <- 1e5
dates <- sprintf('%d-%02d-%02d', as.integer(2000+rnorm(N)),
    as.integer(runif(N, 1, 12)), as.integer(runif(N, 1, 28)))

system.time(a <- as.POSIXct(dates))

# But specifying the format is faster
system.time(a <- as.POSIXct(dates, format = "%Y-%m-%d"))

# pvec ought to be faster, but system overhead can be high
system.time(b <- pvec(dates, as.POSIXct, format = "%Y-%m-%d"))
stopifnot(all(a == b))

# using mclapply for this would much slower because each value
# will require a separate call to as.POSIXct()
# as lapply(dates, as.POSIXct) does
system.time(c <- unlist(mclapply(dates, as.POSIXct, format = "%Y-%m-%d")))
stopifnot(all(a == c))
```

RNGstreams

Implementation of Pierre L’Ecuyer’s RngStreams

Description

This is an R re-implementation of Pierre L’Ecuyer’s ‘RngStreams’ multiple streams of pseudo-random numbers.

Usage

```r
nextRNGStream(seed)
nextRNGSubStream(seed)
clusterSetRNGStream(cl = NULL, iseed)
mc.reset.stream()
```

Arguments

- `seed` An integer vector of length 7 as given by .Random.seed when the
  ‘"L’Ecuyer-CMRG’’ RNG is in use. See RNG for the valid values.
- `cl` A cluster from this package or package snow, or (if NULL) the registered cluster.
- `iseed` An integer to be supplied to set.seed, or NULL not to set reproducible seeds.
The ‘RngStream’ interface works with (potentially) multiple streams of pseudo-random numbers: this is particularly suitable for working with parallel computations since each task can be assigned a separate RNG stream.

This uses as its underlying generator RNGkind("L’Ecuyer-CMRG"), of L’Ecuyer (1999), which has a seed vector of 6 (signed) integers and a period of around $2^{191}$. Each ‘stream’ is a subsequence of the period of length $2^{127}$ which is in turn divided into ‘substreams’ of length $2^{76}$.

The idea of L’Ecuyer et al (2002) is to use a separate stream for each of the parallel computations (which ensures that the random numbers generated never get into sync) and the parallel computations can themselves use substreams if required. The original interface stores the original seed of the first stream, the original seed of the current stream and the current seed: this could be implemented in R, but it is as easy to work by saving the relevant values of .Random.seed: see the examples.

clusterSetRNGStream selects the "L’Ecuyer-CMRG" RNG and then distributes streams to the members of a cluster, optionally setting the seed of the streams by set.seed(iseed) (otherwise they are set from the current seed of the master process: after selecting the L’Ecuyer generator).

Calling mc.reset.stream() after setting the L’Ecuyer random number generator and seed makes runs from mcapply(mclapply, set.seed = TRUE) reproducible. This is done internally in mclapply and pvec. (Note that it does not set the seed in the master process, so does not affect the fallback-to-serial versions of these functions.)

Value

For nextRNGStream and nextRNGSubStream, a value which can be assigned to .Random.seed.

Note

Interfaces to L’Ecuyer’s C code are available in CRAN packages rlecuyer and rstream.

nextRNGSubStream(s)

splitIndices Divide Tasks for Distribution in a Cluster

Description
This divides up 1:nx into ncl lists of approximately equal size, as a way to allocate tasks to nodes in a cluster.

It is mainly for internal use, but some package authors have found it useful.

Usage
splitIndices(nx, ncl)

Arguments
nx Number of tasks.
ncl Number of cluster nodes.

Value
A list of length ncl, each element being an integer vector.

Examples
splitIndices(20, 3)
splitIndices
Chapter 9

The splines package

---

**splines-package**  
*Regression Spline Functions and Classes*

**Description**

Regression spline functions and classes.

**Details**

This package provides functions for working with regression splines using the B-spline basis, `bs`, and the natural cubic spline basis, `ns`.

For a complete list of functions, use `library(help = "splines")`.

**Author(s)**

Douglas M. Bates <bates@stat.wisc.edu> and William N. Venables <Bill.Venables@csiro.au>

Maintainer: R Core Team <R-core@r-project.org>

---

**asVector**  
*Coerce an Object to a Vector*

**Description**

This is a generic function. Methods for this function coerce objects of given classes to vectors.

**Usage**

`asVector(object)`

**Arguments**

- `object`  
  An object.
Details

Methods for vector coercion in new classes must be created for the asVector generic instead of as.vector. The as.vector function is internal and not easily extended. Currently the only class with an asVector method is the xyVector class.

Value

a vector

Author(s)

Douglas Bates and Bill Venables

See Also

xyVector

Examples

```r
require(stats)
isp1 <- interpSpline(weight ~ height, women)
pred <- predict(isp1)
class(pred)
utils::str(pred)
asVector(pred)
```

Description

Create a monotone inverse of a monotone natural spline.

Usage

backSpline(object)

Arguments

object an object that inherits from class nbSpline or npolySpline. That is, the object must represent a natural interpolation spline but it can be either in the B-spline representation or the piecewise polynomial one. The spline is checked to see if it represents a monotone function.

Value

An object of class polySpline that contains the piecewise polynomial representation of a function that has the appropriate values and derivatives at the knot positions to be an inverse of the spline represented by object. Technically this object is not a spline because the second derivative is not constrained to be continuous at the knot positions. However, it is often a much better approximation to the inverse than fitting an interpolation spline to the y/x pairs.
Author(s)

Douglas Bates and Bill Venables

See Also

`interpSpline`

Examples

```r
require(graphics)
isl1 <- interpSpline( women$height, women$weight )
bspl1 <- backSpline( isl1 )
plot( bspl1 )  # plots over the range of the knots
points( women$weight, women$height )
```

Description

Generate the B-spline basis matrix for a polynomial spline.

Usage

```r
bs(x, df = NULL, knots = NULL, degree = 3, intercept = FALSE,
  Boundary.knots = range(x))
```

Arguments

- `x` the predictor variable. Missing values are allowed.
- `df` degrees of freedom; one can specify `df` rather than `knots`; `bs()` then chooses `df=degree` (minus one if there is an intercept) knots at suitable quantiles of `x` (which will ignore missing values). The default, `NULL`, corresponds to no inner knots, i.e., `degree = intercept`.
- `knots` the internal breakpoints that define the spline. The default is `NULL`, which results in a basis for ordinary polynomial regression. Typical values are the mean or median for one knot, quantiles for more knots. See also `Boundary.knots`.
- `degree` degree of the piecewise polynomial—default is 3 for cubic splines.
- `intercept` if `TRUE`, an intercept is included in the basis; default is `FALSE`.
- `Boundary.knots` boundary points at which to anchor the B-spline basis (default the range of the data). If both `knots` and `Boundary.knots` are supplied, the basis parameters do not depend on `x`. Data can extend beyond `Boundary.knots`.

Details

`bs` is based on the function `spline.des`. It generates a basis matrix for representing the family of piecewise polynomials with the specified interior knots and degree, evaluated at the values of `x`. A primary use is in modeling formulas to directly specify a piecewise polynomial term in a model.
Value

A matrix of dimension c(length(x), df), where either df was supplied or if knots were supplied, 
\( df = \text{length(knots)} + \text{degree} + 1 \) if there is an intercept. Attributes are returned that 
correspond to the arguments to bs, and explicitly give the knots, Boundary.knots etc for use by 
predict.bs().

References

See Also

ns, poly, smooth.spline, predict.bs, SafePrediction

Examples

```r
require(stats); require(graphics)
bs(women$height, df = 5)
summary(fm1 <- lm(weight ~ bs(height, df = 5), data = women))

## example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, length.out = 200)
lines(ht, predict(fm1, data.frame(height = ht)))
```

interpSpline

Create an Interpolation Spline

Create an interpolation spline, either from x and y vectors, or from a formula/data.frame combination.

Usage

```r
interpSpline(obj1, obj2, bSpline = FALSE, period = NULL, 
na.action = na.fail)
```

Arguments

- **obj1**
  - Either a numeric vector of x values or a formula.
- **obj2**
  - If obj1 is numeric this should be a numeric vector of the same length. If obj1 
is a formula this can be an optional data frame in which to evaluate the names in 
the formula.
- **bSpline**
  - If TRUE the b-spline representation is returned, otherwise the piecewise polynomial representation is returned. Defaults to FALSE.
- **period**
  - An optional positive numeric value giving a period for a periodic interpolation 
spline.
- **na.action**
  - a optional function which indicates what should happen when the data contain 
NAs. The default action (na.omit) is to omit any incomplete observations. The 
alternative action na.fail causes interpSpline to print an error message and 
terminate if there are any incomplete observations.
Value

An object that inherits from class `spline`. The object can be in the B-spline representation, in which case it will be of class `nbspine` for natural B-spline, or in the piecewise polynomial representation, in which case it will be of class `nopolySpline`.

Douglas Bates and Bill Venables

See Also

`splineKnots`, `splineOrder`, `periodicSpline`.

Examples

```r
require(graphics); require(stats)
ispl <- interpSpline( women$height, women$weight )
ispl2 <- interpSpline( weight ~ height, women )
# ispl and ispl2 should be the same
plot( predict( ispl, seq( 55, 75, length.out = 51 ) ), type = "l" )
points( women$height, women$weight )
plot( ispl )  # plots over the range of the knots
points( women$height, women$weight )
splineKnots( ispl )
```

---

ns

### Generate a Basis Matrix for Natural Cubic Splines

**Description**

Generate the B-spline basis matrix for a natural cubic spline.

**Usage**

```r
ns(x, df = NULL, knots = NULL, intercept = FALSE,
    Boundary.knots = range(x))
```

**Arguments**

- `x` the predictor variable. Missing values are allowed.
- `df` degrees of freedom. One can supply `df` rather than `knots`; `ns()` then chooses `df - 1 - intercept` knots at suitably chosen quantiles of `x` (which will ignore missing values). The default, `df = 1`, corresponds to no knots.
- `knots` breakpoints that define the spline. The default is no knots; together with the natural boundary conditions this results in a basis for linear regression on `x`. Typical values are the mean or median for one knot, quantiles for more knots. See also `Boundary.knots`.
- `intercept` if `TRUE`, an intercept is included in the basis; default is `FALSE`.
- `Boundary.knots` boundary points at which to impose the natural boundary conditions and anchor the B-spline basis (default the range of the data). If both knots and `Boundary.knots` are supplied, the basis parameters do not depend on `x`. Data can extend beyond `Boundary.knots`.
Details

ns is based on the function spline.des. It generates a basis matrix for representing the family of piecewise-cubic splines with the specified sequence of interior knots, and the natural boundary conditions. These enforce the constraint that the function is linear beyond the boundary knots, which can either be supplied or default to the extremes of the data.

A primary use is in modeling formula to directly specify a natural spline term in a model: see the examples.

Value

A matrix of dimension length(x) * df where either df was supplied or if knots were supplied, df = length(knots) + 1 + intercept. Attributes are returned that correspond to the arguments to ns, and explicitly give the knots, Boundary.knots etc for use by predict.ns().

ns(women$height, df = 5)
summary(fm1 <- lm(weight ~ ns(height, df = 5), data = women))

## To see what knots were selected
attr(terms(fm1), "predvars")

## example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)"
ht <- seq(57, 73, length.out = 200)
lines(ht, predict(fm1, data.frame(height = ht)))

periodicSpline

Create a Periodic Interpolation Spline

Description

Create a periodic interpolation spline, either from x and y vectors, or from a formula/data.frame combination.

Usage

periodicSpline(obj1, obj2, knots, period = 2*pi, ord = 4)
polySpline

Arguments

- obj1: either a numeric vector of x values or a formula.
- obj2: if obj1 is numeric this should be a numeric vector of the same length. If obj1 is a formula this can be an optional data frame in which to evaluate the names in the formula.
- knots: optional numeric vector of knot positions.
- period: positive numeric value giving the period for the periodic spline. Defaults to \(2 \times \pi\).
- ord: integer giving the order of the spline, at least 2. Defaults to 4. See \texttt{splineOrder} for a definition of the order of a spline.

Value

An object that inherits from class \texttt{spline}. The object can be in the B-spline representation, in which case it will be a \texttt{pbSpline} object, or in the piecewise polynomial representation (a \texttt{ppolySpline} object).

Author(s)

Douglas Bates and Bill Venables

See Also

\texttt{splineKnots, interpSpline}

Examples

```r
require(graphics); require(stats)
x <- seq(-\pi, \pi, length.out = 16)[-1]
y <- sin(x)
frm <- data.frame(x, y)
pispl <- periodicSpline(x, y, period = 2 * \pi)
pispl
pispl2 <- periodicSpline(y ~ x, frm, period = 2 * \pi)
stopifnot(all.equal(pispl, pispl2))  # pispl and pispl2 are the same
plot(pispl)  # displays over one period
points(y ~ x, col = "brown")
plot(predict(pispl, seq(-3*\pi, 3*\pi, length.out = 101)), type = "l")
```

Description

Create the piecewise polynomial representation of a spline object.

Usage

\texttt{polySpline(object, \ldots)}

\texttt{as.polySpline(object, \ldots)}
arguments

object: An object that inherits from class `spline`.

...: Optional additional arguments. At present no additional arguments are used.

Value

An object that inherits from class `polySpline`. This is the piecewise polynomial representation of a univariate spline function. It is defined by a set of distinct numeric values called knots. The spline function is a polynomial function between each successive pair of knots. At each interior knot the polynomial segments on each side are constrained to have the same value of the function and some of its derivatives.

Author(s)

Douglas Bates and Bill Venables

See Also

`interpolateSpline`, `periodicSpline`, `splineKnots`, `splineOrder`

Examples

```r
require(graphics)
ispl <- polySpline(interpSpline( weight ~ height, women, bspline = TRUE))
print(ispl)  # print the piecewise polynomial representation
plot(ispl)   # plots over the range of the knots
points(women$height, women$weight)

predict.bs

Evaluate a Spline Basis

Description

Evaluate a predefined spline basis at given values.

Usage

```r
## S3 method for class 'bs'
predict(object, newx, ...)
```

```r
## S3 method for class 'ns'
predict(object, newx, ...)
```

Arguments

object: the result of a call to `bs` or `ns` having attributes describing knots, degree, etc.

newx: the x values at which evaluations are required.

...: Optional additional arguments. At present no additional arguments are used.
Value

An object just like object, except evaluated at the new values of x.

These are methods for the generic function `predict` for objects inheriting from classes "bs" or "ns". See `predict` for the general behavior of this function.

See Also

bs, ns, poly.

Examples

```r
require(stats)
basis <- ns(women$height, df = 5)
newX <- seq(58, 72, length.out = 51)
# evaluate the basis at the new data
predict(basis, newX)
```

predict.bSpline  

Evaluate a Spline at New Values of x

Description

The predict methods for the classes that inherit from the virtual classes bSpline and polySpline are used to evaluate the spline or its derivatives. The plot method for a spline object first evaluates predict with the x argument missing, then plots the resulting xyVector with type = "l".

Usage

```r
## S3 method for class 'bSpline'
predict(object, x, nseg = 50, deriv = 0, ...)
## S3 method for class 'nbSpline'
predict(object, x, nseg = 50, deriv = 0, ...)
## S3 method for class 'pbSpline'
predict(object, x, nseg = 50, deriv = 0, ...)
## S3 method for class 'npolySpline'
predict(object, x, nseg = 50, deriv = 0, ...)
## S3 method for class 'ppolySpline'
predict(object, x, nseg = 50, deriv = 0, ...)
```

Arguments

- `object` An object that inherits from the bSpline or the polySpline class.
- `x` A numeric vector of x values at which to evaluate the spline. If this argument is missing a suitable set of x values is generated as a sequence of nseg segments spanning the range of the knots.
- `nseg` A positive integer giving the number of segments in a set of equally-spaced x values spanning the range of the knots in object. This value is only used if x is missing.
- `deriv` An integer between 0 and splineOrder(object) - 1 specifying the derivative to evaluate.
- `...` further arguments passed to or from other methods.
splineDesign

Design Matrix for B-splines

Description

Evaluate the design matrix for the B-splines defined by knots at the values in x.

Usage

splineDesign(knots, x, ord = 4, derivs, outer.ok = FALSE, sparse = FALSE)
spline.des (knots, x, ord = 4, derivs, outer.ok = FALSE, sparse = FALSE)
Arguments

knots  
a numeric vector of knot positions with non-decreasing values.

x  
a numeric vector of values at which to evaluate the B-spline functions or derivatives. Unless outer.ok is true, the values in x must be between knots[ord] and knots[ length(knots) + 1 - ord ].

ord  
a positive integer giving the order of the spline function. This is the number of coefficients in each piecewise polynomial segment, thus a cubic spline has order 4. Defaults to 4.

derivs  
an integer vector of the same length as x and with values between 0 and ord - 1. The derivative of the given order is evaluated at the x positions. Defaults to a vector of zeroes of the same length as x.

outer.ok  
logical indicating if x should be allowed outside the inner knots, see the x argument.

sparse  
logical indicating if the result should inherit from class sparseMatrix (package Matrix).

Value

A matrix with length(x) rows and length(knots) - ord columns. The i'th row of the matrix contains the coefficients of the B-splines (or the indicated derivative of the B-splines) defined by the knot vector and evaluated at the i'th value of x. Each B-spline is defined by a set of ord successive knots so the total number of B-splines is length(knots) - ord.

Note

The older spline.des function takes the same arguments but returns a list with several components including knots, ord, derivs, and design. The design component is the same as the value of the splineDesign function.

Author(s)

Douglas Bates and Bill Venables

Examples

```r
require(graphics)
splineDesign(knots = 1:10, x = 4:7)
# visualize band structure
Matrix:::drop0(zapsmall(6*splineDesign(knots = 1:40, x = 4:37, sparse = TRUE)))

knots <- c(1,1.8,3:5,6.5,7,8,1,9.2,10)  # 10 => 10-4 = 6 Basis splines
x <- seq(min(knots)-1, max(knots)+1, length.out = 501)
bb <- splineDesign(knots, x = x, outer.ok = TRUE)

plot(range(x), c(0,1), type = "n", xlab = "x", ylab = "",
     main = "B-splines - sum to 1 inside inner knots")
mtext(expression(B[j](x) *" and "* sum(B[j](x), j == 1, 6)), adj = 0)
abline(v = knots, lty = 3, col = "light gray")
abline(v = knots[c(4,length(knots)-3)], lty = 3, col = "gray10")
lines(x, rowSums(bb), col = "gray", lwd = 2)
matlines(x, bb, ylim = c(0,1), lty = 1)
```
splineKnots  

Knot Vector from a Spline

Description
Return the knot vector corresponding to a spline object.

Usage
splineKnots(object)

Arguments
object an object that inherits from class "spline".

Value
A non-decreasing numeric vector of knot positions.

Author(s)
Douglas Bates and Bill Venables

Examples
isp1 <- interpSpline( weight ~ height, women )
splineKnots( ispl )

splineOrder  

Determine the Order of a Spline

Description
Return the order of a spline object.

Usage
splineOrder(object)

Arguments
object An object that inherits from class "spline".

Details
The order of a spline is the number of coefficients in each piece of the piecewise polynomial representation. Thus a cubic spline has order 4.

Value
A positive integer.
**Author(s)**

Douglas Bates and Bill Venables

**See Also**

`splineKnots, interpSpline, periodicSpline`

**Examples**

```r
splineOrder( interpSpline( weight ~ height, women ) )
```

---

**Description**

Create an object to represent a set of x-y pairs. The resulting object can be treated as a matrix or as a data frame or as a vector. When treated as a vector it reduces to the y component only.

The result of functions such as `predict.spline` is returned as an `xyVector` object so the x-values used to generate the y-positions are retained, say for purposes of generating plots.

**Usage**

```r
xyVector(x, y)
```

**Arguments**

- `x` a numeric vector
- `y` a numeric vector of the same length as `x`

**Value**

An object of class `xyVector` with components

- `x` a numeric vector
- `y` a numeric vector of the same length as `x`

**Author(s)**

Douglas Bates and Bill Venables

**Examples**

```r
require(stats); require(graphics)
ispl <- interpSpline( weight ~ height, women )
weights <- predict( ispl, seq( 55, 75, length.out = 51 ) )
class( weights )
plot( weights, type = "l", xlab = "height", ylab = "weight" )
points( women$height, women$weight )
weights
```
Chapter 10

.checkMFClasses  Functions to Check the Type of Variables passed to Model Frames

Description

.checkMFClasses checks if the variables used in a predict method agree in type with those used for fitting.
.MFclass categorizes variables for this purpose.

Usage

.checkMFClasses(cl, m, ordNotOK = FALSE)
.MFclass(x)
.getXlevels(Terms, m)
Arguments

cl a character vector of class descriptions to match.
m a model frame.
x any R object.
ordNotOK logical: are ordered factors different?
Terms a terms object.

Details

For applications involving model.matrix such as linear models we do not need to differentiate between ordered factors and factors as although these affect the coding, the coding used in the fit is already recorded and imposed during prediction. However, other applications may treat ordered factors differently: \texttt{rpart} does, for example.

Value

\texttt{class} returns a character string, one of "logical", "ordered", "factor", "numeric", "nmatrix.*" (a numeric matrix with a number of columns appended) or "other".

\texttt{getXlevels} returns a named character vector, or \texttt{NULL}.

\---

\textbf{acf}  \hspace{2cm} \textit{Auto- and Cross- Covariance and -Correlation Function Estimation}

\---

Description

The function \texttt{acf} computes (and by default plots) estimates of the autocovariance or autocorrelation function. Function \texttt{pacf} is the function used for the partial autocorrelations. Function \texttt{ccf} computes the cross-correlation or cross-covariance of two univariate series.

Usage

\begin{verbatim}
acf(x, lag.max = NULL,
    type = c("correlation", "covariance", "partial"),
    plot = TRUE, na.action = na.fail, demean = TRUE, ...)

pacf(x, lag.max, plot, na.action, ...)

## Default S3 method:
pacf(x, lag.max = NULL, plot = TRUE, na.action = na.fail,
    ...)  

ccf(x, y, lag.max = NULL, type = c("correlation", "covariance"),
    plot = TRUE, na.action = na.fail, ...)

## S3 method for class 'acf'
x[i, j]
\end{verbatim}
**acf**

Arguments

- **x, y**
  - a univariate or multivariate (not ccf) numeric time series object or a numeric vector or matrix, or an "acf" object.
- **lag.max**
  - maximum lag at which to calculate the acf. Default is $10 \log_{10}(N/m)$ where $N$ is the number of observations and $m$ the number of series. Will be automatically limited to one less than the number of observations in the series.
- **type**
  - character string giving the type of acf to be computed. Allowed values are "correlation" (the default), "covariance" or "partial".
- **plot**
  - logical. If TRUE (the default) the acf is plotted.
- **na.action**
  - function to be called to handle missing values. na.pass can be used.
- **demean**
  - logical. Should the covariances be about the sample means?
- **...**
  - further arguments to be passed to plot.acf.
- **i**
  - a set of lags (time differences) to retain.
- **j**
  - a set of series (names or numbers) to retain.

Details

For type = "correlation" and "covariance", the estimates are based on the sample covariance. (The lag 0 autocorrelation is fixed at 1 by convention.)

By default, no missing values are allowed. If the na.action function passes through missing values (as na.pass does), the covariances are computed from the complete cases. This means that the estimate computed may well not be a valid autocorrelation sequence, and may contain missing values. Missing values are not allowed when computing the PACF of a multivariate time series.

The partial correlation coefficient is estimated by fitting autoregressive models of successively higher orders up to lag.max.

The generic function plot has a method for objects of class "acf".

The lag is returned and plotted in units of time, and not numbers of observations.

There are print and subsetting methods for objects of class "acf".

Value

An object of class "acf", which is a list with the following elements:

- **lag**
  - A three dimensional array containing the lags at which the acf is estimated.
- **acf**
  - An array with the same dimensions as lag containing the estimated acf.
- **type**
  - The type of correlation (same as the type argument).
- **n.used**
  - The number of observations in the time series.
- **series**
  - The name of the series x.
- **snames**
  - The series names for a multivariate time series.

The lag k value returned by ccf(x, y) estimates the correlation between x[t+k] and y[t]. The result is returned invisibly if plot is TRUE.

Author(s)

acf2AR

Compute an AR Process Exactly Fitting an ACF

Description

Compute an AR process exactly fitting an autocorrelation function.

Usage

acf2AR(acf)

Arguments

acf An autocorrelation or autocovariance sequence.

Value

A matrix, with one row for the computed AR(p) coefficients for 1 <= p <= length(acf).

See Also

ARMAacf, ar.yw which does this from an empirical ACF.
Examples

```r
(Acf <- ARMAacf(c(0.6, 0.3, -0.2)))
acf2ar(Acf)
```

**Description**

Compute all the single terms in the scope argument that can be added to or dropped from the model, fit those models and compute a table of the changes in fit.

**Usage**

```r
add1(object, scope, ...)  
# Default S3 method:
add1(object, scope, scale = 0, test = c("none", "Chisq"),
    k = 2, trace = FALSE, ...)

# S3 method for class 'lm'
add1(object, scope, scale = 0, test = c("none", "Chisq", "F"),
    x = NULL, k = 2, ...)

# S3 method for class 'glm'
add1(object, scope, scale = 0,
    test = c("none", "Rao", "LRT", "Chisq", "F"),
    x = NULL, k = 2, ...)

drop1(object, scope, ...)
# Default S3 method:
drop1(object, scope, scale = 0, test = c("none", "Chisq"),
    k = 2, trace = FALSE, ...)

# S3 method for class 'lm'
drop1(object, scope, scale = 0, all.cols = TRUE,
    test = c("none", "Chisq", "F"), k = 2, ...)

# S3 method for class 'glm'
drop1(object, scope, scale = 0,
    test = c("none", "Rao", "LRT", "Chisq", "F"),
    k = 2, ...)
```

**Arguments**

- **object**: a fitted model object.
- **scope**: a formula giving the terms to be considered for adding or dropping.
- **scale**: an estimate of the residual mean square to be used in computing $C_p$. Ignored if 0 or NULL.
should the results include a test statistic relative to the original model? The F test
is only appropriate for \texttt{lm} and \texttt{aov} models or perhaps for \texttt{glm} fits with estimated
dispersion. The \(\chi^2\) test can be an exact test (\texttt{lm} models with known scale) or a
likelihood-ratio test or a test of the reduction in scaled deviance depending on the
method. For \texttt{glm} fits, you can also choose "LRT" and "Rao" for likelihood ratio
tests and Rao’s efficient score test. The former is synonymous with "Chisq"
(although both have an asymptotic chi-square distribution).

\texttt{k} \quad the penalty constant in AIC / \(C_p\).

\texttt{trace} \quad if \texttt{TRUE}, print out progress reports.

\texttt{x} \quad a model matrix containing columns for the fitted model and all terms in the upper
scope. Useful if \texttt{add1} is to be called repeatedly. \textbf{Warning:} no checks are done
on its validity.

\texttt{all.cols} \quad (Provided for compatibility with \texttt{S.}) Logical to specify whether all columns of
the design matrix should be used. If \texttt{FALSE} then non-estimable columns are
dropped, but the result is not usually statistically meaningful.

\ldots \quad further arguments passed to or from other methods.

**Details**

For \texttt{drop1} methods, a missing \texttt{scope} is taken to be all terms in the model. The hierarchy is respected
when considering terms to be added or dropped: all main effects contained in a second-order inter-
action must remain, and so on.

In a \texttt{scope} formula \(\cdot\) means ‘what is already there’.

The methods for \texttt{lm} and \texttt{glm} are more efficient in that they do not recompute the model matrix and
call the \texttt{fit} methods directly.

The default output table gives AIC, defined as minus twice log likelihood plus \(2p\) where \(p\) is the rank
of the model (the number of effective parameters). This is only defined up to an additive constant
(like log-likelihoods). For linear Gaussian models with fixed scale, the constant is chosen to give
Mallows’ \(C_p\), \(\text{RSS}/\text{scale} + 2p - n\). Where \(C_p\) is used, the column is labelled as \(C_p\) rather than
AIC.

The F tests for the "\texttt{glm}" methods are based on analysis of deviance tests, so if the dispersion is
estimated it is based on the residual deviance, unlike the F tests of \texttt{anova.glm}.

**Value**

An object of class "anova" summarizing the differences in fit between the models.

**Warning**

The model fitting must apply the models to the same dataset. Most methods will attempt to use a
subset of the data with no missing values for any of the variables if \texttt{na.action = na.omit}, but this
may give biased results. Only use these functions with data containing missing values with great care.

The default methods make calls to the function \texttt{nobs} to check that the number of observations
involved in the fitting process remained unchanged.
Note

These are not fully equivalent to the functions in S. There is no keep argument, and the methods used are not quite so computationally efficient.

Their authors’ definitions of Mallows’ $C_p$ and Akaike’s AIC are used, not those of the authors of the models chapter of S.

Author(s)

The design was inspired by the S functions of the same names described in Chambers (1992).

add1(glm.093, scope = ~outcome*treatment, test = "Rao")  # Pearson Chi-square
```

addmargins

*Puts Arbitrary Margins on Multidimensional Tables or Arrays*

Description

For a given table one can specify which of the classifying factors to expand by one or more levels to hold margins to be calculated. One may for example form sums and means over the first dimension and medians over the second. The resulting table will then have two extra levels for the first dimension and one extra level for the second. The default is to sum over all margins in the table. Other possibilities may give results that depend on the order in which the margins are computed. This is flagged in the printed output from the function.

Usage

```r
addmargins(A, margin = seq_along(dim(A)), FUN = sum, quiet = FALSE)
```
Arguments

A: table or array. The function uses the presence of the "dim" and "dimnames" attributes of A.

margin: vector of dimensions over which to form margins. Margins are formed in the order in which dimensions are specified in margin.

FUN: list of the same length as margin, each element of the list being either a function or a list of functions. Names of the list elements will appear as levels in dimnames of the result. Unnamed list elements will have names constructed: the name of a function or a constructed name based on the position in the table.

quiet: logical which suppresses the message telling the order in which the margins were computed.

Details

If the functions used to form margins are not commutative the result depends on the order in which margins are computed. Annotation of margins is done via naming the FUN list.

Value

A table or array with the same number of dimensions as A, but with extra levels of the dimensions mentioned in margin. The number of levels added to each dimension is the length of the entries in FUN. A message with the order of computation of margins is printed.

aggregate

aggregate(x, ..., by =)

Arguments

x

an R object.

by

a list of grouping elements, each as long as the variables in the data frame x. The elements are coerced to factors before use.

FUN

a function to compute the summary statistics which can be applied to all data subsets.

simplify

a logical indicating whether results should be simplified to a vector or matrix if possible.

Description

Splits the data into subsets, computes summary statistics for each, and returns the result in a convenient form.

Usage

aggregate(x, ..., by =)

Arguments

x

an R object.

by

a list of grouping elements, each as long as the variables in the data frame x. The elements are coerced to factors before use.

FUN

a function to compute the summary statistics which can be applied to all data subsets.

simplify

a logical indicating whether results should be simplified to a vector or matrix if possible.
aggregate

**formula**
a formula, such as \( y \sim x \) or \( \text{cbind}(y1, y2) \sim x1 + x2 \), where the \( y \) variables are numeric data to be split into groups according to the grouping \( x \) variables (usually factors).

**data**
a data frame (or list) from which the variables in formula should be taken.

**subset**
an optional vector specifying a subset of observations to be used.

**na.action**
a function which indicates what should happen when the data contain NA values. The default is to ignore missing values in the given variables.

**nfrequency**
new number of observations per unit of time; must be a divisor of the frequency of \( x \).

**ndeltat**
new fraction of the sampling period between successive observations; must be a divisor of the sampling interval of \( x \).

**ts.eps**
tolerance used to decide if \( nfrequency \) is a sub-multiple of the original frequency.

... further arguments passed to or used by methods.

**Details**

aggregate is a generic function with methods for data frames and time series.

The default method, aggregate.default, uses the time series method if \( x \) is a time series, and otherwise coerces \( x \) to a data frame and calls the data frame method.

aggregate.data.frame is the data frame method. If \( x \) is not a data frame, it is coerced to one, which must have a non-zero number of rows. Then, each of the variables (columns) in \( x \) is split into subsets of cases (rows) of identical combinations of the components of by, and \( \text{FUN} \) is applied to each such subset with further arguments in ... passed to it. The result is reformatted into a data frame containing the variables in by and \( x \). The ones arising from by contain the unique combinations of grouping values used for determining the subsets, and the ones arising from \( x \) the corresponding summaries for the subset of the respective variables in \( x \). If \( \text{simplify} \) is true, summaries are simplified to vectors or matrices if they have a common length of one or greater than one, respectively; otherwise, lists of summary results according to subsets are obtained. Rows with missing values in any of the by variables will be omitted from the result. (Note that versions of R prior to 2.11.0 required \( \text{FUN} \) to be a scalar function.)

aggregate.formula is a standard formula interface to aggregate.data.frame.

aggregate.ts is the time series method, and requires \( \text{FUN} \) to be a scalar function. If \( x \) is not a time series, it is coerced to one. Then, the variables in \( x \) are split into appropriate blocks of length \( \text{frequency}(x) / nfrequency \), and \( \text{FUN} \) is applied to each such block, with further (named) arguments in ... passed to it. The result returned is a time series with frequency \( nfrequency \) holding the aggregated values. Note that this make most sense for a quarterly or yearly result when the original series covers a whole number of quarters or years: in particular aggregating a monthly series to quarters starting in February does not give a conventional quarterly series.

\( \text{FUN} \) is passed to match.fun, and hence it can be a function or a symbol or character string naming a function.

**Value**

For the time series method, a time series of class "ts" or class c("mts", "ts").

For the data frame method, a data frame with columns corresponding to the grouping variables in by followed by aggregated columns from \( x \). If the by has names, the non-empty times are used to label the columns in the results, with unnamed grouping variables being named Group.i for by[[i]].

**Examples**
```r
```## Compute the averages for the variables in 'state.x77', grouped
## according to the region (Northeast, South, North Central, West) that  
## each state belongs to.
aggregate(state.x77, list(Region = state.region), mean)

## Compute the averages according to region and the occurrence of more  
## than 130 days of frost.
aggregate(state.x77,  
  list(Region = state.region,  
       Cold = state.x77[, "Frost"] > 130),  
       mean)  
## (Note that no state in 'South' is THAT cold.)

## Example with character variables and NAs
testDF <- data.frame(v1 = c(1,3,5,7,8,3,5,NA,4,5,7,9),  
                      v2 = c(11,33,55,77,88,33,55,NA,44,55,77,99))
by1 <- c("red", "blue", 1, 2, NA, "big", 1, 2, "red", 1, NA, 12)
by2 <- c("wet", "dry", 99, 95, NA, "damp", 95, 99, "red", 99, NA, NA)
aggregate(x = testDF, by = list(by1, by2), FUN = "mean")

# and if you want to treat NAs as a group
fby1 <- factor(by1, exclude = "")
fby2 <- factor(by2, exclude = "")
aggregate(x = testDF, by = list(fby1, fby2), FUN = "mean")

## Formulas, one ~ one, one ~ many, many ~ one, and many ~ many:
aggregate(weight ~ feed, data = chickwts, mean)
aggregate(breaks ~ wool + tension, data = warpbreaks, mean)
aggregate(cbind(Ozone, Temp) ~ Month, data = airquality, mean)
aggregate(cbind(ncases, ncontrols) ~ alcgp + tobgp, data = esoph, sum)

## Dot notation:
aggregate(. ~ Species, data = iris, mean)
aggregate(len ~ ., data = ToothGrowth, mean)

## Often followed by xtabs():
ag <- aggregate(len ~ ., data = ToothGrowth, mean)
xtabs(len ~ ., data = ag)```
### AIC

**Aic**

**Akaike’s An Information Criterion**

**Description**

Generic function calculating Akaike’s ‘An Information Criterion’ for one or several fitted model objects for which a log-likelihood value can be obtained, according to the formula \(-2\log\text{-likelihood} + kn_{\text{par}}\), where \(n_{\text{par}}\) represents the number of parameters in the fitted model, and \(k = 2\) for the usual AIC, or \(k = \log(n)\) (\(n\) being the number of observations) for the so-called BIC or SBC (Schwarz’s Bayesian criterion).

**Usage**

AIC(object, ..., k = 2)

BIC(object, ...)

**Arguments**

- **object**
  - a fitted model object for which there exists a `logLik` method to extract the corresponding log-likelihood, or an object inheriting from class `logLik`.
- **...**
  - optionally more fitted model objects.
- **k**
  - numeric, the penalty per parameter to be used; the default \(k = 2\) is the classical AIC.

**Details**

When comparing models fitted by maximum likelihood to the same data, the smaller the AIC or BIC, the better the fit. The theory of AIC requires that the log-likelihood has been maximized: whereas AIC can be computed for models not fitted by maximum likelihood, their AIC values should not be compared.

Examples of models not ‘fitted to the same data’ are where the response is transformed (accelerated-life models are fitted to log-times) and where contingency tables have been used to summarize data. These are generic functions (with S4 generics defined in package stats4): however methods should be defined for the log-likelihood function `logLik` rather than these functions: the action of their default methods is to call `logLik` on all the supplied objects and assemble the results. Note that in several common cases `logLik` does not return the value at the MLE: see its help page.

The log-likelihood and hence the AIC/BIC is only defined up to an additive constant. Different constants have conventionally been used for different purposes and so `extractAIC` and AIC may give different values (and do for models of class "lm": see the help for `extractAIC`). Particular care is needed when comparing fits of different classes (with, for example, a comparison of a Poisson and gamma GLM being meaningless since one has a discrete response, the other continuous). BIC is defined as `AIC(object, ..., k = \log(\text{nobs(object)})`). This needs the number of observations to be known: the default method looks first for a "nobs" attribute on the return value from the `logLik` method, then tries the `nobs` generic, and if neither succeed returns BIC as NA.
Value

If just one object is provided, a numeric value with the corresponding AIC (or BIC, or ..., depending on \( k \)).

If multiple objects are provided, a data.frame with rows corresponding to the objects and columns representing the number of parameters in the model (df) and the AIC or BIC.

Author(s)

Originally by José Pinheiro and Douglas Bates, more recent revisions by R-core.

Examples

```r
lm1 <- lm(Fertility ~ ., data = swiss)
AIC(lm1)
stopifnot(all.equal(AIC(lm1),
                  AIC(logLik(lm1))))
BIC(lm1)

lm2 <- update(lm1, . ~ . - Examination)
AIC(lm1, lm2)
BIC(lm1, lm2)
```

---

**alias**  

Find Aliases (Dependencies) in a Model

Description

Find aliases (linearly dependent terms) in a linear model specified by a formula.

Usage

```r
aliases(object, ...)
```

```
## S3 method for class 'formula'
aliases(object, data, ...)
```

```
## S3 method for class 'lm'
alises(object, complete = TRUE, partial = FALSE, partial.pattern = FALSE, ...)
```
Arguments

object  A fitted model object, for example from `lm` or `aov`, or a formula for `alias.formula`.
data   Optionally, a data frame to search for the objects in the formula.
complete Should information on complete aliasing be included?
partial Should information on partial aliasing be included?
partial.pattern Should partial aliasing be presented in a schematic way? If this is done, the results are presented in a more compact way, usually giving the deciles of the coefficients.

... further arguments passed to or from other methods.

Details

Although the main method is for class "lm", `alias` is most useful for experimental designs and so is used with fits from `aov`. Complete aliasing refers to effects in linear models that cannot be estimated independently of the terms which occur earlier in the model and so have their coefficients omitted from the fit. Partial aliasing refers to effects that can be estimated less precisely because of correlations induced by the design.

Some parts of the “lm” method require recommended package `MASS` to be installed.

Value

A list (of class "listof") containing components

- Model  Description of the model; usually the formula.
- Complete  A matrix with columns corresponding to effects that are linearly dependent on the rows.
- Partial  The correlations of the estimable effects, with a zero diagonal. An object of class "mtable" which has its own `print` method.

Note

The aliasing pattern may depend on the contrasts in use: Helmert contrasts are probably most useful. The defaults are different from those in S.

Author(s)

The design was inspired by the S function of the same name described in Chambers et al (1992).

References

Examples

```r
op <- options(contrasts = c("contr.helmert", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
alias(npk.aov)
options(op) # reset
```
anova  

Anova Tables

Description
Compute analysis of variance (or deviance) tables for one or more fitted model objects.

Usage
anova(object, ...)

Arguments
object an object containing the results returned by a model fitting function (e.g., lm or glm).
... additional objects of the same type.

Value
This (generic) function returns an object of class anova. These objects represent analysis-of-variance and analysis-of-deviance tables. When given a single argument it produces a table which tests whether the model terms are significant.
When given a sequence of objects, anova tests the models against one another in the order specified.
The print method for anova objects prints tables in a 'pretty' form.

Warning
The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R’s default of na.action = na.omit is used.

References

See Also
coefficients, effects, fitted.values, residuals, summary, drop1, add1.

---

anova.glm  

Analysis of Deviance for Generalized Linear Model Fits

Description
Compute an analysis of deviance table for one or more generalized linear model fits.

Usage
## S3 method for class 'glm'
anova(object, ..., dispersion = NULL, test = NULL)
**Arguments**

- `object, ...` objects of class `glm`, typically the result of a call to `glm`, or a list of objects for the "glmlist" method.
- `dispersion` the dispersion parameter for the fitting family. By default it is obtained from the object(s).
- `test` a character string, (partially) matching one of "Chisq", "LRT", "Rao", "F" or "Cp". See `stat.anova`.

**Details**

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the residual deviance as each term of the formula is added in turn are given in as the rows of a table, plus the residual deviances themselves.

If more than one object is specified, the table has a row for the residual degrees of freedom and deviance for each model. For all but the first model, the change in degrees of freedom and deviance is also given. (This only makes statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in deviance for the row to the residuals. For models with known dispersion (e.g., binomial and Poisson fits) the chi-squared test is most appropriate, and for those with dispersion estimated by moments (e.g., gaussian, quasibinomial and quasipoisson fits) the F test is most appropriate. Mallows’ $C_p$ statistic is the residual deviance plus twice the estimate of $\sigma^2$ times the residual degrees of freedom, which is closely related to AIC (and a multiple of it if the dispersion is known). You can also choose "LRT" and "Rao" for likelihood ratio tests and Rao’s efficient score test. The former is synonymous with "Chisq" (although both have an asymptotic chi-square distribution).

The dispersion estimate will be taken from the largest model, using the value returned by `summary.glm`. As this will in most cases use a Chisquared-based estimate, the F tests are not based on the residual deviance in the analysis of deviance table shown.

**Value**

An object of class "anova" inheriting from class "data.frame".

**Warning**

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R’s default of `na.action = na.omit` is used, and anova will detect this with an error.

**References**

**See Also**

- `glm`, `anova`.
- `drop1` for so-called ‘type II’ anova where each term is dropped one at a time respecting their hierarchy.
Examples

```r
## --- Continuing the Example from '?glm':

anova(glm.D93)
anova(glm.D93, test = "Cp")
anova(glm.D93, test = "Chisq")
glm.D93a <-
  update(glm.D93, ~treatment*outcome) # equivalent to Pearson Chi-square
anova(glm.D93, glm.D93a, test = "Rao")
```

### anova.lm

**ANOVA for Linear Model Fits**

**Description**

Compute an analysis of variance table for one or more linear model fits.

**Usage**

```r
## S3 method for class 'lm'
anova(object, ...)

## S3 method for class 'lmlist'
anova(object, ..., scale = 0, test = "F")
```

**Arguments**

- `object, ...` objects of class `lm`, usually, a result of a call to `lm`.
- `test` a character string specifying the test statistic to be used. Can be one of "F", "Chisq" or "Cp", with partial matching allowed, or NULL for no test.
- `scale` numeric. An estimate of the noise variance $\sigma^2$. If zero this will be estimated from the largest model considered.

**Details**

Specifying a single object gives a sequential analysis of variance table for that fit. That is, the reductions in the residual sum of squares as each term of the formula is added in turn are given in as the rows of a table, plus the residual sum of squares.

The table will contain F statistics (and P values) comparing the mean square for the row to the residual mean square.

If more than one object is specified, the table has a row for the residual degrees of freedom and sum of squares for each model. For all but the first model, the change in degrees of freedom and sum of squares is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

Optionally the table can include test statistics. Normally the F statistic is most appropriate, which compares the mean square for a row to the residual sum of squares for the largest model considered. If `scale` is specified chi-squared tests can be used. Mallows’ $C_p$ statistic is the residual sum of squares plus twice the estimate of $\sigma^2$ times the residual degrees of freedom.
Value
An object of class "anova" inheriting from class "data.frame".

Warning
The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R’s default of na.action = na.omit is used, and anova.lmlist will detect this with an error.

### same effect via separate models
fit0 <- lm(sr ~ 1, data = LifeCycleSavings)
fit1 <- update(fit0, . ~ . + pop15)
fit2 <- update(fit1, . ~ . + pop75)
fit3 <- update(fit2, . ~ . + dpi)
fit4 <- update(fit3, . ~ . + dddpi)
anova(fit0, fit1, fit2, fit3, fit4, test = "F")
anova(fit4, fit2, fit1, test = "F") # unconventional order
Arguments

object
...
test
Sigma
T
M
X
idata
tol

Arguments

- **object**: an object of class "mlm".
- **...**: further objects of class "mlm".
- **test**: choice of test statistic (see below).
- **Sigma**: (only relevant if test == "Spherical"). Covariance matrix assumed proportional to Sigma.
- **T**: transformation matrix. By default computed from M and X.
- **M**: formula or matrix describing the outer projection (see below).
- **X**: formula or matrix describing the inner projection (see below).
- **idata**: data frame describing intra-block design.
- **tol**: tolerance to be used in deciding if the residuals are rank-deficient: see qr.

Details

The anova.mlm method uses either a multivariate test statistic for the summary table, or a test based on sphericity assumptions (i.e. that the covariance is proportional to a given matrix).

For the multivariate test, Wilks’ statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987). See summary.manova for further details.

For the "Spherical" test, proportionality is usually with the identity matrix but a different matrix can be specified using Sigma. Corrections for asphericity known as the Greenhouse–Geisser, respectively Huynh–Feldt, epsilons are given and adjusted F tests are performed.

It is common to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A transformation matrix T can be given directly or specified as the difference between two projections onto the spaces spanned by M and X, which in turn can be given as matrices or as model formulas with respect to idata (the tests will be invariant to parametrization of the quotient space M/X).

As with anova.lm, all test statistics use the SSD matrix from the largest model considered as the (generalized) denominator.

Contrary to other anova methods, the intercept is not excluded from the display in the single-model case. When contrast transformations are involved, it often makes good sense to test for a zero intercept.

Value

An object of class "anova" inheriting from class "data.frame"

Note

The Huynh–Feldt epsilon differs from that calculated by SAS (as of v. 8.2) except when the DF is equal to the number of observations minus one. This is believed to be a bug in SAS, not in R.

### ansari.test

#### Ansari-Bradley Test

Description

Performs the Ansari-Bradley two-sample test for a difference in scale parameters.

Usage

```r
ansari.test(x, ...)
```

## Default S3 method:
ansari.test(x, y,
            alternative = c("two.sided", "less", "greater"),
            exact = NULL, conf.int = FALSE, conf.level = 0.95,
```
...)

## S3 method for class 'formula'
ansari.test(formula, data, subset, na.action, ...)

### Arguments

- **x**: numeric vector of data values.
- **y**: numeric vector of data values.
- **alternative**: indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
- **exact**: a logical indicating whether an exact p-value should be computed.
- **conf.int**: a logical, indicating whether a confidence interval should be computed.
- **conf.level**: confidence level of the interval.
- **formula**: a formula of the form `lhs ~ rhs` where `lhs` is a numeric variable giving the data values and `rhs` a factor with two levels giving the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- **...**: further arguments to be passed to or from methods.

### Details

Suppose that `x` and `y` are independent samples from distributions with densities \( f((t - m)/s)/s \) and \( f(t - m) \), respectively, where \( m \) is an unknown nuisance parameter and \( s \), the ratio of scales, is the parameter of interest. The Ansari-Bradley test is used for testing the null that \( s = 1 \), the two-sided alternative being that \( s \neq 1 \) (the distributions differ only in variance), and the one-sided alternatives being \( s > 1 \) (the distribution underlying `x` has a larger variance, "greater") or \( s < 1 \) ("less").

By default (if `exact` is not specified), an exact p-value is computed if both samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

Optionally, a nonparametric confidence interval and an estimator for \( s \) are computed. If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations.

Note that mid-ranks are used in the case of ties rather than average scores as employed in Hollander & Wolfe (1973). See, e.g., Hajek, Sidak and Sen (1999), pages 131ff, for more information.

### Value

A list with class "htest" containing the following components:

- **statistic**: the value of the Ansari-Bradley test statistic.
- **p.value**: the p-value of the test.
- **null.value**: the ratio of scales \( s \) under the null, 1.
- **alternative**: a character string describing the alternative hypothesis.
method  the string "Ansari-Bradley test".
data.name  a character string giving the names of the data.
conf.int  a confidence interval for the scale parameter. (Only present if argument conf.int = TRUE.)
estimate  an estimate of the ratio of scales. (Only present if argument conf.int = TRUE.)

Note
To compare results of the Ansari-Bradley test to those of the F test to compare two variances (under the assumption of normality), observe that $s$ is the ratio of scales and hence $s^2$ is the ratio of variances (provided they exist), whereas for the F test the ratio of variances itself is the parameter of interest. In particular, confidence intervals are for $s$ in the Ansari-Bradley test but for $s^2$ in the F test.

## Serum iron determination using Hyland control sera
ramsay <- c(111, 107, 100, 99, 102, 106, 109, 108, 104, 99,
101, 96, 97, 102, 107, 113, 116, 113, 110, 98)
jugn.parekh <- c(107, 108, 106, 98, 105, 103, 110, 105, 104,
ansari.test(ramsay, jugn.parekh)

ansari.test(rnorm(10), rnorm(10, 0, 2), conf.int = TRUE)

## try more points - failed in 2.4.1
ansari.test(rnorm(100), rnorm(100, 0, 2), conf.int = TRUE)
```
Fit an Analysis of Variance Model

Description

Fit an analysis of variance model by a call to `lm` for each stratum.

Usage

```r
aov(formula, data = NULL, projections = FALSE, qr = TRUE,
    contrasts = NULL, ...)
```

Arguments

- `formula`: A formula specifying the model.
- `data`: A data frame in which the variables specified in the formula will be found. If missing, the variables are searched for in the standard way.
- `projections`: Logical flag: should the projections be returned?
- `qr`: Logical flag: should the QR decomposition be returned?
- `contrasts`: A list of contrasts to be used for some of the factors in the formula. These are not used for any `Error` term, and supplying contrasts for factors only in the `Error` term will give a warning.
- `...`: Arguments to be passed to `lm`, such as `subset` or `na.action`. See ‘Details’ about weights.

Details

This provides a wrapper to `lm` for fitting linear models to balanced or unbalanced experimental designs.

The main difference from `lm` is in the way `print`, `summary` and so on handle the fit: this is expressed in the traditional language of the analysis of variance rather than that of linear models.

If the formula contains a single `Error` term, this is used to specify error strata, and appropriate models are fitted within each error stratum.

The formula can specify multiple responses.

Weights can be specified by a `weights` argument, but should not be used with an `Error` term, and are incompletely supported (e.g., not by `model.tables`).

Value

An object of class `c("aov", "lm")` or for multiple responses of class `c("maov", "aov", "m1m", "lm")` or for multiple error strata of class `c("aovlist", "listof")`. There are `print` and `summary` methods available for these.
Note

`aov` is designed for balanced designs, and the results can be hard to interpret without balance: beware that missing values in the response(s) will likely lose the balance. If there are two or more error strata, the methods used are statistically inefficient without balance, and it may be better to use `lme` in package `nlme`.

Balance can be checked with the `replications` function.

The default ‘contrasts’ in R are not orthogonal contrasts, and `aov` and its helper functions will work better with such contrasts: see the examples for how to select these.

Author(s)

The design was inspired by the S function of the same name described in Chambers et al (1992).

Examples

```r

## Set orthogonal contrasts.
op <- options(contrasts = c("contr.helmert", "contr.poly"))
( npk.aov <- aov(yield ~ block + N*P*K, npk) )
summary(npk.aov)
coefficients(npk.aov)

## to show the effects of re-ordering terms contrast the two fits
aov(yield ~ block + N * P + K, npk)
aov(terms(yield ~ block + N * P + K, keep.order = TRUE), npk)

## as a test, not particularly sensible statistically
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
npk.aovE
summary(npk.aovE)
options(op) # reset to previous
```

Description

Return a list of points which linearly interpolate given data points, or a function performing the linear (or constant) interpolation.
Usage

approx (x, y = NULL, xout, method = "linear", n = 50,
yleft, yright, rule = 1, f = 0, ties = mean)

approxfun(x, y = NULL, method = "linear",
yleft, yright, rule = 1, f = 0, ties = mean)

Arguments

x, y numeric vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see xy.coords.
xout an optional set of numeric values specifying where interpolation is to take place.
method specifies the interpolation method to be used. Choices are "linear" or "constant".
n If xout is not specified, interpolation takes place at n equally spaced points spanning the interval \([\min(x), \max(x)]\).
yleft the value to be returned when input x values are less than \(\min(x)\). The default is defined by the value of rule given below.
yright the value to be returned when input x values are greater than \(\max(x)\). The default is defined by the value of rule given below.
rule an integer (of length 1 or 2) describing how interpolation is to take place outside the interval \([\min(x), \max(x)]\). If rule is 1 then NAs are returned for such points and if it is 2, the value at the closest data extreme is used. Use, e.g., rule = 2:1, if the left and right side extrapolation should differ.
f for method = "constant" a number between 0 and 1 inclusive, indicating a compromise between left- and right-continuous step functions. If \(y0\) and \(y1\) are the values to the left and right of the point then the value is \(y0\) if \(f = 0\), \(y1\) if \(f = 1\), and \(y0*(1-f)+y1*f\) for intermediate values. In this way the result is right-continuous for \(f = 0\) and left-continuous for \(f = 1\), even for non-finite \(y\) values.
ties Handling of tied x values. Either a function with a single vector argument returning a single number result or the string "ordered".

Details

The inputs can contain missing values which are deleted, so at least two complete \((x, y)\) pairs are required (for method = "linear", one otherwise). If there are duplicated (tied) x values and ties is a function it is applied to the y values for each distinct x value. Useful functions in this context include mean, min, and max. If ties = "ordered" the x values are assumed to be already ordered. The first y value will be used for interpolation to the left and the last one for interpolation to the right.

Value

approx returns a list with components x and y, containing n coordinates which interpolate the given data points according to the method (and rule) desired.
The function approxfun returns a function performing (linear or constant) interpolation of the given data points. For a given set of x values, this function will return the corresponding interpolated values. It uses data stored in its environment when it was created, the details of which are subject to change.
Warning

The value returned by \texttt{approxfun} contains references to the code in the current version of \texttt{R}; it is not intended to be saved and loaded into a different \texttt{R} session. This is safer for \texttt{R} $\geq$ 3.0.0.

References

See Also

\texttt{spline} and \texttt{splinefun} for spline interpolation.

Examples

```r
require(graphics)

x <- 1:10
y <- rnorm(10)
par(mfrow = c(2,1))
plot(x, y, main = "approx(.) and approxfun(.)")
points(approx(x, y), col = 2, pch = "*")
points(approx(x, y, method = "constant"), col = 4, pch = "*")

f <- approxfun(x, y)
curve(f(x), 0, 11, col = "green")
points(x, y)
is.function(fc <- approxfun(x, y, method = "const")) # TRUE
curve(fc(x), 0, 10, col = "darkblue", add = TRUE)
## different extrapolation on left and right side:
plot(approxfun(x, y, rule = 2:1), 0, 11,
     col = "tomato", add = TRUE, lty = 3, lwd = 2)
## Show treatment of 'ties' :

x <- c(2,2:4,4,4,5,5,7,7)
y <- c(1:6, 5:4, 3:1)
approx(x, y, xout = x)$y # warning
(ay <- approx(x, y, xout = x, ties = "ordered")$y)
stopifnot(ay == c(2,2,3,6,6,6,4,4,1,1,1,1))
approx(x, y, xout = x, ties = min)$y
approx(x, y, xout = x, ties = max)$y
```

\textit{ar} \hspace{1cm} \textbf{Fit Autoregressive Models to Time Series}

Description

Fit an autoregressive time series model to the data, by default selecting the complexity by AIC.
Usage

```r
ar(x, aic = TRUE, order.max = NULL,
   method = c("yule-walker", "burg", "ols", "mle", "yw"),
   na.action, series, ...)
```

```r
ar.burg(x, ...)
## Default S3 method:
ar.burg(x, aic = TRUE, order.max = NULL,
       na.action = na.fail, demean = TRUE, series,
       var.method = 1, ...)
## S3 method for class 'mts'
ar.burg(x, aic = TRUE, order.max = NULL,
       na.action = na.fail, demean = TRUE, series,
       var.method = 1, ...)
```

```r
ar.yw(x, ...)
## Default S3 method:
ar.yw(x, aic = TRUE, order.max = NULL,
      na.action = na.fail, demean = TRUE, series, ...)
## S3 method for class 'mts'
ar.yw(x, aic = TRUE, order.max = NULL,
      na.action = na.fail, demean = TRUE, series,
      var.method = 1, ...)
```

```r
ar.mle(x, aic = TRUE, order.max = NULL, na.action = na.fail,
       demean = TRUE, series, ...)
## S3 method for class 'ar'
predict(object, newdata, n.ahead = 1, se.fit = TRUE, ...)
```

Arguments

- `x`: A univariate or multivariate time series.
- `aic`: Logical flag. If TRUE then the Akaike Information Criterion is used to choose the order of the autoregressive model. If FALSE, the model of order `order.max` is fitted.
- `order.max`: Maximum order (or order) of model to fit. Defaults to the smaller of \( N - 1 \) and \( 10 \log_{10}(N) \) where \( N \) is the number of observations except for `method = "mle"` where it is the minimum of this quantity and 12.
- `method`: Character string giving the method used to fit the model. Must be one of the strings in the default argument (the first few characters are sufficient). Defaults to "yule-walker".
- `na.action`: function to be called to handle missing values.
- `demean`: should a mean be estimated during fitting?
- `series`: names for the series. Defaults to `deparse(substitute(x))`.
- `var.method`: the method to estimate the innovations variance (see ‘Details’).
- `...`: additional arguments for specific methods.
- `object`: a fit from `ar`.
- `newdata`: data to which to apply the prediction.
n.ahead number of steps ahead at which to predict.

se.fit logical: return estimated standard errors of the prediction error?

Details

For definiteness, note that the AR coefficients have the sign in

\[ x_t - \mu = a_1(x_{t-1} - \mu) + \cdots + a_p(x_{t-p} - \mu) + e_t \]

ar is just a wrapper for the functions ar.yw, ar.burg, ar.ols and ar.mle.

Order selection is done by AIC if aic is true. This is problematic, as of the methods here only ar.mle performs true maximum likelihood estimation. The AIC is computed as if the variance estimate were the MLE, omitting the determinant term from the likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated parameter values. In ar.yw the variance matrix of the innovations is computed from the fitted coefficients and the autocovariance of x.

ar.burg allows two methods to estimate the innovations variance and hence AIC. Method 1 is to use the update given by the Levinson-Durbin recursion (Brockwell and Davis, 1991, (8.2.6) on page 242), and follows S-PLUS. Method 2 is the mean of the sum of squares of the forward and backward prediction errors (as in Brockwell and Davis, 1996, page 145). Percival and Walden (1998) discuss both. In the multivariate case the estimated coefficients will depend (slightly) on the variance estimation method.

Remember that ar includes by default a constant in the model, by removing the overall mean of x before fitting the AR model, or (ar.mle) estimating a constant to subtract.

Value

For ar and its methods a list of class "ar" with the following elements:

- order The order of the fitted model. This is chosen by minimizing the AIC if aic = TRUE, otherwise it is order.max.
- ar Estimated autoregression coefficients for the fitted model.
- var.pred The prediction variance: an estimate of the portion of the variance of the time series that is not explained by the autoregressive model.
- x.mean The estimated mean of the series used in fitting and for use in prediction.
- x.intercept (ar.ols only.) The intercept in the model for x - x.mean.
- aic The differences in AIC between each model and the best-fitting model. Note that the latter can have an AIC of -Inf.
- n.used The number of observations in the time series.
- order.max The value of the order.max argument.
- partialacf The estimate of the partial autocorrelation function up to lag order.max.
- resid residuals from the fitted model, conditioning on the first order observations. The first order residuals are set to NA. If x is a time series, so is resid.
- method The value of the method argument.
- series The name(s) of the time series.
- frequency The frequency of the time series.
- call The matched call.
- asy.var.coef (univariate case, order > 0.) The asymptotic-theory variance matrix of the coefficient estimates.

For predict.ar, a time series of predictions, or if se.fit = TRUE, a list with components pred, the predictions, and se, the estimated standard errors. Both components are time series.
**Note**

Only the univariate case of `ar.mle` is implemented. Fitting by `method="mle"` to long series can be very slow.

**Author(s)**

**Examples**

```r
ar(lh)
ar(lh, method = "burg")
ar(lh, method = "ols")
ar(lh, FALSE, 4) # fit ar(4)

(sunspot.ar <- ar(sunspot.year))
predict(sunspot.ar, n.ahead = 25)
## try the other methods too

ar(ts.union(BIsales, BJsales.lead))
## Burg is quite different here, as is OLS (see ar.mle)
ar(ts.union(BIsales, BJsales.lead), method = "burg")
```

---

**ar.mle**

Fit Autoregressive Models to Time Series by OLS

**Description**

Fit an autoregressive time series model to the data by ordinary least squares, by default selecting the complexity by AIC.
Usage

ar.ols(x, aic = TRUE, order.max = NULL, na.action = na.fail, 
    demean = TRUE, intercept = demean, series, ...)

Arguments

x
A univariate or multivariate time series.

aic
Logical flag. If TRUE then the Akaike Information Criterion is used to choose 
the order of the autoregressive model. If FALSE, the model of order order.max 
is fitted.

order.max
Maximum order (or order) of model to fit. Defaults to $10 \log_{10}(N)$ where $N$ is 
the number of observations.

na.action
function to be called to handle missing values.

demean
should the AR model be for x minus its mean?

intercept
should a separate intercept term be fitted?

series
names for the series. Defaults to deparse(substitute(x)).

... further arguments to be passed to or from methods.

Details

ar.ols fits the general AR model to a possibly non-stationary and/or multivariate system of series 
x. The resulting unconstrained least squares estimates are consistent, even if some of the series are 
non-stationary and/or co-integrated. For definiteness, note that the AR coefficients have the sign in

\[ x_t - \mu = a_0 + a_1 (x_{t-1} - \mu) + \cdots + a_p (x_{t-p} - \mu) + \epsilon_t \]

where $a_0$ is zero unless intercept is true, and $\mu$ is the sample mean if demean is true, zero other-
wise.

Order selection is done by AIC if aic is true. This is problematic, as ar.ols does not perform true maximum likelihood estimation. The AIC is computed as if the variance estimate (computed from the variance matrix of the residuals) were the MLE, omitting the determinant term from the likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated parameter values.

Some care is needed if intercept is true and demean is false. Only use this is the series are roughly centred on zero. Otherwise the computations may be inaccurate or fail entirely.

Value

A list of class "ar" with the following elements:

order
The order of the fitted model. This is chosen by minimizing the AIC if 
aic = TRUE, otherwise it is order.max.

ar
Estimated autoregression coefficients for the fitted model.

var.pred
The prediction variance: an estimate of the portion of the variance of the time 
series that is not explained by the autoregressive model.

x.mean
The estimated mean (or zero if demean is false) of the series used in fitting and 
for use in prediction.

x.intercept
The intercept in the model for x - x.mean, or zero if intercept is false.
The differences in AIC between each model and the best-fitting model. Note that the latter can have an AIC of $-\infty$.

The number of observations in the time series.

The value of the `order.max` argument.

NULL. For compatibility with `ar`.

residuals from the fitted model, conditioning on the first order observations. The first order residuals are set to `NA`. If `x` is a time series, so is `resid`.

The character string "Unconstrained LS".

The name(s) of the time series.

The frequency of the time series.

The matched call.

The asymptotic-theory standard errors of the coefficient estimates.

Adrian Trapletti, Brian Ripley.

Examples

```r
ar(1h, method = "burg")
ar.ols(1h)
ar.ols(1h, FALSE, 4)  # fit ar(4)
ar.ols(ts.union(BJsales, BJsales.lead))
x <- diff(log(EuStockMarkets))
ar.ols(x, order.max = 6, demean = FALSE, intercept = TRUE)
```
Usage

arima(x, order = c(0L, 0L, 0L),
    seasonal = list(order = c(0L, 0L, 0L), period = NA),
    xreg = NULL, include.mean = TRUE,
    transform.pars = TRUE,
    fixed = NULL, init = NULL,
    method = c("CSS-ML", "ML", "CSS"), n.cond,
    SSinit = c("Gardner1980", "Rougand2011"),
    optim.method = "BFGS",
    optim.control = list(), kappa = 1e6)

Arguments

x a univariate time series

order A specification of the non-seasonal part of the ARIMA model: the three integer components \((p, d, q)\) are the AR order, the degree of differencing, and the MA order.

seasonal A specification of the seasonal part of the ARIMA model, plus the period (which defaults to \text{frequency}(x)). This should be a list with components order and period, but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the order.

xreg Optionally, a vector or matrix of external regressors, which must have the same number of rows as \(x\).

include.mean Should the ARMA model include a mean/intercept term? The default is TRUE for undifferenced series, and it is ignored for ARIMA models with differencing.

transform.pars logical; if true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for \text{method} = "CSS". For \text{method} = "ML", it has been advantageous to set \text{transform.pars} = FALSE in some cases, see also fixed.

fixed optional numeric vector of the same length as the total number of parameters. If supplied, only \(NA\) entries in fixed will be varied. \text{transform.pars} = TRUE will be overridden (with a warning) if any AR parameters are fixed. It may be wise to set \text{transform.pars} = FALSE when fixing MA parameters, especially near non-invertibility.

init optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in fixed will be ignored.

method fitting method: maximum likelihood or minimize conditional sum-of-squares. The default (unless there are missing values) is to use conditional-sum-of-squares to find starting values, then maximum likelihood.

n.cond only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.

SSinit a string specifying the algorithm to compute the state-space initialization of the likelihood; see \text{KalmanLike} for details.

optim.method The value passed as the method argument to \text{optim}.

optim.control List of control parameters for \text{optim}.

kappa the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model. Do not reduce this.
Details

Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The
definition used here has

\[ X_t = a_1 X_{t-1} + \cdots + a_p X_{t-p} + \varepsilon_t + b_1 \varepsilon_{t-1} + \cdots + b_q \varepsilon_{t-q} \]

and so the MA coefficients differ in sign from those of S-PLUS. Further, if `include.mean` is true
(the default for an ARMA model), this formula applies to \( X - m \) rather than \( X \). For ARIMA
models with differencing, the differenced series follows a zero-mean ARMA model. If am `xreg`
term is included, a linear regression (with a constant term if `include.mean` is true and there is no
differencing) is fitted with an ARMA model for the error term.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may
only be a rough guide.

Optimization is done by `optim`. It will work best if the columns in `xreg` are roughly scaled to zero
mean and unit variance, but does attempt to estimate suitable scalings.

Value

A list of class "Arima" with components:

- `coef`: a vector of AR, MA and regression coefficients, which can be extracted by the `coef` method.
- `sigma2`: the MLE of the innovations variance.
- `var.coef`: the estimated variance matrix of the coefficients `coef`, which can be extracted
  by the `vcov` method.
- `loglik`: the maximized log-likelihood (of the differenced data), or the approximation to
  it used.
- `arma`: A compact form of the specification, as a vector giving the number of AR, MA,
  seasonal AR and seasonal MA coefficients, plus the period and the number of
  non-seasonal and seasonal differences.
- `aic`: the AIC value corresponding to the log-likelihood. Only valid for
  method = "ML" fits.
- `residuals`: the fitted innovations.
- `call`: the matched call.
- `series`: the name of the series `x`.
- `code`: the convergence value returned by `optim`.
- `n.cond`: the number of initial observations not used in the fitting.
- `model`: A list representing the Kalman Filter used in the fitting. See `KalmanLike`.

Fitting methods

The exact likelihood is computed via a state-space representation of the ARIMA process, and the
innovations and their variance found by a Kalman filter. The initialization of the differenced ARMA
process uses stationarity and is based on Gardner et al (1980). For a differenced process the non-
stationary components are given a diffuse prior (controlled by `kappa`). Observations which are still
controlled by the diffuse prior (determined by having a Kalman gain of at least \( 1 \epsilon 4 \)) are excluded
from the likelihood calculations. (This gives comparable results to `arima0` in the absence of missing
values, when the observations excluded are precisely those dropped by the differencing.)
Missing values are allowed, and are handled exactly in method "ML".

If `transform.pars` is true, the optimization is done using an alternative parametrization which is a variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p) model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure is applied (separately) to the AR and seasonal AR terms. The MA terms are not constrained to be invertible during optimization, but they will be converted to invertible form after optimization if `transform.pars` is true.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum of squares of the fitted innovations from observation `n.cond` on, (where `n.cond` is at least the maximum lag of an AR term), treating all earlier innovations to be zero. Argument `n.cond` can be used to allow comparability between different fits. The 'part log-likelihood' is the first term, half the log of the estimated mean square. Missing values are allowed, but will cause many of the innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.

Note

The results are likely to be different from S-PLUS’s `arima.mle`, which computes a conditional likelihood and does not include a mean in the model. Further, the convention used by `arima.mle` reverses the signs of the MA coefficients.

`arima` is very similar to `arima0` for ARMA models or for differenced models without missing values, but handles differenced models with missing values exactly. It is somewhat slower than `arima0`, particularly for seasonally differenced models.

`predict.Arima, arima.sim` for simulating from an ARIMA model, `tsdiag, arima0, ar`

Examples

```r
arima(lh, order = c(1,0,0))
arima(lh, order = c(3,0,0))
arima(lh, order = c(1,0,1))

arima(lh, order = c(3,0,0), method = "CSS")
```
Simulate from an ARIMA Model

Description

Simulate from an ARIMA model.

Usage

arima.sim(model, n, rand.gen = rnorm, innov = rand.gen(n, ...),
               n.start = NA, start.innov = rand.gen(n.start, ...),
               ...)

Arguments

model     A list with component ar and/or ma giving the AR and MA coefficients respectively. Optionally a component order can be used. An empty list gives an ARIMA(0, 0, 0) model, that is white noise.
n         length of output series, before un-differencing. A strictly positive integer.
rand.gen  optional: a function to generate the innovations.
innov     an optional times series of innovations. If not provided, rand.gen is used.
n.start   length of ‘burn-in’ period. If NA, the default, a reasonable value is computed.
start.innov an optional times series of innovations to be used for the burn-in period. If supplied there must be at least n.start values (and n.start is by default computed inside the function).
...        additional arguments for rand.gen. Most usefully, the standard deviation of the innovations generated by rnorm can be specified by sd.
Details

See \texttt{arima} for the precise definition of an ARIMA model.

The ARMA model is checked for stationarity.

ARIMA models are specified via the \texttt{order} component of \texttt{model}, in the same way as for \texttt{arima}. Other aspects of the \texttt{order} component are ignored, but inconsistent specifications of the MA and AR orders are detected. The un-differencing assumes previous values of zero, and to remind the user of this, those values are returned.

Random inputs for the ‘burn-in’ period are generated by calling \texttt{rand.gen}.

Value

A time-series object of class "ts".

See Also

\texttt{arima}

Examples

```r
require(graphics)

arima.sim(n = 63, list(ar = c(0.8897, -0.4858), ma = c(-0.2279, 0.2488)),
          sd = sqrt(0.1796))
# mildly long-tailed
arima.sim(n = 63, list(ar = c(0.8897, -0.4858), ma = c(-0.2279, 0.2488)),
          rand.gen = function(n, ...) sqrt(0.1796) * rt(n, df = 5))

# An ARIMA simulation
ts.sim <- arima.sim(list(order = c(1,1,0), ar = 0.7), n = 200)
ts.plot(ts.sim)
```

Description

Fit an ARIMA model to a univariate time series, and forecast from the fitted model.

Usage

```r
arima0(x, order = c(0, 0, 0),
       seasonal = list(order = c(0, 0, 0), period = NA),
       xreg = NULL, include.mean = TRUE, delta = 0.01,
       transform.pars = TRUE, fixed = NULL, init = NULL,
       method = c("ML", "CSS"), n.cond, optim.control = list())
```

### S3 method for class 'arima0'
predict(object, n.ahead = 1, newxreg, se.fit = TRUE, ...)
Arguments

x          a univariate time series
order      A specification of the non-seasonal part of the ARIMA model: the three components \((p, d, q)\) are the AR order, the degree of differencing, and the MA order.
seasonal   A specification of the seasonal part of the ARIMA model, plus the period (which defaults to \(\text{frequency}(x)\)). This should be a list with components \(\text{order}\) and \(\text{period}\), but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the order.
xreg       Optionally, a vector or matrix of external regressors, which must have the same number of rows as \(x\).
include.mean Should the ARIMA model include a mean term? The default is \text{TRUE} for undifferenced series, \text{FALSE} for differenced ones (where a mean would not affect the fit nor predictions).
delta      A value to indicate at which point ‘fast recursions’ should be used. See the ‘Details’ section.
transform.pars Logical. If true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for \text{method = "CSS"}.
fixed      optional numeric vector of the same length as the total number of parameters. If supplied, only \(NA\) entries in \text{fixed} will be varied. \text{transform.pars = TRUE} will be overridden (with a warning) if any ARMA parameters are fixed.
init       optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in \text{fixed} will be ignored.
method     Fitting method: maximum likelihood or minimize conditional sum-of-squares.
n.cond     Only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.
optim.control List of control parameters for \text{optim}.
object     The result of an \text{arima0} fit.
nwreg      New values of \text{xreg} to be used for prediction. Must have at least \text{n.ahead} rows.
n.ahead    The number of steps ahead for which prediction is required.
se.fit     Logical: should standard errors of prediction be returned?
...        arguments passed to or from other methods.

Details

Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The definition here has

\[
X_t = a_1 X_{t-1} + \cdots + a_p X_{t-p} + \epsilon_t + b_1 \epsilon_{t-1} + \cdots + b_q \epsilon_{t-q}
\]

and so the MA coefficients differ in sign from those of S-PLUS. Further, if \text{include.mean} is true, this formula applies to \(X - m\) rather than \(X\). For ARIMA models with differencing, the differenced series follows a zero-mean ARMA model.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may only be a rough guide, especially for fits close to the boundary of invertibility.
Optimization is done by `optim`. It will work best if the columns in `xreg` are roughly scaled to zero mean and unit variance, but does attempt to estimate suitable scalings.

Finite-history prediction is used. This is only statistically efficient if the MA part of the fit is invertible, so `predict.arima0` will give a warning for non-invertible MA models.

Value

For `arima0`, a list of class "arima0" with components:

- `coef`: a vector of AR, MA and regression coefficients,
- `sigma2`: the MLE of the innovations variance.
- `var.coef`: the estimated variance matrix of the coefficients `coef`.
- `loglik`: the maximized log-likelihood (of the differenced data), or the approximation to if used.
- `arma`: A compact form of the specification, as a vector giving the number of AR, MA, seasonal AR and seasonal MA coefficients, plus the period and the number of non-seasonal and seasonal differences.
- `aic`: the AIC value corresponding to the log-likelihood. Only valid for method = "ML" fits.
- `residuals`: the fitted innovations.
- `call`: the matched call.
- `series`: the name of the series `x`.
- `convergence`: the value returned by `optim`.
- `n.cond`: the number of initial observations not used in the fitting.

For `predict.arima0`, a time series of predictions, or if `se.fit = TRUE`, a list with components `pred`, the predictions, and `se`, the estimated standard errors. Both components are time series.

Fitting methods

The exact likelihood is computed via a state-space representation of the ARMA process, and the innovations and their variance found by a Kalman filter based on Gardner et al (1980). This has the option to switch to 'fast recursions' (assume an effectively infinite past) if the innovations variance is close enough to its asymptotic bound. The argument `delta` sets the tolerance: at its default value the approximation is normally negligible and the speed-up considerable. Exact computations can be ensured by setting `delta` to a negative value.

If `transform.pars` is true, the optimization is done using an alternative parametrization which is a variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p) model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure is applied (separately) to the AR and seasonal AR terms. The MA terms are also constrained to be invertible during optimization by the same transformation if `transform.pars` is true. Note that the MLE for MA terms does sometimes occur for MA polynomials with unit roots: such models can be fitted by using `transform.pars = FALSE` and specifying a good set of initial values (often obtainable from a fit with `transform.pars = TRUE`).

Missing values are allowed, but any missing values will force `delta` to be ignored and full recursions used. Note that missing values will be propagated by differencing, so the procedure used in this function is not fully efficient in that case.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum of squares of the fitted innovations from observation `n.cond` on, (where `n.cond` is at least the
maximum lag of an AR term), treating all earlier innovations to be zero. Argument \texttt{n.cond} can be used to allow comparability between different fits. The ‘part log-likelihood’ is the first term, half the log of the estimated mean square. Missing values are allowed, but will cause many of the innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.

\textbf{Note}

This is a preliminary version, and will be replaced by \texttt{arima}.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients.

The results are likely to be different from S-PLUS's \texttt{arima.mle}, which computes a conditional likelihood and does not include a mean in the model. Further, the convention used by \texttt{arima.mle} reverses the signs of the MA coefficients.

tsdia(fit1)
```
Compute Theoretical ACF for an ARMA Process

Description

Compute the theoretical autocorrelation function or partial autocorrelation function for an ARMA process.

Usage

```
armaacf(ar = numeric(), ma = numeric(), lag.max = r, pacf = FALSE)
```

Arguments

- `ar` numeric vector of AR coefficients
- `ma` numeric vector of MA coefficients
- `lag.max` integer. Maximum lag required. Defaults to `max(p, q)`, where `p`, `q` are the numbers of AR and MA terms respectively.
- `pacf` logical. Should the partial autocorrelations be returned?

Details

The methods used follow Brockwell & Davis (1991, section 3.3). Their equations (3.3.8) are solved for the autocovariances at lags 0, \ldots, \text{max}(p, q+1), and the remaining autocorrelations are given by a recursive filter.

Value

A vector of (partial) autocorrelations, named by the lags.

**ARMAtoMA**  
Convert ARMA Process to Infinite MA Process

**Description**

Convert ARMA process to infinite MA process.

**Usage**

ARMAtoMA(ar = numeric(), ma = numeric(), lag.max)

**Arguments**

- **ar**: numeric vector of AR coefficients
- **ma**: numeric vector of MA coefficients
- **lag.max**: Largest MA(Inf) coefficient required.

**Value**

A vector of coefficients.

**References**

Springer.

\]
as.hclust

Convert Objects to Class hclust

Description

Converts objects from other hierarchical clustering functions to class "hclust".

Usage

as.hclust(x, ...)

Arguments

x Hierarchical clustering object

... further arguments passed to or from other methods.

Details

Currently there is only support for converting objects of class "twins" as produced by the functions diana and agnes from the package cluster. The default method throws an error unless passed a "hclust" object.

Value

An object of class "hclust".

See Also

hclust, and from package cluster, diana and agnes

Examples

x <- matrix(rnorm(30), ncol = 3)
hc <- hclust(dist(x), method = "complete")
if(require("cluster", quietly = TRUE)) { # is a recommended package
  ag <- agnes(x, method = "complete")
  htag <- as.hclust(ag)
  # The dendrograms order slightly differently:
  op <- par(mfrow = c(1,2))
  plot(hc); mtext("hclust", side = 1)
  plot(htag); mtext("agnes", side = 1)
  detach("package:cluster")
}
asOneSidedFormula  

Convert to One-Sided Formula

Description

Names, expressions, numeric values, and character strings are converted to one-sided formulae. If object is a formula, it must be one-sided, in which case it is returned unaltered.

Usage

asOneSidedFormula(object)

Arguments

object    a one-sided formula, an expression, a numeric value, or a character string.

Value

a one-sided formula representing object

Author(s)

José Pinheiro and Douglas Bates

See Also

formula

Examples

asOneSidedFormula("age")
asOneSidedFormula(~ age)

ave  

Group Averages Over Level Combinations of Factors

Description

Subsets of x[] are averaged, where each subset consist of those observations with the same factor levels.

Usage

ave(x, ..., FUN = mean)

Arguments

x    A numeric.
...
Grouping variables, typically factors, all of the same length as x.
FUN  Function to apply for each factor level combination.
Value

A numeric vector, say \( y \) of length \( \text{length}(x) \). If \( \ldots \) is equal to \( \text{FUN}(x[j], \ldots) \), for all \( j \) with \( g1[j] == g1[i] \) and \( g2[j] == g2[i] \).

See Also

\texttt{mean, median}.

Examples

```
require(graphics)

ave(1:3) # no grouping -> grand mean

attach(warpbreaks)
ave(breaks, wool)
ave(breaks, tension)
ave(breaks, tension, FUN = function(x) mean(x, trim = 0.1))
plot(breaks, main =
  "ave(Warpbreaks) for wool x tension combinations")
lines(ave(breaks, wool, tension ), type = "s", col = "blue")
lines(ave(breaks, wool, tension, FUN = median), type = "s", col = "green")
legend(40, 70, c("mean", "median"), lty = 1,
  col = c("blue", "green"), bg = "gray90")
```

Description

Bandwidth selectors for Gaussian kernels in \texttt{density}.

Usage

```
bw.nrd0(x)
bw.nrd(x)
bw.ucv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax,
  tol = 0.1 * lower)
bw.bcv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax,
  tol = 0.1 * lower)
bw.SJ(x, nb = 1000, lower = 0.1 * hmax, upper = hmax,
  method = c("ste", "dpi"), tol = 0.1 * lower)
```
bandwidth

Arguments

- **x**: numeric vector.
- **nb**: number of bins to use.
- **lower, upper**: range over which to minimize. The default is almost always satisfactory. hmax is calculated internally from a normal reference bandwidth.
- **method**: either "ste" ("solve-the-equation") or "dpi" ("direct plug-in").
- **tol**: for method "ste", the convergence tolerance for uniroot. The default leads to bandwidth estimates with only slightly more than one digit accuracy, which is sufficient for practical density estimation, but possibly not for theoretical simulation studies.

Details

bw.nrd0 implements a rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator. It defaults to 0.9 times the minimum of the standard deviation and the interquartile range divided by 1.34 times the sample size to the negative one-fifth power (= Silverman’s ‘rule of thumb’. Silverman (1986, page 48, eqn (3.31)) unless the quartiles coincide when a positive result will be guaranteed.

bw.nrd is the more common variation given by Scott (1992), using factor 1.06.

bw.ucv and bw.bcv implement unbiased and biased cross-validation respectively.

bw.SJ implements the methods of Sheather & Jones (1991) to select the bandwidth using pilot estimation of derivatives. The algorithm for method "ste" solves an equation (via uniroot) and because of that, enlarges the interval c(lower, upper) when the boundaries were not user-specified and do not bracket the root.

Value

A bandwidth on a scale suitable for the bw argument of density.

References

See Also

density.

bandwidth.nrd, ucv, bcv and width.SJ in package MASS, which are all scaled to the width argument of density and so give answers four times as large.
Examples

```
require(graphics)

plot(density(precip, n = 1000))
rug(density(precip))
lines(density(precip, bw = "nrd"), col = 2)
lines(density(precip, bw = "ucv"), col = 3)
lines(density(precip, bw = "bcv"), col = 4)
lines(density(precip, bw = "SJ-ste"), col = 5)
lines(density(precip, bw = "SJ-dpi"), col = 6)
legend(55, 0.035,
      legend = c("nrd0", "nrd", "ucv", "bcv", "SJ-ste", "SJ-dpi"),
      col = 1:6, lty = 1)
```

bartlett.test  

**Bartlett Test of Homogeneity of Variances**

Description

Performs Bartlett’s test of the null that the variances in each of the groups (samples) are the same.

Usage

```
bartlett.test(x, ...)

## Default S3 method:
bartlett.test(x, g, ...)

## S3 method for class 'formula'
bartlett.test(formula, data, subset, na.action, ...)
```

Arguments

- `x` a numeric vector of data values, or a list of numeric data vectors representing the respective samples, or fitted linear model objects (inheriting from class "lm").
- `g` a vector or factor object giving the group for the corresponding elements of `x`. Ignored if `x` is a list.
- `formula` a formula of the form `lhs ~ rhs` where `lhs` gives the data values and `rhs` the corresponding groups.
- `data` an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- `subset` an optional vector specifying a subset of observations to be used.
- `na.action` a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- `...` further arguments to be passed to or from methods.
Details

If `x` is a list, its elements are taken as the samples or fitted linear models to be compared for homogeneity of variances. In this case, the elements must either all be numeric data vectors or fitted linear model objects, `g` is ignored, and one can simply use `bartlett.test(x)` to perform the test. If the samples are not yet contained in a list, use `bartlett.test(list(x, ...))`. Otherwise, `x` must be a numeric data vector, and `g` must be a vector or factor object of the same length as `x` giving the group for the corresponding elements of `x`.

Value

A list of class "htest" containing the following components:

- `statistic`: Bartlett's K-squared test statistic.
- `parameter`: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- `p.value`: the p-value of the test.
- `method`: the character string "Bartlett test of homogeneity of variances".
- `data.name`: a character string giving the names of the data.

References

See Also

- `var.test` for the special case of comparing variances in two samples from normal distributions;
- `fligner.test` for a rank-based (nonparametric) k-sample test for homogeneity of variances;
- `ansari.test` and `mood.test` for two rank based two-sample tests for difference in scale.

Examples

```r
require(graphics)
plot(count ~ spray, data = InsectSprays)
bartlett.test(InsectSprays$count, InsectSprays$spray)
bartlett.test(count ~ spray, data = InsectSprays)
```

---

**Beta**

The Beta Distribution

Description

Density, distribution function, quantile function and random generation for the Beta distribution with parameters `shape1` and `shape2` (and optional non-centrality parameter `ncp`).

Usage

- `dbeta(x, shape1, shape2, ncp = 0, log = FALSE)`
- `pbeta(q, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)`
- `qbeta(p, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)`
- `rbeta(n, shape1, shape2, ncp = 0)`
Arguments

- `x, q`: vector of quantiles.
- `p`: vector of probabilities.
- `n`: number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `shape1, shape2`: non-negative parameters of the Beta distribution.
- `ncp`: non-centrality parameter.
- `log, log.p`: logical; if TRUE, probabilities `p` are given as `log(p)`.
- `lower.tail`: logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The Beta distribution with parameters \( \text{shape1} = a \) and \( \text{shape2} = b \) has density

\[
f(x) = \frac{\Gamma(a + b)}{\Gamma(a)\Gamma(b)} x^{a-1}(1 - x)^{b-1}
\]

for \( a > 0, b > 0 \) and \( 0 \leq x \leq 1 \) where the boundary values at \( x = 0 \) or \( x = 1 \) are defined as by continuity (as limits).
The mean is \( a/(a + b) \) and the variance is \( ab/(a + b)^2(a + b + 1) \). These moments and all distributional properties can be defined as limits (leading to point masses at 0, 1/2, or 1) when \( a \) or \( b \) are zero or infinite, and the corresponding \([dpqr]beta()\) functions are defined correspondingly.

\( \text{pbeta} \) is closely related to the incomplete beta function. As defined by Abramowitz and Stegun 6.6.1

\[
B_x(a, b) = \int_0^x t^{a-1}(1 - t)^{b-1}dt,
\]

and 6.6.2 \( I_x(a, b) = B_x(a, b)/B(a, b) \) where \( B(a, b) = B_1(a, b) \) is the Beta function (\text{beta}).

\( I_x(a, b) \) is \( \text{pbeta}(x, a, b) \).

The noncentral Beta distribution (with \( \text{ncp} = \lambda \)) is defined (Johnson et al, 1995, pp. 502) as the distribution of \( X/(X + Y) \) where \( X \sim \chi^2_{2a}(\lambda) \) and \( Y \sim \chi^2_{2b} \).

Value

\( \text{dbeta} \) gives the density, \( \text{pbeta} \) the distribution function, \( \text{qbeta} \) the quantile function, and \( \text{rbeta} \) generates random deviates.

Invalid arguments will result in return value \( \text{NaN} \), with a warning.

The length of the result is determined by \( n \) for \( \text{rbeta} \), and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

Supplying \( \text{ncp} = 0 \) uses the algorithm for the non-central distribution, which is not the same algorithm used if \( \text{ncp} \) is omitted. This is to give consistent behaviour in extreme cases with values of \( \text{ncp} \) very near zero.
The central \( \text{dbeta} \) is based on a binomial probability, using code contributed by Catherine Loader (see \texttt{dbinom}) if either shape parameter is larger than one, otherwise directly from the definition. The non-central case is based on the derivation as a Poisson mixture of betas (Johnson \textit{et al}, 1995, pp. 502–3).

This computes the lower tail only, so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant.

References

See Also

\texttt{Distributions} for other standard distributions.
\texttt{beta} for the Beta function.

Examples

\begin{verbatim}
x <- seq(0, 1, length = 21)
dbeta(x, 1, 1)
pbeta(x, 1, 1)

## Visualization, including limit cases:
pl.beta <- function(a,b, asp = if(isLim) 1, ylim = if(isLim) c(0,1.1)) {
  if(isLim <- a == 0 || b == 0 || a == Inf || b == Inf) {
    eps <- 1e-10
    x <- c(0, eps, (1:7)/16, 1/2+c(-eps,0,eps), (9:15)/16, 1-eps, 1)
  } else {

```
binom.test

Description

Performs an exact test of a simple null hypothesis about the probability of success in a Bernoulli experiment.

Usage

```r
binom.test(x, n, p = 0.5, 
    alternative = c("two.sided", "less", "greater"), 
    conf.level = 0.95)
```

Arguments

- `x` number of successes, or a vector of length 2 giving the numbers of successes and failures, respectively.
- `n` number of trials; ignored if `x` has length 2.
- `p` hypothesized probability of success.
- `alternative` indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
- `conf.level` confidence level for the returned confidence interval.
Details

Confidence intervals are obtained by a procedure first given in Clopper and Pearson (1934). This guarantees that the confidence level is at least conf.level, but in general does not give the shortest-length confidence intervals.

Value

A list with class "htest" containing the following components:

- statistic: the number of successes.
- parameter: the number of trials.
- p.value: the p-value of the test.
- conf.int: a confidence interval for the probability of success.
- estimate: the estimated probability of success.
- null.value: the probability of success under the null, p.
- alternative: a character string describing the alternative hypothesis.
- method: the character string "Exact binomial test".
- data.name: a character string giving the names of the data.

References

See Also

prop.test for a general (approximate) test for equal or given proportions.

Examples

```r
## Under (the assumption of) simple Mendelian inheritance, a cross
## between plants of two particular genotypes produces progeny 1/4 of
## which are "dwarf" and 3/4 of which are "giant", respectively.
## In an experiment to determine if this assumption is reasonable, a
## cross results in progeny having 243 dwarf and 682 giant plants.
## If "giant" is taken as success, the null hypothesis is that p =
binom.test(c(682, 243), p = 3/4)  # The same.
## => Data are in agreement with the null hypothesis.
```
Binomial

The Binomial Distribution

Description
Density, distribution function, quantile function and random generation for the binomial distribution with parameters size and prob.
This is conventionally interpreted as the number of 'successes' in size trials.

Usage
\[ \text{dbinom}(x, \text{size}, \text{prob}, \log = \text{FALSE}) \]
\[ \text{pbinom}(q, \text{size}, \text{prob}, \text{lower.tail} = \text{TRUE}, \log.p = \text{FALSE}) \]
\[ \text{qbinom}(p, \text{size}, \text{prob}, \text{lower.tail} = \text{TRUE}, \log.p = \text{FALSE}) \]
\[ \text{rbinom}(n, \text{size}, \text{prob}) \]

Arguments
- \( x, q \): vector of quantiles.
- \( p \): vector of probabilities.
- \( n \): number of observations. If \( \text{length}(n) > 1 \), the length is taken to be the number required.
- \( \text{size} \): number of trials (zero or more).
- \( \text{prob} \): probability of success on each trial.
- \( \log, \log.p \): logical; if TRUE, probabilities \( p \) are given as \( \log(p) \).
- \( \text{lower.tail} \): logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details
The binomial distribution with size = \( n \) and prob = \( p \) has density

\[ p(x) = \binom{n}{x} p^x (1 - p)^{n-x} \]

for \( x = 0, \ldots, n \). Note that binomial coefficients can be computed by `choose` in R.
If an element of \( x \) is not integer, the result of `dbinom` is zero, with a warning.
\( p(x) \) is computed using Loader’s algorithm, see the reference below.
The quantile is defined as the smallest value \( x \) such that \( F(x) \geq p \), where \( F \) is the distribution function.

Value
`dbinom` gives the density, `pbinom` gives the distribution function, `qbinom` gives the quantile function and `rbinom` generates random deviates.
If size is not an integer, NaN is returned.
The length of the result is determined by \( n \) for `rbinom`, and is the maximum of the lengths of the numerical arguments for the other functions.
The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.
Source

For dbinom a saddle-point expansion is used: see
Catherine Loader (2000). Fast and Accurate Computation of Binomial Probabilities; available from

pbinom uses pbeta.

qbinom uses the Cornish–Fisher Expansion to include a skewness correction to a normal approxi-
mation, followed by a search.

rbinom (for size < .Machine$integer.max) is based on
ications of the ACM, 31, 216–222.

For larger values it uses inversion.

See Also

Distributions for other standard distributions, including dnbinom for the negative binomial, and
dpois for the Poisson distribution.

Examples

require(graphics)
# Compute P(45 < X < 55) for X Binomial(100, 0.5)
sum(dbinom(46:54, 100, 0.5))

## Using "log = TRUE" for an extended range :
set <- 2000
k <- seq(0, n, by = 20)
plot (k, dbinom(k, n, pi/10, log = TRUE), type = "l", ylab = "log density",
main = "dbinom(*, log=TRUE) is better than log(dbinom(*))")
lines (k, log(dbinom(k, n, pi/10)), col = "red", lwd = 2)
## extreme points are omitted since dbinom gives 0.

## Extended range

## arrow

## title

biplot

Biplot of Multivariate Data

Description

Plot a biplot on the current graphics device.

Usage

biplot(x, ...)

## Default S3 method:

biplot(x, y, var.axes = TRUE, col, cex = rep(par("cex"), 2),
xlab = NULL, ylab = NULL, expand = 1,
xlim = NULL, ylim = NULL, arrow.len = 0.1,
main = NULL, sub = NULL, xlab = NULL, ylab = NULL, ...)
Arguments

- **x**: The biplot, a fitted object. For `biplot.default`, the first set of points (a two-column matrix), usually associated with observations.
- **y**: The second set of points (a two-column matrix), usually associated with variables.
- **var.axes**: If `TRUE` the second set of points have arrows representing them as (unscaled) axes.
- **col**: A vector of length 2 giving the colours for the first and second set of points respectively (and the corresponding axes). If a single colour is specified it will be used for both sets. If missing the default colour is looked for in the `palette`: if there it and the next colour as used, otherwise the first two colours of the palette are used.
- **cex**: The character expansion factor used for labelling the points. The labels can be of different sizes for the two sets by supplying a vector of length two.
- **xlabs**: A vector of character strings to label the first set of points: the default is to use the row dimname of `x`, or `1:n` if the dimname is `NULL`.
- **ylabs**: A vector of character strings to label the second set of points: the default is to use the row dimname of `y`, or `1:n` if the dimname is `NULL`.
- **expand**: An expansion factor to apply when plotting the second set of points relative to the first. This can be used to tweak the scaling of the two sets to a physically comparable scale.
- **arrow.len**: The length of the arrow heads on the axes plotted in `var.axes` is true. The arrow head can be suppressed by `arrow.len = 0`.
- **xlim, ylim**: Limits for the x and y axes in the units of the first set of variables.
- **main, sub, xlab, ylab, ...**: Graphical parameters.

Details

A biplot is plot which aims to represent both the observations and variables of a matrix of multivariate data on the same plot. There are many variations on biplots (see the references) and perhaps the most widely used one is implemented by `biplot.princomp`. The function `biplot.default` merely provides the underlying code to plot two sets of variables on the same figure.

Graphical parameters can also be given to `biplot`: the size of `xlabs` and `ylabs` is controlled by `cex`.

Side Effects

- A plot is produced on the current graphics device.

References

See Also

- `biplot.princomp`, also for examples.
Description

Produces a biplot (in the strict sense) from the output of `princomp` or `prcomp`.

Usage

```r
## S3 method for class 'prcomp'
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)

## S3 method for class 'princomp'
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)
```

Arguments

- `x` an object of class "princomp".
- `choices` length 2 vector specifying the components to plot. Only the default is a biplot in the strict sense.
- `scale` The variables are scaled by \( \lambda^\text{scale} \) and the observations are scaled by \( \lambda \times (1-\text{scale}) \) where \( \lambda \) are the singular values as computed by `princomp`. Normally \( 0 \leq \text{scale} \leq 1 \), and a warning will be issued if the specified scale is outside this range.
- `pc.biplot` If true, use what Gabriel (1971) refers to as a "principal component biplot", with \( \lambda \) and observations scaled up by \( \sqrt{n} \) and variables scaled down by \( \sqrt{n} \). Then inner products between variables approximate covariances and distances between observations approximate Mahalanobis distance.
- `...` optional arguments to be passed to `biplot.default`.

Details

This is a method for the generic function `biplot`. There is considerable confusion over the precise definitions: those of the original paper, Gabriel (1971), are followed here. Gabriel and Odoroff (1990) use the same definitions, but their plots actually correspond to `pc.biplot = TRUE`.

Side Effects

A plot is produced on the current graphics device.

Examples

```R
require(graphics)
biplot(princomp(USArrests))
```

<table>
<thead>
<tr>
<th>birthday</th>
<th>Probability of coincidences</th>
</tr>
</thead>
</table>

Description

Computes answers to a generalised *birthday paradox* problem. `pbirthday` computes the probability of a coincidence and `qbirthday` computes the smallest number of observations needed to have at least a specified probability of coincidence.

Usage

```R
qbirthday(prob = 0.5, classes = 365, coincident = 2)
pbirthday(n, classes = 365, coincident = 2)
```

Arguments

- `classes` How many distinct categories the people could fall into
- `prob` The desired probability of coincidence
- `n` The number of people
- `coincident` The number of people to fall in the same category

Details

The birthday paradox is that a very small number of people, 23, suffices to have a 50–50 chance that two or more of them have the same birthday. This function generalises the calculation to probabilities other than 0.5, numbers of coincident events other than 2, and numbers of classes other than 365.

The formula used is approximate for `coincident > 2`. The approximation is very good for moderate values of `prob` but less good for very small probabilities.

Value

- `qbirthday` Minimum number of people needed for a probability of at least `prob` that `k` or more of them have the same one out of `classes` equiprobable labels.
- `pbirthday` Probability of the specified coincidence.

References

Box.test  

Examples

```r
require(graphics)

## the standard version
qbirthday() # 23
## probability of > 2 people with the same birthday
qbirthday(23, coincident = 3)

## examples from Diaconis & Mosteller p. 858.
## 'coincidence' is that husband, wife, daughter all born on the 16th
qbirthday(classes = 30, coincident = 3) # approximately 18
qbirthday(coincident = 4) # exact value 187
qbirthday(coincident = 10) # exact value 1181

## same 4-digit PIN number
qbirthday(classes = 10^4)

## 0.9 probability of three or more coincident birthdays
qbirthday(coincident = 3, prob = 0.9)

## Chance of 4 or more coincident birthdays in 150 people
qbirthday(150, coincident = 4)

## 100 or more coincident birthdays in 1000 people: very rare
qbirthday(1000, coincident = 100)
```

Description

Compute the Box–Pierce or Ljung–Box test statistic for examining the null hypothesis of independence in a given time series. These are sometimes known as ‘portmanteau’ tests.

Usage

```r
Box.test(x, lag = 1, type = c("Box-Pierce", "Ljung-Box"), fitdf = 0)
```

Arguments

- `x`: a numeric vector or univariate time series.
- `lag`: the statistic will be based on lag autocorrelation coefficients.
- `type`: test to be performed: partial matching is used.
- `fitdf`: number of degrees of freedom to be subtracted if `x` is a series of residuals.

Details

These tests are sometimes applied to the residuals from an ARMA(p, q) fit, in which case the references suggest a better approximation to the null-hypothesis distribution is obtained by setting `fitdf = p+q`, provided of course that `lag > fitdf`. 

Box.test  

Box-Pierce and Ljung-Box Tests
Value

A list with class "htest" containing the following components:

- **statistic**: the value of the test statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic (taking fitdf into account).
- **p.value**: the p-value of the test.
- **method**: a character string indicating which type of test was performed.
- **data.name**: a character string giving the name of the data.

Note

Missing values are not handled.

Author(s)

A. Trapletti

References

Examples

```r
x <- rnorm(100)
Box.test(x, lag = 1)
Box.test(x, lag = 1, type = "Ljung")
```

Sets Contrasts for a Factor

Description

Sets the "contrasts" attribute for the factor.

Usage

```r
C(object, contr, how.many, ...)
```

Arguments

- **object**: a factor or ordered factor
- **contr**: which contrasts to use. Can be a matrix with one row for each level of the factor or a suitable function like `contr.poly` or a character string giving the name of the function
- **how.many**: the number of contrasts to set, by default one less than `nlevels(object)`
- **...**: additional arguments for the function `contr`. 
cancor

Details

For compatibility with S, contr can be treatment, helmert, sum or poly (without quotes) as shorthand for contr.treatment and so on.

Value

The factor object with the "contrasts" attribute set.

References

See Also

contrasts, contr.sum, etc.

Examples

## reset contrasts to defaults
options(contrasts = c("contr.treatment", "contr.poly"))
tens <- with(warpbreaks, C(tension, poly, 1))
attributes(tens)
## tension SHOULD be an ordered factor, but as it is not we can use
aov(breaks ~ wool + tens + tension, data = warpbreaks)

## show the use of ... The default contrast is contr.treatment here
summary(lm(breaks ~ wool + C(tension, base = 2), data = warpbreaks))

# following on from help(esoph)
model3 <- glm(cbind(ncases, ncontrols) ~ agegp + C(tobgp, , 1) +
  C(alcgp, , 1), data = esoph, family = binomial())
summary(model3)

cancor  Canonical Correlations

Description

Compute the canonical correlations between two data matrices.

Usage

cancor(x, y, xcenter = TRUE, ycenter = TRUE)

Arguments

x numeric matrix ($n \times p_1$), containing the x coordinates.
y numeric matrix ($n \times p_2$), containing the y coordinates.
xcenter logical or numeric vector of length $p_1$, describing any centering to be done on the x values before the analysis. If `TRUE` (default), subtract the column means. If `FALSE`, do not adjust the columns. Otherwise, a vector of values to be subtracted from the columns.

ycenter analogous to xcenter, but for the y values.

Details

The canonical correlation analysis seeks linear combinations of the y variables which are well explained by linear combinations of the x variables. The relationship is symmetric as ‘well explained’ is measured by correlations.

Value

A list containing the following components:

- `cor` correlations.
- `xcoef` estimated coefficients for the x variables.
- `ycoef` estimated coefficients for the y variables.
- `xcenter` the values used to adjust the x variables.
- `ycenter` the values used to adjust the x variables.

References

See Also

`qr`, `svd`.

Examples

```r
## signs of results are random
pop <- LifeCycleSavings[, 2:3]
oec <- LifeCycleSavings[, -(2:3)]
cancor(pop, oec)

x <- matrix(rnorm(150), 50, 3)
y <- matrix(rnorm(250), 50, 5)
(cxy <- cancor(x, y))
all(abs(cor(x %x% cxy$xcoef, y %x% cxy$ycoef))[,1:3] - diag(cxy $ cor)) < 1e-15
all(abs(cor(x %x% cxy$xcoef) - diag(3)) < 1e-15)
all(abs(cor(y %x% cxy$ycoef) - diag(5)) < 1e-15)
```
Case and Variable Names of Fitted Models

Description

Simple utilities returning (non-missing) case names, and (non-eliminated) variable names.

Usage

case.names(object, ...)

## S3 method for class 'lm'
case.names(object, full = FALSE, ...)

variable.names(object, ...)

## S3 method for class 'lm'
variable.names(object, full = FALSE, ...)

Arguments

object  an \texttt{R} object, typically a fitted model.

full  logical; if \texttt{TRUE}, all names (including zero weights, \ldots) are returned.

...  further arguments passed to or from other methods.

Value

A character vector.

See Also

\texttt{lm}; further, \texttt{all.names}, \texttt{all.vars} for functions with a similar name but only slightly related purpose.

Examples

x <- 1:20
y <- setNames(x + (x/4 - 2)^3 + rnorm(20, sd = 3),
paste("O", x, sep = ".")
ww <- rep(1, 20); ww[13] <- 0
summary(lmxy <- lm(y ~ x + I(x^2)+I(x^3) + I((x-10)^2), weights = ww),
cor = \texttt{TRUE})
variable.names(lmxy)
variable.names(lmxy, full = \texttt{TRUE})  # includes the last
case.names(lmxy)
case.names(lmxy, full = \texttt{TRUE})  # includes the 0-weight case
The Cauchy Distribution

Description

Density, distribution function, quantile function and random generation for the Cauchy distribution with location parameter location and scale parameter scale.

Usage

dcauchy(x, location = 0, scale = 1, log = FALSE)
pcauchy(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qcauchy(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rcauchy(n, location = 0, scale = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
location, scale location and scale parameters.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are P[X \leq x], otherwise, P[X > x].

Details

If location or scale are not specified, they assume the default values of 0 and 1 respectively.
The Cauchy distribution with location \( l \) and scale \( s \) has density
\[ f(x) = \frac{1}{\pi s} \left(1 + \left(\frac{x - l}{s}\right)^2\right)^{-1} \]
for all \( x \).

Value

dcauchy, pcauchy, and qcauchy are respectively the density, distribution function and quantile function of the Cauchy distribution. rcauchy generates random deviates from the Cauchy.
The length of the result is determined by n for rcauchy, and is the maximum of the lengths of the numerical arguments for the other functions.
The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Source

dcauchy, pcauchy and qcauchy are all calculated from numerically stable versions of the definitions.
rcauchy uses inversion.
References

See Also

*Distributions* for other standard distributions, including `dt` for the t distribution which generalizes `dcauchy(x, 1 = 0, s = 1)`.

Examples

dcauchy(-1:4)

---

**chisq.test**

*Pearson’s Chi-squared Test for Count Data*

**Description**

`chisq.test` performs chi-squared contingency table tests and goodness-of-fit tests.

**Usage**

```r
chisq.test(x, y = NULL, correct = TRUE, 
            p = rep(1/length(x), length(x)), rescale.p = FALSE, 
            simulate.p.value = FALSE, B = 2000)
```

**Arguments**

- `x` a numeric vector or matrix. `x` and `y` can also both be factors.
- `y` a numeric vector; ignored if `x` is a matrix. If `x` is a factor, `y` should be a factor of the same length.
- `correct` a logical indicating whether to apply continuity correction when computing the test statistic for 2 by 2 tables: one half is subtracted from all `|O − E|` differences; however, the correction will not be bigger than the differences themselves. No correction is done if `simulate.p.value = TRUE`.
- `p` a vector of probabilities of the same length of `x`. An error is given if any entry of `p` is negative.
- `rescale.p` a logical scalar; if TRUE then `p` is rescaled (if necessary) to sum to 1. If `rescale.p` is FALSE, and `p` does not sum to 1, an error is given.
- `simulate.p.value` a logical indicating whether to compute p-values by Monte Carlo simulation.
- `B` an integer specifying the number of replicates used in the Monte Carlo test.
Details

If \( x \) is a matrix with one row or column, or if \( x \) is a vector and \( y \) is not given, then a goodness-of-fit test is performed (\( x \) is treated as a one-dimensional contingency table). The entries of \( x \) must be non-negative integers. In this case, the hypothesis tested is whether the population probabilities equal those in \( p \), or are all equal if \( p \) is not given.

If \( x \) is a matrix with at least two rows and columns, it is taken as a two-dimensional contingency table: the entries of \( x \) must be non-negative integers. Otherwise, \( x \) and \( y \) must be vectors or factors of the same length; cases with missing values are removed, the objects are coerced to factors, and the contingency table is computed from these. Then Pearson’s chi-squared test is performed of the null hypothesis that the joint distribution of the cell counts in a 2-dimensional contingency table is the product of the row and column marginals.

If \( \text{simulate.p.value} \) is \( \text{FALSE} \), the p-value is computed from the asymptotic chi-squared distribution of the test statistic; continuity correction is only used in the 2-by-2 case (if \( \text{correct} \) is \( \text{TRUE} \), the default). Otherwise the p-value is computed for a Monte Carlo test (Hope, 1968) with \( B \) replicates.

In the contingency table case simulation is done by random sampling from the set of all contingency tables with given marginals, and works only if the marginals are strictly positive. Continuity correction is never used, and the statistic is quoted without it. Note that this is not the usual sampling situation assumed for the chi-squared test but rather that for Fisher’s exact test.

In the goodness-of-fit case simulation is done by random sampling from the discrete distribution specified by \( p \), each sample being of size \( n = \text{sum}(x) \). This simulation is done in \( R \) and may be slow.

Value

A list with class “htest” containing the following components:

- \( \text{statistic} \): the value the chi-squared test statistic.
- \( \text{parameter} \): the degrees of freedom of the approximate chi-squared distribution of the test statistic, \( N \) if the p-value is computed by Monte Carlo simulation.
- \( \text{p.value} \): the p-value for the test.
- \( \text{method} \): a character string indicating the type of test performed, and whether Monte Carlo simulation or continuity correction was used.
- \( \text{data.name} \): a character string giving the name(s) of the data.
- \( \text{observed} \): the observed counts.
- \( \text{expected} \): the expected counts under the null hypothesis.
- \( \text{residuals} \): the Pearson residuals, \( (\text{observed} - \text{expected}) / \sqrt{\text{expected}} \).
- \( \text{stdres} \): standardized residuals, \( (\text{observed} - \text{expected}) / \sqrt{V} \), where \( V \) is the residual cell variance (Agresti, 2007, section 2.4.5 for the case where \( x \) is a matrix, \( n * p * (1 - p) \) otherwise).

Source

The code for Monte Carlo simulation is a C translation of the Fortran algorithm of Patefield (1981).

References

**See Also**

For goodness-of-fit testing, notably of continuous distributions, `ks.test`.

**Examples**

```r
## From Agresti(2007) p.39
M <- as.table(rbind(c(762, 327, 468), c(484, 239, 477)))
dimnames(M) <- list(gender = c("F", "M"),
party = c("Democrat","Independent","Republican"))
(Xsq <- chisq.test(M))  # Prints test summary
Xsq$observed    # observed counts (same as M)
Xsq$expected    # expected counts under the null
Xsq$residuals   # Pearson residuals
Xsq$stdres      # standardized residuals

## Effect of simulating p-values
x <- matrix(c(12, 5, 7, 7), ncol = 2)
chisq.test(x)$p.value # 0.4233
chisq.test(x, simulate.p.value = TRUE, B = 10000)$p.value
# around 0.29!

## Testing for population probabilities
## Case A. Tabulated data
x <- c(A = 20, B = 15, C = 25)
chisq.test(x)
chisq.test(as.table(x)) # the same
x <- c(89,37,30,28,2)
p <- c(40,20,20,15,5)
try(
  chisq.test(x, p = p) # gives an error
)
chisq.test(x, p = p, rescale.p = TRUE)
# works
p <- c(0.40,0.20,0.20,0.19,0.01)
# Expected count in category 5
# is 1.86 < 5 ==> chi square approx.
chisq.test(x, p = p)
# maybe doubtful, but is ok!
chisq.test(x, p = p, simulate.p.value = TRUE)

## Case B. Raw data
x <- trunc(5 * runif(100))
chisq.test(table(x)) # NOT 'chisq.test(x)'!
```

---

**Chisquare**  
*The (non-central) Chi-Squared Distribution*
Description

Density, distribution function, quantile function and random generation for the chi-squared ($\chi^2$) distribution with $df$ degrees of freedom and optional non-centrality parameter $ncp$.

Usage

dchisq(x, df, ncp = 0, log = FALSE)
pchisq(q, df, ncp = 0, lower.tail = TRUE, log.p = FALSE)
qchisq(p, df, ncp = 0, lower.tail = TRUE, log.p = FALSE)
rchisq(n, df, ncp = 0)

Arguments

x, q  vector of quantiles.
p  vector of probabilities.
n  number of observations. If length(n) > 1, the length is taken to be the number
  required.
df  degrees of freedom (non-negative, but can be non-integer).
ncp  non-centrality parameter (non-negative).
log, log.p  logical; if TRUE, probabilities p are given as log(p).
lower.tail  logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The chi-squared distribution with $df = n \geq 0$ degrees of freedom has density

$$f_n(x) = \frac{1}{2^{n/2} \Gamma(n/2)} x^{n/2-1} e^{-x/2}$$

for $x > 0$. The mean and variance are $n$ and $2n$.

The non-central chi-squared distribution with $df = n$ degrees of freedom and non-centrality parameter $ncp = \lambda$ has density

$$f(x) = e^{-\lambda/2} \sum_{r=0}^{\infty} \frac{(\lambda/2)^r}{r!} f_{n+2r}(x)$$

for $x \geq 0$. For integer $n$, this is the distribution of the sum of squares of $n$ normals each with variance one, $\lambda$ being the sum of squares of the normal means; further, $E(X) = n + \lambda$, $Var(X) = 2(n + 2 \cdot \lambda)$, and $E((X - E(X))^3) = 8(n + 3 \cdot \lambda)$.

Note that the degrees of freedom $df = n$, can be non-integer, and also $n = 0$ which is relevant for non-centrality $\lambda > 0$, see Johnson et al (1995, chapter 29).

Note that $ncp$ values larger than about 1e5 may give inaccurate results with many warnings for pchisq and qchisq.

Value

dchisq gives the density, pchisq gives the distribution function, qchisq gives the quantile function, and rchisq generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rchisq, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.
Note
Supplying \( ncp = 0 \) uses the algorithm for the non-central distribution, which is not the same algorithm used if \( ncp \) is omitted. This is to give consistent behaviour in extreme cases with values of \( ncp \) very near zero.

The code for non-zero \( ncp \) is principally intended to be used for moderate values of \( ncp \): it will not be highly accurate, especially in the tails, for large values.

Source
The central cases are computed via the gamma distribution.
The non-central \( \text{dchisq} \) and \( \text{rchisq} \) are computed as a Poisson mixture central of chi-squares (Johnson et al., 1995, p.436).
The non-central \( \text{pchisq} \) is for \( ncp < 80 \) computed from the Poisson mixture of central chi-squares and for larger \( ncp \) via a C translation of
which computes the lower tail only (so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant).
The non-central \( \text{qchisq} \) is based on inversion of \( \text{pchisq} \).

References

See Also
\text{Distributions} for other standard distributions.
A central chi-squared distribution with \( n \) degrees of freedom is the same as a Gamma distribution with shape \( \alpha = n/2 \) and scale \( \sigma = 2 \). Hence, see \text{dgamma} for the Gamma distribution.

Examples
```r
require(graphics)
dchisq(1, df = 1:3)
pchisq(1, df = 3)
pchisq(1, df = 3, ncp = 0:4)  # includes the above

x <- 1:10
## Chi-squared\((df = 2)\) is a special exponential distribution
dall.equal(dchisq(x, df = 2), dexp(x, 1/2))
dall.equal(pchisq(x, df = 2), pexp(x, 1/2))

## non-central RNG -- df = 0 with ncp > 0: \( \hat{Z} \) has point mass at 0!
Z0 <- rchisq(100, df = 0, ncp = 2.)
graphics::stem(Z0)

## visual testing
## do P-P plots for 1000 points at various degrees of freedom
```
Classical (Metric) Multidimensional Scaling

Description

Classical multidimensional scaling of a data matrix. Also known as principal coordinates analysis (Gower, 1966).

Usage

```r
cmdscale(d, k = 2, eig = FALSE, add = FALSE, x.ret = FALSE)
```

Arguments

- `d`: a distance structure such as that returned by `dist` or a full symmetric matrix containing the dissimilarities.
- `k`: the maximum dimension of the space which the data are to be represented in; must be in \{1, 2, \ldots, n \}.
- `eig`: indicates whether eigenvalues should be returned.
- `add`: logical indicating if an additive constant \( c^* \) should be computed, and added to the non-diagonal dissimilarities such that the modified dissimilarities are Euclidean.
- `x.ret`: indicates whether the doubly centred symmetric distance matrix should be returned.

Details

Multidimensional scaling takes a set of dissimilarities and returns a set of points such that the distances between the points are approximately equal to the dissimilarities. (It is a major part of what ecologists call ‘ordination’.)

```r
L <- 1.2; n <- 1000; pp <- ppoints(n)
op <- par(mfrow = c(3,3), mar = c(3,3,1,1)+.1, mgp = c(1.5,.6,0), oma = c(0,0,3,0))
for(df in 2^4*runif(9)) {
  plot(pp, sort(pchisq(rr <- rchisq(n, df = df, ncp = L)), df = df, ncp = L)),
   ylab = "pchisq(rchisq(.),)", pch = "."
  mtext(paste("df = ", formatC(df, digits = 4)), line = -2, adj = 0.05)
  abline(0, 1, col = 2)
}

mtext(expression("P-P plots : Noncentral "* 
   chi^2 *(n=1000, df=K, ncp= 1.2)"),
   cex = 1.5, font = 2, outer = TRUE)
par(op)
```
A set of Euclidean distances on \( n \) points can be represented exactly in at most \( n - 1 \) dimensions. `cmdscale` follows the analysis of Mardia (1978), and returns the best-fitting \( k \)-dimensional representation, where \( k \) may be less than the argument \( k \).

The representation is only determined up to location (`cmdscale` takes the column means of the configuration to be at the origin), rotations and reflections. The configuration returned is given in principal-component axes, so the reflection chosen may differ between \( \mathbb{R} \) platforms (see `prcomp`).

When `add = TRUE`, a minimal additive constant \( c^* \) is computed such that the the dissimilarities \( d_{ij} + c^* \) are Euclidean and hence can be represented in \( n - 1 \) dimensions. Whereas \( S \) (Becker et al, 1988) computes this constant using an approximation suggested by Torgerson, \( \mathbb{R} \) uses the analytical solution of Cailliez (1983), see also Cox and Cox (2001). Note that because of numerical errors the computed eigenvalues need not all be non-negative, and even theoretically the representation could be in fewer than \( n - 1 \) dimensions.

**Value**

If `eig = FALSE, add = FALSE` and `x.ret = FALSE` (default), a matrix with \( k \) columns whose rows give the coordinates of the points chosen to represent the dissimilarities.

Otherwise, a list containing the following components.

- `points` a matrix with up to \( k \) columns whose rows give the coordinates of the points chosen to represent the dissimilarities.
- `eig` the \( n \) eigenvalues computed during the scaling process if `eig` is true. **NB:** versions of \( \mathbb{R} \) before 2.12.1 returned only \( k \) but were documented to return \( n - 1 \).
- `x` the doubly centered distance matrix if `x.ret` is true.
- `ac` the additive constant \( c^*, 0 \) if `add = FALSE`.
- `gof` a numeric vector of length 2, equal to say \((g_1, g_2)\), where \( g_i = (\sum_{j=1}^{k} \lambda_j)/(\sum_{j=1}^{n} T_i(\lambda_j)) \), where \( \lambda_j \) are the eigenvalues (sorted in decreasing order), \( T_1(v) = |v| \), and \( T_2(v) = \max(v, 0) \).

dist.
isoMDS and sammon in package MASS provide alternative methods of multidimensional scaling.

Examples

require(graphics)

loc <- cmdscale(euordist)
x <- loc[, 1]
y <- -loc[, 2] # reflect so North is at the top
## note asp = 1, to ensure Euclidean distances are represented correctly
plot(x, y, type = "n", xlab = "", ylab = "", asp = 1, axes = FALSE,
     main = "cmdscale(euordist)")
text(x, y, rownames(loc), cex = 0.6)

coef

Extract Model Coefficients

Description

coeff is a generic function which extracts model coefficients from objects returned by modeling functions. coefficients is an alias for it.

Usage

coeff(object, ...)
coefficients(object, ...)

Arguments

object an object for which the extraction of model coefficients is meaningful.
...
other arguments.

Details

All object classes which are returned by model fitting functions should provide a coef method or use the default one. (Note that the method is for coef and not coefficients.)

Class "aov" has a coef method that does not report aliased coefficients (see alias).

Value

Coefficients extracted from the model object object.

For standard model fitting classes this will be a named numeric vector.

References

See Also

fitted.values and residuals for related methods; glm, lm for model fitting.
**complete.cases**

**Find Complete Cases**

**Examples**

```r
x <- 1:5; coef(lm(c(1:3, 7, 6) ~ x))
```

**Description**

Return a logical vector indicating which cases are complete, i.e., have no missing values.

**Usage**

```r
complete.cases(...)
```

**Arguments**

... a sequence of vectors, matrices and data frames.

**Value**

A logical vector specifying which observations/rows have no missing values across the entire sequence.

**See Also**

`is.na`, `na.omit`, `na.fail`.

**Examples**

```r
x <- airquality[, -1] # x is a regression design matrix
y <- airquality[, 1] # y is the corresponding response

stopifnot(complete.cases(y) != is.na(y))
ok <- complete.cases(x, y)
sum(!ok) # how many are not "ok" ?
x <- x[ok,]
y <- y[ok]
```

---

**confint**

**Confidence Intervals for Model Parameters**

**Description**

Computes confidence intervals for one or more parameters in a fitted model. There is a default and a method for objects inheriting from class "lm".

**Usage**

```r
confint(object, parm, level = 0.95, ...)
```
Arguments

object a fitted model object.
parm a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
level the confidence level required.
... additional argument(s) for methods.

Details

confint is a generic function. The default method assumes asymptotic normality, and needs suitable coef and vcov methods to be available. The default method can be called directly for comparison with other methods.

For objects of class "lm" the direct formulae based on t values are used.
There are stub methods for classes "glm" and "nls" which invoke those in package MASS which are based on profile likelihoods.

Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1-level)/2 and 1 - (1-level)/2 in % (by default 2.5% and 97.5%).

See Also

confint.glm and confint.nls in package MASS.

Examples

fit <- lm(mpg ~ disp + hp + wt + am, data = mtcars)
confint(fit)
confint(fit, "wt")

## from example(glm)
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3, 1, 9); treatment <- gl(3, 3)
glm.D93 <- glm(counts ~ outcome + treatment, family = poisson())
confint(glm.D93) # needs MASS to be present on the system
confint.default(glm.D93) # based on asymptotic normality

constrOptim

**Linearly Constrained Optimization**

Description

Minimise a function subject to linear inequality constraints using an adaptive barrier algorithm.

Usage

constrOptim(theta, f, grad, ui, ci, mu = 1e-04, control = list(),
method = if(is.null(grad)) "Nelder-Mead" else "BFGS",
outer.iterations = 100, outer.eps = 1e-05, ...,
hessian = FALSE)
**constrOptim**

**Arguments**

- **theta**: numeric (vector) starting value (of length p): must be in the feasible region.
- **f**: function to minimise (see below).
- **grad**: gradient of f (a function as well), or NULL (see below).
- **ui**: constraint matrix (k x p), see below.
- **ci**: constraint vector of length k (see below).
- **mu**: (Small) tuning parameter.
- **control, method, hessian**: passed to **optim**.
- **outer.iterations**: iterations of the barrier algorithm.
- **outer.eps**: non-negative number; the relative convergence tolerance of the barrier algorithm.
- **...**: Other named arguments to be passed to f and grad: needs to be passed through **optim** so should not match its argument names.

**Details**

The feasible region is defined by $\mathbf{ui} \mathbf{E} \mathbf{J} \mathbf{E} \theta - $ $\mathbf{ci} >= 0$. The starting value must be in the interior of the feasible region, but the minimum may be on the boundary.

A logarithmic barrier is added to enforce the constraints and then **optim** is called. The barrier function is chosen so that the objective function should decrease at each outer iteration. Minima in the interior of the feasible region are typically found quite quickly, but a substantial number of outer iterations may be needed for a minimum on the boundary.

The tuning parameter $\mu$ multiplies the barrier term. Its precise value is often relatively unimportant. As $\mu$ increases the augmented objective function becomes closer to the original objective function but also less smooth near the boundary of the feasible region.

Any **optim** method that permits infinite values for the objective function may be used (currently all but "L-BFGS-B").

The objective function f takes as first argument the vector of parameters over which minimisation is to take place. It should return a scalar result. Optional arguments ... will be passed to **optim** and then (if not used by **optim**) to f. As with **optim**, the default is to minimise, but maximisation can be performed by setting control$\$fnscale to a negative value.

The gradient function grad must be supplied except with method = "Nelder-Mead". It should take arguments matching those of f and return a vector containing the gradient.

**Value**

As for **optim**, but with two extra components: **barrier.value** giving the value of the barrier function at the optimum and **outer.iterations** gives the number of outer iterations (calls to **optim**).

The counts component contains the sum of all **optim()$counts**.

### Examples

```r
## from optim
fr <- function(x) {   ## Rosenbrock Banana function
  x1 <- x[1]
  x2 <- x[2]
  100 * (x2 - x1 * x1)^2 + (1 - x1)^2
}
grr <- function(x) {  ## Gradient of 'fr'
  x1 <- x[1]
  x2 <- x[2]
  c(-400 * x1 * (x2 - x1 * x1) - 2 * (1 - x1),
     200 * (x2 - x1 * x1))
}

optim(c(-1.2,1), fr, grr)
#Box-constraint, optimum on the boundary
constrOptim(c(-1.2,0.9), fr, grr, ui = rbind(c(-1,0), c(0,-1)), ci = c(-1,-1))
  # x <= 0.9, y - x > 0.1
constrOptim(c(.5,0), fr, grr, ui = rbind(c(-1,0), c(1,-1)), ci = c(-0.9,0,1))

## Solves linear and quadratic programming problems
## but needs a feasible starting value
#
# from example(solve.QP) in 'quadprog'
# no derivative
fQP <- function(b) (-sum(c(0,5,0)*b)+0.5*sum(b*b))
Amat <- matrix(c(-4,-3,0,2,1,0,0,-2,1), 3, 3)
bvec <- c(-8, 2, 0)
constrOptim(c(2,-1,-1), fQP, NULL, ui = t(Amat), ci = bvec)
# derivative
gQP <- function(b) (-c(0, 5, 0) + b)
constrOptim(c(2,-1,-1), fQP, gQP, ui = t(Amat), ci = bvec)

## Now with maximisation instead of minimisation
hQP <- function(b) (sum(c(0,5,0)*b)-0.5*sum(b*b))
constrOptim(c(2,-1,-1), hQP, NULL, ui = t(Amat), ci = bvec,
             control = list(fnscale = -1))
```

### Description

Return a matrix of contrasts.

### Usage

- `contr.helmert(n, contrasts = TRUE, sparse = FALSE)`
- `contr.poly(n, scores = 1:n, contrasts = TRUE, sparse = FALSE)`
- `contr.sum(n, contrasts = TRUE, sparse = FALSE)`
- `contr.treatment(n, base = 1, contrasts = TRUE, sparse = FALSE)`
- `contr.SAS(n, contrasts = TRUE, sparse = FALSE)`
### Arguments

- `n`: a vector of levels for a factor, or the number of levels.
- `contrasts`: a logical indicating whether contrasts should be computed.
- `sparse`: logical indicating if the result should be sparse (of class `dgCMatrix`), using package `Matrix`.
- `scores`: the set of values over which orthogonal polynomials are to be computed.
- `base`: an integer specifying which group is considered the baseline group. Ignored if `contrasts` is `FALSE`.

### Details

These functions are used for creating contrast matrices for use in fitting analysis of variance and regression models. The columns of the resulting matrices contain contrasts which can be used for coding a factor with `n` levels. The returned value contains the computed contrasts. If the argument `contrasts` is `FALSE` a square indicator matrix (the dummy coding) is returned except for `contr.poly` (which includes the 0-degree, i.e., constant, polynomial when `contrasts = FALSE`).

- `contr.helmert` returns Helmert contrasts, which contrast the second level with the first, the third with the average of the first two, and so on. `contr.poly` returns contrasts based on orthogonal polynomials. `contr.sum` uses 'sum to zero contrasts'.
- `contr.treatment` contrasts each level with the baseline level (specified by `base`): the baseline level is omitted. Note that this does not produce 'contrasts' as defined in the standard theory for linear models as they are not orthogonal to the intercept.
- `contr.SAS` is a wrapper for `contr.treatment` that sets the base level to be the last level of the factor. The coefficients produced when using these contrasts should be equivalent to those produced by many (but not all) SAS procedures.

For consistency, `sparse` is an argument to all these contrast functions, however `sparse = TRUE` for `contr.poly` is typically pointless and is rarely useful for `contr.helmert`.

### Value

A matrix with `n` rows and `k` columns, with `k=n-1` if `contrasts` is `TRUE` and `k=n` if `contrasts` is `FALSE`.

### References

### See Also

- `contrasts`, `C`, and `aov`, `glm`, `lm`.

### Examples

```r
(cH <- contr.helmert(4))
apply(cH, 2, sum) # column sums are 0
crossprod(cH) # diagonal -- columns are orthogonal
contr.helmert(4, contrasts = FALSE) # just the 4 x 4 identity matrix

(cT <- contr.treatment(5))
all(crossprod(cT) == diag(4)) # TRUE: even orthonormal
```
contrasts

(cT. <- contr.SAS(5))
all(crossprod(cT.) == diag(4)) # TRUE

zapsmall(cP <- contr.poly(3)) # Linear and Quadratic
zapsmall(crossprod(cP), digits = 15) # orthonormal up to fuzz

---

**Description**

Set and view the contrasts associated with a factor.

**Usage**

```r
contrasts(x, contrasts = TRUE, sparse = FALSE)
contrasts(x, how.many) <- value
```

**Arguments**

- `x` : a factor or a logical variable.
- `contrasts` : logical. See ‘Details’.
- `sparse` : logical indicating if the result should be sparse (of class `dgCMatrix`), using package `Matrix`.
- `how.many` : How many contrasts should be made. Defaults to one less than the number of levels of `x`. This need not be the same as the number of columns of `value`.
- `value` : either a numeric matrix (or a sparse or dense matrix of a class extending `dMatrix` from package `Matrix`) whose columns give coefficients for contrasts in the levels of `x`, or the (quoted) name of a function which computes such matrices.

**Details**

If contrasts are not set for a factor the default functions from `options("contrasts")` are used.

A logical vector `x` is converted into a two-level factor with levels `c(FALSE, TRUE)` (regardless of which levels occur in the variable).

The argument `contrasts` is ignored if `x` has a matrix `contrasts` attribute set. Otherwise if `contrasts = TRUE` it is passed to a contrasts function such as `contr.treatment` and if `contrasts = FALSE` an identity matrix is returned. Suitable functions have a first argument which is the character vector of levels, a named argument `contrasts` (always called with `contrasts = TRUE`) and optionally a logical argument `sparse`.

If `value` supplies more than `how.many` contrasts, the first `how.many` are used. If too few are supplied, a suitable contrast matrix is created by extending `value` after ensuring its columns are contrasts (orthogonal to the constant term) and not collinear.

**References**

convolve

Convolution of Sequences via FFT

Description

Use the Fast Fourier Transform to compute the several kinds of convolutions of two sequences.

Usage

```r
convolve(x, y, conj = TRUE, type = c("circular", "open", "filter"))
```

Arguments

- `x, y`: numeric sequences of the same length to be convolved.
- `conj`: logical; if TRUE, take the complex conjugate before back-transforming (default, and used for usual convolution).
- `type`: character; one of "circular", "open", "filter" (beginning of word is ok). For circular, the two sequences are treated as circular, i.e., periodic. For open and filter, the sequences are padded with 0s (from left and right) first; "filter" returns the middle sub-vector of "open", namely, the result of running a weighted mean of `x` with weights `y`.

Details

The Fast Fourier Transform, `fft`, is used for efficiency.

The input sequences `x` and `y` must have the same length if circular is true.

Note that the usual definition of convolution of two sequences `x` and `y` is given by `convolve(x, rev(y), type = "o")`. 

Examples

```r
utils::example(factor)
fff <- ffs[, drop = TRUE] # reduce to 5 levels.
contrasts(fff) # treatment contrasts by default
contrasts(C(fff, sum))
contrasts(fff, contrasts = FALSE) # the 5x5 identity matrix

contrasts(fff) <- contr.sum(5); contrasts(fff) # set sum contrasts
contrasts(fff, 2) <- contr.sum(5); contrasts(fff) # set 2 contrasts
# supply 2 contrasts, compute 2 more to make full set of 4.
contrasts(fff) <- contr.sum(5)[, 1:2]; contrasts(fff)

## using sparse contrasts: % useful, once model.matrix() works with these :
ffs <- ffs
contrasts(ffs) <- contr.sum(5, sparse = TRUE)[, 1:2]; contrasts(ffs)
stopifnot(all.equal(ffs, ffs))
contrasts(ffs) <- contr.sum(5, sparse = TRUE); contrasts(ffs)
```
Value

If \( r \leftarrow \text{convolve}(x, y, \text{type} = "\text{open}" ) \) and \( n \leftarrow \text{length}(x), m \leftarrow \text{length}(y) \), then

\[
r_k = \sum_i x_{k-m+i} y_i
\]

where the sum is over all valid indices \( i \), for \( k = 1, \ldots, n + m - 1 \).

If \( \text{type} = "\text{circular}" \), \( n = m \) is required, and the above is true for \( i, k = 1, \ldots, n \) when

\[
x_j \equiv x_{n+j} \text{ for } j < 1.
\]

References

\texttt{fft}, \texttt{nextn}, and particularly \texttt{filter} (from the \texttt{stats} package) which may be more appropriate.

Examples

```r
require(graphics)
x <- c(0,0,0,100,0,0,0)
y <- c(0,0,1,2,1,0,0)/4
zapsmall(\text{convolve}(x, y)) \# *NOT* what you first thought.
zapsmall(\text{convolve}(x, y[3:5], \text{type} = "f")) \# rather
x <- rnorm(50)
y <- rnorm(50)
# Circular convolution *has* this symmetry:
\text{all.equal}(\text{convolve}(x, y, \text{conj} = \text{FALSE}), \text{rev}(\text{convolve}(\text{rev}(y), x)))

n <- \text{length}(x <- -20:24)
y <- (x-10)^2/1000 + rnorm(x)/8
Han <- \text{function}(y) \# Hanning
\text{convolve}(y, c(1,2,1)/4, \text{type} = "filter")

\text{plot}(x, y, \text{main} = "Using convolve(.) for Hanning filters")
\text{lines}(x[-c(1, n)], Han(y), \text{col} = "red")
\text{lines}(x[-c(1:2, (n-1):n)], Han(Han(y)), \text{lwd} = 2, \text{col} = "dark blue")
```

---

cophenetic | *Cophenetic Distances for a Hierarchical Clustering*

Description

Computes the cophenetic distances for a hierarchical clustering.
Usage

cophenetic(x)
## Default S3 method:
cophenetic(x)
## S3 method for class 'dendrogram'
cophenetic(x)

Arguments

x an R object representing a hierarchical clustering. For the default method, an object of class "hclust" or with a method for as.hclust() such as "agnes" in package cluster.

Details

The cophenetic distance between two observations that have been clustered is defined to be the intergroup dissimilarity at which the two observations are first combined into a single cluster. Note that this distance has many ties and restrictions.

It can be argued that a dendrogram is an appropriate summary of some data if the correlation between the original distances and the cophenetic distances is high. Otherwise, it should simply be viewed as the description of the output of the clustering algorithm.

cophenetic is a generic function. Support for classes which represent hierarchical clusterings (total indexed hierarchies) can be added by providing an as.hclust() or, more directly, a cophenetic() method for such a class.

The method for objects of class "dendrogram" requires that all leaves of the dendrogram object have non-null labels.

Value

An object of class "dist".

Author(s)

Robert Gentleman

hc <- hclust(d1, "ave")
d2 <- cophenetic(hc)
cor(d1, d2) # 0.7659
Correlation, Variance and Covariance (Matrices)

Description

`var`, `cov` and `cor` compute the variance of `x` and the covariance or correlation of `x` and `y` if these are vectors. If `x` and `y` are matrices then the covariances (or correlations) between the columns of `x` and the columns of `y` are computed.

`cov2cor` scales a covariance matrix into the corresponding correlation matrix efficiently.

Usage

``` R
var(x, y = NULL, na.rm = FALSE, use)
cov(x, y = NULL, use = "everything", method = c("pearson", "kendall", "spearman"))
cor(x, y = NULL, use = "everything", method = c("pearson", "kendall", "spearman"))
cov2cor(V)
```

Arguments

- **x**: a numeric vector, matrix or data frame.
- **y**: NULL (default) or a vector, matrix or data frame with compatible dimensions to `x`. The default is equivalent to `y = x` (but more efficient).
- **na.rm**: logical. Should missing values be removed?
- **use**: an optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete", or "pairwise.complete.obs".
- **method**: a character string indicating which correlation coefficient (or covariance) is to be computed. One of "pearson" (default), "kendall", or "spearman", can be abbreviated.
- **V**: symmetric numeric matrix, usually positive definite such as a covariance matrix.
Details

For `cov` and `cor` one must either give a matrix or data frame for `x` or give both `x` and `y`.

The inputs must be numeric (as determined by `is.numeric`; logical values are also allowed for historical compatibility): the "kendall" and "spearman" methods make sense for ordered inputs but `xtfrm` can be used to find a suitable prior transformation to numbers.

`var` is just another interface to `cov`, where `na.rm` is used to determine the default for use when that is unspecified. If `na.rm` is `TRUE` then the complete observations (rows) are used (use = "na.or.complete") to compute the variance. Otherwise, by default use = "everything".

If use is "everything", `NA`s will propagate conceptually, i.e., a resulting value will be `NA` whenever one of its contributing observations is `NA`.

If use is "all.obs", then the presence of missing observations will produce an error. If use is "complete.obs" then missing values are handled by casewise deletion (and if there are no complete cases, that gives an error).

"na.or.complete" is the same unless there are no complete cases, that gives `NA`. Finally, if use has the value "pairwise.complete.obs" then the correlation or covariance between each pair of variables is computed using all complete pairs of observations on those variables. This can result in covariance or correlation matrices which are not positive semi-definite, as well as `NA` entries if there are no complete pairs for that pair of variables. For `cov` and `var`, "pairwise.complete.obs" only works with the "pearson" method. Note that (the equivalent of) `var(double(0), use = *)` gives `NA` for use = "everything" and "na.or.complete", and gives an error in the other cases.

The denominator $n - 1$ is used which gives an unbiased estimator of the (co)variance for i.i.d. observations. These functions return `NA` when there is only one observation (whereas S-PLUS has been returning `NaN`), and fail if `x` has length zero.

For `cor()`, if method is "kendall" or "spearman", Kendall’s $\tau$ or Spearman’s $\rho$ statistic is used to estimate a rank-based measure of association. These are more robust and have been recommended if the data do not necessarily come from a bivariate normal distribution.

For `cov()`, a non-Pearson method is unusual but available for the sake of completeness. Note that "spearman" basically computes `cor(R(x), R(y))` (or `cov(., .)`) where `R(u) := rank(u, na.last = "keep")`. In the case of missing values, the ranks are calculated depending on the value of use, either based on complete observations, or based on pairwise completeness with reranking for each pair.

Scaling a covariance matrix into a correlation one can be achieved in many ways, mathematically most appealing by multiplication with a diagonal matrix from left and right, or more efficiently by using `sweep(., FUN = "/")` twice. The `cov2cor` function is even a bit more efficient, and provided mostly for didactical reasons.

Value

For $r \text{ <- } \text{cor}(\ast, \text{use = "all.obs"})$, it is now guaranteed that $\text{all}(r <= 1)$.

Note

Some people have noted that the code for Kendall’s tau is slow for very large datasets (many more than 1000 cases). It rarely makes sense to do such a computation, but see function `cor.fk` in package `pcaPP`.

symnum(Rc <- cor(swM, method = "kendall", use = "complete"))
symnum(Rp <- cor(swM, method = "kendall", use = "pairwise"))
```
cor.test

Test for Association/Correlation Between Paired Samples

Description

Test for association between paired samples, using one of Pearson’s product moment correlation coefficient, Kendall’s $\tau$ or Spearman’s $\rho$.

Usage

cor.test(x, ...)  

## Default S3 method:  
cor.test(x, y,  
  alternative = c("two.sided", "less", "greater"),  
  method = c("pearson", "kendall", "spearman"),  
  exact = NULL, conf.level = 0.95, continuity = FALSE, ...)  

## S3 method for class 'formula'  
cor.test(formula, data, subset, na.action, ...)

Arguments

- **x, y**: numeric vectors of data values. x and y must have the same length.
- **alternative**: indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. "greater" corresponds to positive association, "less" to negative association.
- **method**: a character string indicating which correlation coefficient is to be used for the test. One of "pearson", "kendall", or "spearman", can be abbreviated.
- **exact**: a logical indicating whether an exact p-value should be computed. Used for Kendall’s $\tau$ and Spearman’s $\rho$. See ‘Details’ for the meaning of NULL (the default).
- **conf.level**: confidence level for the returned confidence interval. Currently only used for the Pearson product moment correlation coefficient if there are at least 4 complete pairs of observations.
- **continuity**: logical: if true, a continuity correction is used for Kendall’s $\tau$ and Spearman’s $\rho$ when not computed exactly.
- **formula**: a formula of the form ~ u + v, where each of u and v are numeric variables giving the data values for one sample. The samples must be of the same length.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").

... further arguments to be passed to or from methods.

**Details**

The three methods each estimate the association between paired samples and compute a test of the value being zero. They use different measures of association, all in the range \([-1, 1]\] with 0 indicating no association. These are sometimes referred to as tests of no correlation, but that term is often confined to the default method.

If method is "pearson", the test statistic is based on Pearson’s product moment correlation coefficient \(\text{cor}(x, y)\) and follows a \(t\) distribution with \(\text{length}(x) - 2\) degrees of freedom if the samples follow independent normal distributions. If there are at least 4 complete pairs of observation, an asymptotic confidence interval is given based on Fisher’s Z transform.

If method is "kendall" or "spearman", Kendall’s \(\tau\) or Spearman’s \(\rho\) statistic is used to estimate a rank-based measure of association. These tests may be used if the data do not necessarily come from a bivariate normal distribution.

For Kendall’s test, by default (if exact is NULL), an exact p-value is computed if there are less than 50 paired samples containing finite values and there are no ties. Otherwise, the test statistic is the estimate scaled to zero mean and unit variance, and is approximately normally distributed.

For Spearman’s test, p-values are computed using algorithm AS 89 for \(n < 1290\) and exact = TRUE, otherwise via the asymptotic \(t\) approximation. Note that these are ‘exact’ for \(n < 10\), and use an Edgeworth series approximation for larger sample sizes (the cutoff has been changed from the original paper).

**Value**

A list with class "htest" containing the following components:

- statistic the value of the test statistic.
- parameter the degrees of freedom of the test statistic in the case that it follows a \(t\) distribution.
- p.value the p-value of the test.
- estimate the estimated measure of association, with name "cor", "tau", or "rho" corresponding to the method employed.
- null.value the value of the association measure under the null hypothesis, always 0.
- alternative a character string describing the alternative hypothesis.
- method a character string indicating how the association was measured.
- data.name a character string giving the names of the data.
- conf.int a confidence interval for the measure of association. Currently only given for Pearson’s product moment correlation coefficient in case of at least 4 complete pairs of observations.

Kendall in package Kendall.

pkendall and pspearman in package SuppDists, spearman.test in package pspearman, which supply different (and often more accurate) approximations.

Examples

```r
## Assessment of tuna quality. We compare the Hunter L measure of
## lightness to the averages of consumer panel scores (recoded as
## integer values from 1 to 6 and averaged over 80 such values) in
## 9 lots of canned tuna.

x <- c(44.4, 45.9, 41.9, 53.3, 44.7, 44.1, 50.7, 45.2, 60.1)
y <- c(2.6, 3.1, 2.5, 5.0, 3.6, 4.0, 5.2, 2.8, 3.0)

## The alternative hypothesis of interest is that the
## Hunter L value is positively associated with the panel score.
cor.test(x, y, method = "kendall", alternative = "greater")
## => p=0.05972
cor.test(x, y, method = "kendall", alternative = "greater",
        exact = FALSE) # using large sample approximation
## => p=0.04765

## Compare this to
cor.test(x, y, method = "spearman", alternative = "g")
cor.test(x, y, alternative = "g")

## Formula interface.
require(graphics)
pairs(USJudgeRatings)
cor.test(~ CONT + INTG, data = USJudgeRatings)
```

Description

Returns a list containing estimates of the weighted covariance matrix and the mean of the data, and optionally of the (weighted) correlation matrix.
cov.wt

Usage

cov.wt(x, wt = rep(1/nrow(x), nrow(x)), cor = FALSE, center = TRUE,
method = c("unbiased", "ML"))

Arguments

x a matrix or data frame. As usual, rows are observations and columns are variables.
wt a non-negative and non-zero vector of weights for each observation. Its length must equal the number of rows of x.
cor a logical indicating whether the estimated correlation weighted matrix will be returned as well.
center either a logical or a numeric vector specifying the centers to be used when computing covariances. If TRUE, the (weighted) mean of each variable is used, if FALSE, zero is used. If center is numeric, its length must equal the number of columns of x.
method string specifying how the result is scaled, see ‘Details’ below.

Details

By default, method = "unbiased". The covariance matrix is divided by one minus the sum of squares of the weights, so if the weights are the default (1/n) the conventional unbiased estimate of the covariance matrix with divisor (n − 1) is obtained. This differs from the behaviour in S-PLUS which corresponds to method = "ML" and does not divide.

Value

A list containing the following named components:

cov the estimated (weighted) covariance matrix
center an estimate for the center (mean) of the data.
n.obs the number of observations (rows) in x.
wt the weights used in the estimation. Only returned if given as an argument.
cor the estimated correlation matrix. Only returned if cor is TRUE.

Examples

(xy <- cbind(x = 1:10, y = c(1:3, 8:5, 8:10)))
w1 <- c(0,0,0,1,1,1,1,1,0,0)
cov.wt(xy, wt = w1) # i.e. method = "unbiased"
cov.wt(xy, wt = w1, method = "ML", cor = TRUE)
Plot Cumulative Periodogram

Description

Plots a cumulative periodogram.

Usage

```r
cpgram(ts, taper = 0.1,
       main = paste("Series: ", deparse(substitute(ts)),
       ci.col = "blue")
```  

Arguments

- `ts`: a univariate time series
- `taper`: proportion tapered in forming the periodogram
- `main`: main title
- `ci.col`: colour for confidence band.

Value

None.

Side Effects

Plots the cumulative periodogram in a square plot.

Note

From package MASS.

Examples

```r
require(graphics)
par(pty = "s", mfrow = c(1,2))
cpgram(lh)
lh.ar <- ar(lh, order.max = 9)
cpgram(lh.ar$resid, main = "AR(3) fit to lh")

cpgram(1deaths)
```
cutree

Cut a Tree into Groups of Data

Description
Cut a tree, e.g., as resulting from `hclust`, into several groups either by specifying the desired number(s) of groups or the cut height(s).

Usage
```r
cutree(tree, k = NULL, h = NULL)
```

Arguments
- `tree`: a tree as produced by `hclust`. `cutree()` only expects a list with components `merge`, `height`, and `labels`, of appropriate content each.
- `k`: an integer scalar or vector with the desired number of groups
- `h`: numeric scalar or vector with heights where the tree should be cut. At least one of `k` or `h` must be specified, `k` overrides `h` if both are given.

Details
Cutting trees at a given height is only possible for ultrametric trees (with monotone clustering heights).

Value
cutree returns a vector with group memberships if `k` or `h` are scalar, otherwise a matrix with group memberships is returned where each column corresponds to the elements of `k` or `h`, respectively (which are also used as column names).

References

See Also
`hclust`, `dendrogram` for cutting trees themselves.

Examples
```r
hc <- hclust(dist(USArrests))
cutree(hc, k = 1:5) #k = 1 is trivial
cutree(hc, h = 250)

## Compare the 2 and 4 grouping:
g24 <- cutree(hc, k = c(2,4))
table(grp2 = g24[,"2"], grp4 = g24[,"4"])```
**decompose**

*Classical Seasonal Decomposition by Moving Averages*

**Description**

Decompose a time series into seasonal, trend and irregular components using moving averages. Deals with additive or multiplicative seasonal component.

**Usage**

```r
decompose(x, type = c("additive", "multiplicative"), filter = NULL)
```

**Arguments**

- `x` A time series.
- `type` The type of seasonal component. Can be abbreviated.
- `filter` A vector of filter coefficients in reverse time order (as for AR or MA coefficients), used for filtering out the seasonal component. If `NULL`, a moving average with symmetric window is performed.

**Details**

The additive model used is:

\[ Y_t = T_t + S_t + e_t \]

The multiplicative model used is:

\[ Y_t = T_t S_t e_t \]

The function first determines the trend component using a moving average (if `filter` is `NULL`, a symmetric window with equal weights is used), and removes it from the time series. Then, the seasonal figure is computed by averaging, for each time unit, over all periods. The seasonal figure is then centered. Finally, the error component is determined by removing trend and seasonal figure (recycled as needed) from the original time series.

This only works well if `x` covers an integer number of complete periods.

**Value**

An object of class "decomposed.ts" with following components:

- `x` The original series. (Only since R 2.14.0.)
- `seasonal` The seasonal component (i.e., the repeated seasonal figure).
- `figure` The estimated seasonal figure only.
- `trend` The trend component.
- `random` The remainder part.
- `type` The value of `type`.

**Note**

The function `stl` provides a much more sophisticated decomposition.

```r
require(graphics)

m <- decompose(co2)
m$figure
plot(m)

## example taken from Kendall/Stuart
x <- c(-50, 175, 149, 214, 247, 237, 225, 329, 729, 809,
      530, 489, 540, 457, 195, 176, 337, 239, 128, 102, 232, 429, 3,
      98, 43, -141, -77, -13, 125, 301, -45, 184)
x <- ts(x, start = c(1951, 1), end = c(1958, 4), frequency = 4)
m <- decompose(x)
## seasonal figure: 6.25, 8.62, -8.84, -6.03
round(decompose(x)$figure / 10, 2)
```

---

deleteresponse  
Modify Terms Objects

Description

delete.response returns a terms object for the same model but with no response variable.
drop.terms removes variables from the right-hand side of the model. There is also a "[.terms" method to perform the same function (with keep.response = TRUE).
reformulate creates a formula from a character vector.

Usage

delete.response(termobj)

reformulate(termlabels, response = NULL, intercept = TRUE)
drop.terms(termobj, dropx = NULL, keep.response = FALSE)
Arguments

- `termobj`: A terms object
- `term.labels`: character vector giving the right-hand side of a model formula. Cannot be zero-length.
- `response`: character string, symbol or call giving the left-hand side of a model formula, or `NULL`.
- `intercept`: logical: should the formula have an intercept?
- `drop.x`: vector of positions of variables to drop from the right-hand side of the model.
- `keep.response`: Keep the response in the resulting object?

Value

delete.response and drop.terms return a terms object.
reformulate returns a formula.

See Also

- `terms`

Examples

```r
ff <- y ~ z + x + w
tt <- terms(ff)
tt
delete.response(tt)
drop.terms(tt, 2:3, keep.response = TRUE)
tt[[-1]]
tt[2:3]
reformulate(attr(tt, "term.labels"))

## keep LHS
reformulate("x*w", ff[2])
FS <- surv(ft, case) ~ a + b
reformulate(c("a", "b*f"), FS[[2]])

## using non-syntactic names:
reformulate(c("P/E", "% Growth"), response = as.name("+-"))

stopifnot(identical(~ var, reformulate("var")),
identical(~ a + b + c, reformulate(letters[1:3])),
identical( y ~ a + b, reformulate(letters[1:2], "y"))
```
Usage

dendrapply(X, FUN, ...)

Arguments

X an object of class "dendrogram".
FUN an R function to be applied to each dendrogram node, typically working on its
attributes alone, returning an altered version of the same node.
... potential further arguments passed to FUN.

Value

Usually a dendrogram of the same (graph) structure as X. For that, the function must be conceptually
of the form FUN <- function(X) { attributes(X) <- ......; X }, i.e., returning the node
with some attributes added or changed.

Note

this is still somewhat experimental, and suggestions for enhancements (or nice examples of usage)
are very welcome.

### Description

Class "dendrogram" provides general functions for handling tree-like structures. It is intended as a replacement for similar functions in hierarchical clustering and classification/regression trees, such that all of these can use the same engine for plotting or cutting trees.

### Usage

- `as.dendrogram(object, ...)`  
  ## S3 method for class 'hclust'
  `as.dendrogram(object, hang = -1, check = TRUE, ...)`  
  ## S3 method for class 'dendrogram'
  `as.hclust(x, ...)`  
  ## S3 method for class 'dendrogram'
  `plot(x, type = c("rectangle", "triangle"),
        center = FALSE,
        edge.root = is.leaf(x) || !is.null(attr(x,"edgetext")),
        nodePar = NULL, edgePar = list(),
        leaflab = c("perpendicular", "textlike", "none"),
        dLeaf = NULL, xlab = "", ylab = "", xaxt = "n", yaxt = "s",
        horiz = FALSE, frame.plot = FALSE, xlim, ylim, ...)`  
  ## S3 method for class 'dendrogram'
  `cut(x, h, ...)`  
  ## S3 method for class 'dendrogram'
  `merge(x, y, ..., height, adjust = c("auto", "add.max", "none"))`  
  ## S3 method for class 'dendrogram'
  `nobs(object, ...)`  
  ## S3 method for class 'dendrogram'
  `print(x, digits, ...)`  
  ## S3 method for class 'dendrogram'
  `rev(x)`  
  ## S3 method for class 'dendrogram'
  `str(object, max.level = NA, digits.d = 3,`
Arguments

- **object**: any R object that can be made into one of class "dendrogram".
- **x, y**: object(s) of class "dendrogram".
- **hang**: numeric scalar indicating how the height of leaves should be computed from the heights of their parents; see `plot.hclust`.
- **check**: logical indicating if object should be checked for validity. This check is not necessary when x is known to be valid such as when it is the direct result of `hclust()`. The default is check=TRUE, e.g. for protecting against memory explosion with invalid inputs.
- **type**: type of plot.
- **center**: logical; if TRUE, nodes are plotted centered with respect to the leaves in the branch. Otherwise (default), plot them in the middle of all direct child nodes.
- **edge.root**: logical; if true, draw an edge to the root node.
- **nodePar**: a list of plotting parameters to use for the nodes (see `points`) or NULL by default which does not draw symbols at the nodes. The list may contain components named `pch`, `cex`, `col`, `xpd`, and/or `bg` each of which can have length two for specifying separate attributes for inner nodes and leaves. Note that the default of `pch` is 1:2, so you may want to use `pch = NA` if you specify `nodePar`.
- **edgePar**: a list of plotting parameters to use for the edge segments and labels (if there’s an edgetext). The list may contain components named `col`, `lty` and `lwd` (for the segments), `p.col`, `p.lwd`, and `p.lty` (for the polygon around the text) and `t.col` for the text color. As with `nodePar`, each can have length two for differentiating leaves and inner nodes.
- **leaflab**: a string specifying how leaves are labeled. The default "perpendicular" write text vertically (by default).
- **textlike** writes text horizontally (in a rectangle), and "none" suppresses leaf labels.
- **dLeaf**: a number specifying the distance in user coordinates between the tip of a leaf and its label. If NULL as per default, 3/4 of a letter width or height is used.
- **horiz**: logical indicating if the dendrogram should be drawn horizontally or not.
- **frame.plot**: logical indicating if a box around the plot should be drawn, see `plot.default`.
- **height**: height at which the tree is cut.

**Additional Arguments**

- **adjust**: a string determining if the leaf values should be adjusted. The default, "auto", checks if the (first) two dendrograms both start at 1; if they do, code "add.max" is chosen, which adds the maximum of the previous dendrogram leaf values to each leaf of the "next" dendrogram. Specifying adjust to another value skips the check and hence is a tad more efficient.
The dendrogram is directly represented as a nested list where each component corresponds to a branch of the tree. Hence, the first branch of tree \( z \) is \( z[[1]] \), the second branch of the corresponding subtree is \( z[[1]][[2]] \), or shorter \( z[c(1,2)] \), etc.. Each node of the tree carries some information needed for efficient plotting or cutting as attributes, of which only \texttt{members}, \texttt{height} and \texttt{leaf} for leaves are compulsory:

- \texttt{members} total number of leaves in the branch
- \texttt{height} numeric non-negative height at which the node is plotted.
- \texttt{midpoint} numeric horizontal distance of the node from the left border (the leftmost leaf) of the branch (unit 1 between all leaves). This is used for \texttt{plot(*, center = FALSE)}.
- \texttt{label} character; the label of the node
- \texttt{x.member} for \texttt{cut()}\$upper, the number of former \texttt{members}; more generally a substitute for the \texttt{members} component used for 'horizontal' (when \texttt{horiz = FALSE}, else 'vertical') alignment.
- \texttt{edgetext} character; the label for the edge leading to the node
- \texttt{nodePar} a named list (of length-1 components) specifying node-specific attributes for \texttt{points} plotting, see the \texttt{nodePar} argument above.
- \texttt{edgePar} a named list (of length-1 components) specifying attributes for \texttt{segments} plotting of the edge leading to the node, and drawing of the \texttt{edgetext} if available, see the \texttt{edgePar} argument above.
- \texttt{leaf} logical, if \texttt{TRUE}, the node is a leaf of the tree.

\texttt{cut.dendrogram()} returns a list with components \$upper and \$lower, the first is a truncated version of the original tree, also of class \texttt{dendrogram}, the latter a list with the branches obtained from cutting the tree, each a \texttt{dendrogram}.

There are \texttt{[, print, and str} methods for "dendrogram" objects where the first one (extraction) ensures that selecting sub-branches keeps the class, i.e., returns a dendrogram even if only a leaf.

On the other hand, \texttt{[} (single bracket) extraction returns the underlying list structure.

Objects of class "hclust" can be converted to class "dendrogram" using method \texttt{as.dendrogram()}, and since R 2.13.0, there is also a \texttt{as.hclust()} method as an inverse.

\texttt{rev.dendrogram} simply returns the dendrogram \( x \) with reversed nodes, see also \texttt{reorder.dendrogram}.

The \texttt{merge(x, y, ...)} method merges two or more dendrograms into a new one which has \( x \) and \( y \) (and optional further arguments) as branches. Note that before R 3.1.2, \texttt{adjust} = "none" was used implicitly, which is invalid when, e.g., the dendrograms are from \texttt{as.dendrogram(hclust(..))}. 
nobs(object) returns the total number of leaves (the members attribute, see above).
is.leaf(object) returns logical indicating if object is a leaf (the most simple dendrogram).
plotNode() and plotNodelimit() are helper functions.

Warning

Some operations on dendrograms (including plotting) make use of recursion. For very deep trees it may be necessary to increase options("expressions"): if you do you are likely to need to set the C stack size larger than the default where possible.

Note

plot(): When using type = "triangle", center = TRUE often looks better.
str(d): If you really want to see the internal structure, use str(unclass(d)) instead.

See Also
dendrapply for applying a function to each node. order.dendrogram and reorder.dendrogram; further, the labels method.

Examples

require(graphics); require(stats)

hc <- hclust(dist(USArrests), "ave")
dend1 <- as.dendrogram(hc) # "print()" method
str(dend1) # "str()" method
str(dend1, max = 2, last.str = "\") # only the first two sub-levels
oo <- options(str.dendrogram.last = "\") # yet another possibility
str(dend1, max = 2) # only the first two sub-levels
options(oo) # .. resetting them

op <- par(mfrow = c(2,2), mar = c(5,2,1,4))
plot(dend1) ## "triangle" type and show inner nodes:
plot(dend1, nodePar = list(pch = c(1,NA), cex = 0.8, lab.cex = 0.8),
     type = "t", center = TRUE)
plot(dend1, edgePar = list(col = 1:2, lty = 2:3),
     dLeaf = 1, edge.root = TRUE)
plot(dend1, nodePar = list(pch = 2:1, cex = .4*2:1, col = 2:3),
     horiz = TRUE)

## simple test for as.hclust() as the inverse of as.dendrogram():
stopifnot(identical(as.hclust(dend1)[1:4], hc[1:4]))

dend2 <- cut(dend1, h = 70)
plot(dend2$upper) ## leaves are wrong horizontally:
plot(dend2$upper, nodePar = list(pch = c(1,7), col = 2:1))
## dend2$lower is *NOT* a dendrogram, but a list of .. :
plot(dend2$lower[[2]], nodePar = list(col = 4), horiz = TRUE, type = "tr")
## "inner" and "leaf" edges in different type & color:
plot(dend2$lower[[2]], nodePar = list(col = 1),
     edgePar = list(lty = 1:2, col = 2:1), edge.root = TRUE)
par(op)
density

The (S3) generic function density computes kernel density estimates. Its default method does so with the given kernel and bandwidth for univariate observations.

Usage

density(x, ...)  # Default S3 method:
density(x, bw = "nrd0", adjust = 1,
density

kernel = c("gaussian", "epanechnikov", "rectangular",  
"triangular", "biweight",  
"cosine", "optcosine"),
weights = NULL, window = kernel, width,
give.Rkern = FALSE,
  n = 512, from, to, cut = 3, na.rm = FALSE, ...)

Arguments

x          the data from which the estimate is to be computed.
bw         the smoothing bandwidth to be used. The kernels are scaled such that this is the  
            standard deviation of the smoothing kernel. (Note this differs from the reference  
            books cited below, and from S-PLUS.)
            bw can also be a character string giving a rule to choose the bandwidth. See  
            bw.nrd.
            The default, "nrd0", has remained the default for historical and compatibility  
            reasons, rather than as a general recommendation, where e.g., "SJ" would rather  
            fit, see also Venables and Ripley (2002).
            The specified (or computed) value of bw is multiplied by adjust.
adjust      the bandwidth used is actually adjust*bw. This makes it easy to specify values  
            like ‘half the default’ bandwidth.
kernel, window a character string giving the smoothing kernel to be used. This must be one of  
            "gaussian", "rectangular", "triangular", "epanechnikov", "biweight",  
            "cosine" or "optcosine", with default "gaussian", and may be abbreviated  
            to a unique prefix (single letter).
            "cosine" is smoother than "optcosine", which is the usual 'cosine' kernel in  
            the literature and almost MSE-efficient. However, "cosine" is the version used  
            by S.
weights     numeric vector of non-negative observation weights, hence of same length as x.  
            The default NULL is equivalent to weights = rep(1/nx, nx) where nx is the  
            length of (the finite entries of) x[].
width       this exists for compatibility with S; if given, and bw is not, will set bw to width  
            if this is a character string, or to a kernel-dependent multiple of width if this  
            is numeric.
give.Rkern  logical; if true, no density is estimated, and the ‘canonical bandwidth’ of the  
            chosen kernel is returned instead.
n           the number of equally spaced points at which the density is to be estimated.  
            When n > 512, it is rounded up to a power of 2 during the calculations (as fft  
            is used) and the final result is interpolated by approx. So it almost always makes  
            sense to specify n as a power of two.
from, to           the left and right-most points of the grid at which the density is to be estimated;  
            the defaults are cut * bw outside of range(x).
cut           by default, the values of from and to are cut bandwidths beyond the extremes  
            of the data. This allows the estimated density to drop to approximately zero at  
            the extremes.
na.rm         logical; if TRUE, missing values are removed from x. If FALSE any missing values  
            cause an error.
...         further arguments for (non-default) methods.
Details

The algorithm used in `density.default` disperses the mass of the empirical distribution function over a regular grid of at least 512 points and then uses the fast Fourier transform to convolve this approximation with a discretized version of the kernel and then uses linear approximation to evaluate the density at the specified points.

The statistical properties of a kernel are determined by $\sigma_K^2 = \int t^2 K(t) dt$ which is always $= 1$ for our kernels (and hence the bandwidth `bw` is the standard deviation of the kernel) and $R(K) = \int K^2(t) dt$. MSE-equivalent bandwidths (for different kernels) are proportional to $\sigma_K R(K)$ which is scale-invariant and for our kernels equal to $R(K)$. This value is returned when `give.Rkern = TRUE`. See the examples for using exact equivalent bandwidths.

Infinite values in `x` are assumed to correspond to a point mass at $\pm \text{Inf}$ and the density estimate is of the sub-density on $(-\text{Inf}, +\text{Inf})$.

Value

If `give.Rkern` is true, the number $R(K)$, otherwise an object with class "density" whose underlying structure is a list containing the following components.

- `x`: the $n$ coordinates of the points where the density is estimated.
- `y`: the estimated density values. These will be non-negative, but can be zero.
- `bw`: the bandwidth used.
- `n`: the sample size after elimination of missing values.
- `call`: the call which produced the result.
- `data.name`: the deparsed name of the `x` argument.
- `has.na`: logical, for compatibility (always FALSE).

The `print` method reports `summary` values on the `x` and `y` components.

---

deriv     Symbolic and Algorithmic Derivatives of Simple Expressions

description

Compute derivatives of simple expressions, symbolically.

Usage

d (expr, name)
deriv(expr, ...)
deriv3(expr, ...)

## Default S3 method:
deriv(expr, namevec, function.arg = NULL, tag = ".expr",
    hessian = FALSE, ...)
## S3 method for class 'formula'
deriv(expr, namevec, function.arg = NULL, tag = ".expr",
    hessian = FALSE, ...)

## Default S3 method:
deriv3(expr, namevec, function.arg = NULL, tag = ".expr",
    hessian = TRUE, ...)
## S3 method for class 'formula'
deriv3(expr, namevec, function.arg = NULL, tag = ".expr",
    hessian = TRUE, ...)
Arguments

expr A expression or call or (except D) a formula with no lhs.
name, namevec character vector, giving the variable names (only one for \( D() \)) with respect to which derivatives will be computed.
function.arg If specified and non-NULL, a character vector of arguments for a function return, or a function (with empty body) or TRUE, the latter indicating that a function with argument names namevec should be used.
tag character; the prefix to be used for the locally created variables in result.
hessian a logical value indicating whether the second derivatives should be calculated and incorporated in the return value.
... arguments to be passed to or from methods.

Details

\( D \) is modelled after its S namesake for taking simple symbolic derivatives. \( \text{deriv} \) is a generic function with a default and a formula method. It returns a call for computing the expr and its (partial) derivatives, simultaneously. It uses so-called algorithmic derivatives. If function.arg is a function, its arguments can have default values, see the \( \text{fx} \) example below.

Currently, \( \text{deriv.formula} \) just calls \( \text{deriv.default} \) after extracting the expression to the right of \(~\).

\( \text{deriv3} \) and its methods are equivalent to \( \text{deriv} \) and its methods except that hessian defaults to TRUE for \( \text{deriv3} \).

The internal code knows about the arithmetic operators \(+\), \(-\), \(*\), \(/\), and \(^{\wedge}\), and the single-variable functions \( \exp, \log, \sin, \cos, \tan, \sinh, \cosh, \sqrt{\text{sqrt}}, \text{pnorm}, \text{dnorm}, \text{asin}, \text{acos}, \text{atan}, \text{gamma}, \text{digamma} \) and \( \text{trigamma} \), as well as \( \text{psigamma} \) for one or two arguments (but derivative only with respect to the first). (Note that only the standard normal distribution is considered.)

Value

\( D \) returns a call and therefore can easily be iterated for higher derivatives.
\( \text{deriv} \) and \( \text{deriv3} \) normally return an expression object whose evaluation returns the function values with a "gradient" attribute containing the gradient matrix. If hessian is TRUE the evaluation also returns a "hessian" attribute containing the Hessian array.

If function.arg is not NULL, \( \text{deriv} \) and \( \text{deriv3} \) return a function with those arguments rather than an expression.

References

\( \text{nlm} \) and \( \text{optim} \) for numeric minimization which could make use of derivatives,
Examples

## formula argument:
```r
dx2x <- deriv(~ x^2, "x") ; dx2x
```

## Not run: expression:
```r
.x.value <- x^2
.grad <- array(0, c(length(.value), 1), list(NULL, c("x")))
.grad[, "x"] <- 2 * x
.attr(.value, "gradient") <- .grad

}
```

## End(Not run)
```
mode(dx2x)
x <- -1:2
eval(dx2x)
```

## Something 'tougher':
```r
trig.exp <- expression(sin(cos(x + y^2)))
(D.sc <- D(trig.exp, "x") )
all.equal(D(trig.exp[[1]], "x"), D.sc)
```
```r
(dxy <- deriv(trig.exp, c("x", "y")))
y <- 1
eval(dxy)
eval(D.sc)
```

## function returned:
```r
deriv((y = sin(cos(x) * y)), c("x","y"), func = TRUE)
```

## function with defaulted arguments:
```r
(fx <- deriv(y = b0 + b1 * 2^(-x/th), c("b0", "b1", "th"),
             function(b0, b1, th, x = 1:7)() )
```
```r
fx(2, 3, 4)
```

## Higher derivatives
```r
deriv3(y = b0 + b1 * 2^(-x/th), c("b0", "b1", "th"),
       c("b0", "b1", "th", "x") )
```

## Higher derivatives:
```r
DD <- function(expr, name, order = 1) {
  if(order < 1) stop("order' must be >= 1")
  if(order == 1) D(expr, name)
  else DD(D(expr, name), name, order - 1)
}
```
```r
DD(expression(sin(x^2)), "x", 3)
```

## showing the limits of the internal "simplify()":

## Not run:
```r
-sin(x^2) * (2 * x) * 2 + ((cos(x^2) * (2 * x) * (2 * x) + sin(x^2) * 2) * (2 * x) + sin(x^2) * (2 * x) * 2)
```

## End(Not run)
**Description**

Returns the deviance of a fitted model object.

**Usage**

`deviance(object, ...)`

**Arguments**

- `object`: an object for which the deviance is desired.
- `...`: additional optional argument.

**Details**

This is a generic function which can be used to extract deviances for fitted models. Consult the individual modeling functions for details on how to use this function.

**Value**

The value of the deviance extracted from the object object.

**References**

**See Also**

`df.residual`, `extractAIC`, `glm`, `lm`.

---

**df.residual**

*Residual Degrees-of-Freedom*

**Description**

Returns the residual degrees-of-freedom extracted from a fitted model object.

**Usage**

`df.residual(object, ...)`

**Arguments**

- `object`: an object for which the degrees-of-freedom are desired.
- `...`: additional optional arguments.

**Details**

This is a generic function which can be used to extract residual degrees-of-freedom for fitted models. Consult the individual modeling functions for details on how to use this function.

The default method just extracts the `df.residual` component.
Value

The value of the residual degrees-of-freedom extracted from the object x.

See Also

deviance, glm, lm.

diffinv  
Discrete Integration: Inverse of Differencing

Description

Computes the inverse function of the lagged differences function diff.

Usage

diffinv(x, ...)  
## Default S3 method:  
diffinv(x, lag = 1, differences = 1, xi, ...)  
## S3 method for class 'ts'  
diffinv(x, lag = 1, differences = 1, xi, ...)

Arguments

x a numeric vector, matrix, or time series.
lag a scalar lag parameter.
differences an integer representing the order of the difference.
xi a numeric vector, matrix, or time series containing the initial values for the integrals. If missing, zeros are used.
... arguments passed to or from other methods.

Details

diffinv is a generic function with methods for class "ts" and default for vectors and matrices. Missing values are not handled.

Value

A numeric vector, matrix, or time series (the latter for the "ts" method) representing the discrete integral of x.

Author(s)

A. Trapletti

diff
Examples

```r
s <- 1:10
d <- diff(s)
diffinv(d, xi = 1)
```

---

**Description**

This function computes and returns the distance matrix computed by using the specified distance measure to compute the distances between the rows of a data matrix.

**Usage**

```r
dist(x, method = "euclidean", diag = FALSE, upper = FALSE, p = 2)
```

```r
as.dist(m, diag = FALSE, upper = FALSE)
```

```r
# Default S3 method:
as.dist(m, diag = FALSE, upper = FALSE)
```

```r
# S3 method for class 'dist'
print(x, diag = NULL, upper = NULL,
digits = getOption("digits"), justify = "none",
right = TRUE, ...)
```

```r
# S3 method for class 'dist'
as.matrix(x, ...)
```

**Arguments**

- `x` a numeric matrix, data frame or "dist" object.
- `method` the distance measure to be used. This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". Any unambiguous substring can be given.
- `diag` logical value indicating whether the diagonal of the distance matrix should be printed.
- `upper` logical value indicating whether the upper triangle of the distance matrix should be printed.
- `p` The power of the Minkowski distance.
- `m` An object with distance information to be converted to a "dist" object. For the default method, a "dist" object, or a matrix (of distances) or an object which can be coerced to such a matrix using `as.matrix()`. (Only the lower triangle of the matrix is used, the rest is ignored).
- `digits`, `justify` passed to `format` inside of `print()`. 
- `right`, `...` further arguments, passed to other methods.
Details

Available distance measures are (written for two vectors \(x\) and \(y\)):

euclidean: Usual distance between the two vectors (2 norm aka \(L_2\)), \(\sqrt{\sum_i(x_i - y_i)^2}\).

maximum: Maximum distance between two components of \(x\) and \(y\) (supremum norm).

manhattan: Absolute distance between the two vectors (1 norm aka \(L_1\)).

canberra: \(\sum_i |x_i - y_i|/|x_i + y_i|\). Terms with zero numerator and denominator are omitted from the sum and treated as if the values were missing.

This is intended for non-negative values (e.g., counts): taking the absolute value of the denominator is a 1998 \(R\) modification to avoid negative distances.

binary: (aka asymmetric binary): The vectors are regarded as binary bits, so non-zero elements are ‘on’ and zero elements are ‘off’. The distance is the proportion of bits in which only one is on amongst those in which at least one is on.

minkowski: The \(p\) norm, the \(p\)th root of the sum of the \(p\)th powers of the differences of the components.

Missing values are allowed, and are excluded from all computations involving the rows within which they occur. Further, when Inf values are involved, all pairs of values are excluded when their contribution to the distance gave NaN or NA. If some columns are excluded in calculating a Euclidean, Manhattan, Canberra or Minkowski distance, the sum is scaled up proportionally to the number of columns used. If all pairs are excluded when calculating a particular distance, the value is NA.

The "dist" method of as.matrix() and as.dist() can be used for conversion between objects of class "dist" and conventional distance matrices.

as.dist() is a generic function. Its default method handles objects inheriting from class "dist", or coercible to matrices using as.matrix(). Support for classes representing distances (also known as dissimilarities) can be added by providing an as.matrix() or, more directly, an as.dist method for such a class.

Value

dist returns an object of class "dist".

The lower triangle of the distance matrix stored by columns in a vector, say do. If \(n\) is the number of observations, i.e., \(n \leftarrow \text{attr}(\text{do}, \text{"Size"})\), then for \(i < j \leq n\), the dissimilarity between (row) \(i\) and \(j\) is \(\text{do}[n*(i-1) - i*(i-1)/2 + j-i]\). The length of the vector is \(n*(n-1)/2\), i.e., of order \(n^2\).

The object has the following attributes (besides "class" equal to "dist"):

- **Size**: integer, the number of observations in the dataset.
- **Labels**: optionally, contains the labels, if any, of the observations of the dataset.
- **Diag, Upper**: logicals corresponding to the arguments diag and upper above, specifying how the object should be printed.
- **call**: optionally, the call used to create the object.
- **method**: optionally, the distance method used; resulting from dist(), the (match.arg()ed) method argument.

Examples

require(graphics)

x <- matrix(rnorm(100), nrow = 5)
dist(x)
dist(x, diag = TRUE)
dist(x, upper = TRUE)
m <- as.matrix(dist(x))
d <- as.dist(m)
stopifnot(d == dist(x))

## Use correlations between variables "as distance"
dd <- as.dist((1 - cor(USJudgeRatings))/2)
round(1000 * dd) # (prints more nicely)
plot(hclust(dd)) # to see a dendrogram of clustered variables

## example of binary and canberra distances.
x <- c(0, 0, 1, 1, 1)
y <- c(1, 0, 1, 1, 0, 1)
dist(rbind(x, y), method = "binary")
## answer 0.4 = 2/5

dist(rbind(x, y), method = "canberra")
## answer 2 * (6/5)

## To find the names
labels(euroidist)

## Examples involving "Inf" :
## 1)
x[6] <- Inf
(m2 <- rbind(x, y))
dist(m2, method = "binary") # warning, answer 0.5 = 2/4
## These all give "Inf":
stopifnot(Inf == dist(m2, method = "euclidean"),
Inf == dist(m2, method = "maximum"),
Inf == dist(m2, method = "manhattan"))
## "Inf" is same as very large number:
x1 <- x; x[6] <<- 1e100
stopifnot(dist(cbind(x, y), method = "canberra") ==
print(dist(cbind(x1, y), method = "canberra")))
## 2)
Distributions

Distributions in the stats package

Description

Density, cumulative distribution function, quantile function and random variate generation for many standard probability distributions are available in the stats package.

Details

The functions for the density/mass function, cumulative distribution function, quantile function and random variate generation are named in the form dxxx, pxxx, qxxx and rxxx respectively.

For the beta distribution see dbeta.
For the binomial (including Bernoulli) distribution see dbinom.
For the Cauchy distribution see dcauchy.
For the chi-squared distribution see dchisq.
For the exponential distribution see dexp.
For the F distribution see df.
For the gamma distribution see dgamma.
For the geometric distribution see dgeom. (This is also a special case of the negative binomial.)
For the hypergeometric distribution see dhyper.
For the log-normal distribution see dlnorm.
For the multinomial distribution see dmultinom.
For the negative binomial distribution see dnbino.
For the normal distribution see dnorm.
For the Poisson distribution see dpois.
For the Student’s t distribution see dt.
For the uniform distribution see dunif.
For the Weibull distribution see dweibull.
For less common distributions of test statistics see pbirthday, dsignrank, ptukey and dwilcox (and see the ‘See Also’ section of cor.test).

RNG about random number generation in R.
The CRAN task view on distributions, http://cran.r-project.org/web/views/Distributions.html, mentioning several CRAN packages for additional distributions.
dummy.coef  

Extract Coefficients in Original Coding

Description

This extracts coefficients in terms of the original levels of the coefficients rather than the coded variables.

Usage

dummy.coef(object, ...)

## S3 method for class 'lm'
dummy.coef(object, use.na = FALSE, ...)

## S3 method for class 'aovlist'
dummy.coef(object, use.na = FALSE, ...)

Arguments

object  
a linear model fit.

use.na  
logical flag for coefficients in a singular model. If use.na is true, undetermined coefficients will be missing; if false they will get one possible value.

...  
arguments passed to or from other methods.

Details

A fitted linear model has coefficients for the contrasts of the factor terms, usually one less in number than the number of levels. This function re-expresses the coefficients in the original coding; as the coefficients will have been fitted in the reduced basis, any implied constraints (e.g., zero sum for contr.helmert or contr.sum) will be respected. There will be little point in using dummy.coef for contr.treatment contrasts, as the missing coefficients are by definition zero.

The method used has some limitations, and will give incomplete results for terms such as poly(x, 2). However, it is adequate for its main purpose, aov models.

Value

A list giving for each term the values of the coefficients. For a multistratum aov model, such a list for each stratum.

Warning

This function is intended for human inspection of the output: it should not be used for calculations. Use coded variables for all calculations.

The results differ from S for singular values, where S can be incorrect.

ecdf

Examples

options(contrasts = c("contr.helmert", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
dummy.coef(npk.aov)
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
dummy.coef(npk.aovE)

ecdf

Empirical Cumulative Distribution Function

Description

Compute an empirical cumulative distribution function, with several methods for plotting, printing and computing with such an “ecdf” object.

Usage

ecdf(x)

## S3 method for class 'ecdf'
plot(x, ..., ylab="Fn(x)", verticals = FALSE,
     col.01line = "gray70", pch = 19)

## S3 method for class 'ecdf'
print(x, digits = getOption("digits") - 2, ...)

## S3 method for class 'ecdf'
summary(object, ...)

## S3 method for class 'ecdf'
quantile(x, ...)

Arguments

x, object numeric vector of the observations for ecdf; for the methods, an object inheriting from class "ecdf".

... arguments to be passed to subsequent methods, e.g., plot.stepfun for the plot method.

ylab label for the y-axis.

verticals see plot.stepfun.

col.01line numeric or character specifying the color of the horizontal lines at y = 0 and 1, see colors.

pch plotting character.

digits number of significant digits to use, see print.
Details

The e.c.d.f. (empirical cumulative distribution function) $F_n$ is a step function with jumps $i/n$ at observation values, where $i$ is the number of tied observations at that value. Missing values are ignored.

For observations $x = (x_1, x_2, \ldots, x_n)$, $F_n$ is the fraction of observations less or equal to $t$, i.e.,

$$F_n(t) = \frac{\#\{x_i \leq t\}}{n} = \frac{1}{n} \sum_{i=1}^{n} 1[x_i \leq t].$$

The function `plot.ecdf` which implements the `plot` method for `ecdf` objects, is implemented via a call to `plot.stepfun`; see its documentation.

Value

For `ecdf`, a function of class "ecdf", inheriting from the "stepfun" class, and hence inheriting a `knots()` method.

For the summary method, a summary of the knots of object with a "header" attribute.

The `quantile()` method computes the same quantiles as `quantile(x, ...)` would where `x` is the original sample.

Note

The objects of class "ecdf" are not intended to be used for permanent storage and may change structure between versions of R (and did at R 3.0.0). They can usually be re-created by

```r
eval(attr(old_obj, "call"), environment(old_obj))
```

since the data used is stored as part of the object’s environment.

Author(s)

Martin Maechler; fixes and new features by other R-core members.

**eff.aovlist**  
*Compute Efficiencies of Multistratum Analysis of Variance*

**Description**
Computes the efficiencies of fixed-effect terms in an analysis of variance model with multiple strata.

**Usage**
eff.aovlist(aovlist)

**Arguments**
aovlist  
The result of a call to aov with an Error term.
Details

Fixed-effect terms in an analysis of variance model with multiple strata may be estimable in more than one stratum, in which case there is less than complete information in each. The efficiency for a term is the fraction of the maximum possible precision (inverse variance) obtainable by estimating in just that stratum. Under the assumption of balance, this is the same for all contrasts involving that term.

This function is used to pick strata in which to estimate terms in `model.tables.aovlist` and `se.contrast.aovlist`.

In many cases terms will only occur in one stratum, when all the efficiencies will be one: this is detected and no further calculations are done.

The calculation used requires orthogonal contrasts for each term, and will throw an error if non-orthogonal contrasts (e.g., treatment contrasts or an unbalanced design) are detected.

Value

A matrix giving for each non-pure-error stratum (row) the efficiencies for each fixed-effect term in the model.

References

`aov.model.tables.aovlist, se.contrast.aovlist`

Examples

```r
## An example from Yates (1932),
## a 2*3 design in 2 blocks replicated 4 times

Block <- gl(8, 4)
A <- factor(c(0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1))
B <- factor(c(0,0,1,1,0,0,1,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1))
C <- factor(c(0,1,1,0,1,0,1,0,1,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1))
aovdat <- data.frame(Block, A, B, C, Yield)
old <- getOption("contrasts")
options(contrasts = c("contr.helmert", "contr.poly"))
(fit <- aov(Yield ~ A*B*C + Error(Block), data = aovdat))
eff.aovlist(fit)
options(contrasts = old)
```
**effects**

*Effects from Fitted Model*

**Description**

Returns (orthogonal) effects from a fitted model, usually a linear model. This is a generic function, but currently only has a method for objects inheriting from classes "lm" and "glm".

**Usage**

```r
effects(object, ...) 
```

```r
## S3 method for class 'lm'
effects(object, set.sign = FALSE, ...)
```

**Arguments**

- `object`: an R object; typically, the result of a model fitting function such as `lm`.
- `set.sign`: logical. If TRUE, the sign of the effects corresponding to coefficients in the model will be set to agree with the signs of the corresponding coefficients, otherwise the sign is arbitrary.
- `...`: arguments passed to or from other methods.

**Details**

For a linear model fitted by `lm` or `aov`, the effects are the uncorrelated single-degree-of-freedom values obtained by projecting the data onto the successive orthogonal subspaces generated by the QR decomposition during the fitting process. The first \( r \) (the rank of the model) are associated with coefficients and the remainder span the space of residuals (but are not associated with particular residuals).

Empty models do not have effects.

**Value**

A (named) numeric vector of the same length as `residuals`, or a matrix if there were multiple responses in the fitted model, in either case of class "coef".

The first \( r \) rows are labelled by the corresponding coefficients, and the remaining rows are unlabelled. Note that in rank-deficient models the corresponding coefficients will be in a different order if pivoting occurred.

**References**

**See Also**

- `coef`
Examples

```r
y <- c(1:3, 7, 5)
x <- c(1:3, 6:7)
( ee <- effects(lm(y ~ x)) )
c( round(ee - effects(lm(y~10 - I(x+3.8)), 3) )
# just the first is different
```

---

**Description**

Embeds the time series `x` into a low-dimensional Euclidean space.

**Usage**

```r
embed(x, dimension = 1)
```

**Arguments**

- `x` a numeric vector, matrix, or time series.
- `dimension` a scalar representing the embedding dimension.

**Details**

Each row of the resulting matrix consists of sequences `x[t]`, `x[t-1]`, ..., `x[t-dimension+1]`, where `t` is the original index of `x`. If `x` is a matrix, i.e., `x` contains more than one variable, then `x[t]` consists of the `t`th observation on each variable.

**Value**

A matrix containing the embedded time series `x`.

**Author(s)**

A. Trapletti, B.D. Ripley

**Examples**

```r
x <- 1:10
embed(x, 3)
```
expand.model.frame

Add new variables to a model frame

Description

Evaluates new variables as if they had been part of the formula of the specified model. This ensures that the same na.action and subset arguments are applied and allows, for example, \( x \) to be recovered for a model using \( \sin(x) \) as a predictor.

Usage

```r
expand.model.frame(model, extras,
                   envir = environment(formula(model)),
                   na.expand = FALSE)
```

Arguments

- `model`: a fitted model
- `extras`: one-sided formula or vector of character strings describing new variables to be added
- `envir`: an environment to evaluate things in
- `na.expand`: logical; see below

Details

If `na.expand = FALSE` then NA values in the extra variables will be passed to the `na.action` function used in `model`. This may result in a shorter data frame (with `na.omit`) or an error (with `na.fail`). If `na.expand = TRUE` the returned data frame will have precisely the same rows as `model.frame(model)`, but the columns corresponding to the extra variables may contain NA.

Value

A data frame.

See Also

`model.frame`, `predict`

Examples

```r
model <- lm(log(Volume) ~ log(Girth) + log(Height), data = trees)
expand.model.frame(model, ~ Girth) # prints data.frame like

dd <- data.frame(x = 1:5, y = rnorm(5), z = c(1,2,NA,4,5))
model <- glm(y ~ x, data = dd, subset = 1:4, na.action = na.omit)
expand.model.frame(model, "z", na.expand = FALSE) # = default
expand.model.frame(model, "z", na.expand = TRUE)
```
The Exponential Distribution

Description

Density, distribution function, quantile function and random generation for the exponential distribution with rate rate (i.e., mean 1/rate).

Usage

dexp(x, rate = 1, log = FALSE)
pexp(q, rate = 1, lower.tail = TRUE, log.p = FALSE)
qexp(p, rate = 1, lower.tail = TRUE, log.p = FALSE)
rexp(n, rate = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
rate vector of rates.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are P[X ≤ x], otherwise, P[X > x].

Details

If rate is not specified, it assumes the default value of 1.

The exponential distribution with rate λ has density

\[ f(x) = \lambda e^{-\lambda x} \]

for \( x \geq 0 \).

Value

dexp gives the density, pexp gives the distribution function, qexp gives the quantile function, and rexp generates random deviates.

The length of the result is determined by n for rexp, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is -pexp(t, r, lower = FALSE, log = TRUE).
### Source

dexp, pexp and qexp are all calculated from numerically stable versions of the definitions.

rexp uses

### Examples

dexp(1) - exp(-1) #-> 0

```r
## a fast way to generate *sorted* U[0,1] random numbers:
rsunif <- function(n) { n1 <- n+1
  cE <- cumsum(rexp(n1)); cE[seq_len(n)]/cE[n1] }
plot(rsunif(1000), ylim=0:1, pch=".")
abline(0,1/(1000+1), col=adjustcolor(1, 0.5))
```

---

**extractAIC**  
*Extract AIC from a Fitted Model*

### Description

Computes the (generalized) Akaike An Information Criterion for a fitted parametric model.

### Usage

```r
extractAIC(fit, scale, k = 2, ...)
```

### Arguments

- **fit**: fitted model, usually the result of a fitter like `lm`.
- **scale**: optional numeric specifying the scale parameter of the model, see `scale` in `step`. Currently only used in the "lm" method, where `scale` specifies the estimate of the error variance, and `scale = 0` indicates that it is to be estimated by maximum likelihood.
- **k**: numeric specifying the ‘weight’ of the *equivalent degrees of freedom* (≡ `edf`) part in the AIC formula.
- **...**: further arguments (currently unused in base R).
Details

This is a generic function, with methods in base \( \mathbb{R} \) for classes "aov", "glm" and "lm" as well as for "negbin" (package \texttt{MASS}) and "coxph" and "survreg" (package \texttt{survival}).

The criterion used is

\[
AIC = -2 \log L + k \times \text{edf},
\]

where \( L \) is the likelihood and \( \text{edf} \) the equivalent degrees of freedom (i.e., the number of free parameters for usual parametric models) of \( \text{fit} \).

For linear models with unknown scale (i.e., for \texttt{lm} and \texttt{aov}), \( -2 \log L \) is computed from the \texttt{deviance} and uses a different additive constant to \texttt{logLik} and hence \texttt{AIC}. If \( RSS \) denotes the (weighted) residual sum of squares then \texttt{extractAIC} uses for \( -2 \log L \) the formulae \( RSS/s - n \) (corresponding to Mallows’ \( C_p \)) in the case of known scale \( s \) and \( n \log(RSS/n) \) for unknown scale. \texttt{AIC} only handles unknown scale and uses the formula \( n \log(RSS/n) + n + n \log 2\pi - \sum \log w \) where \( w \) are the weights. Further \texttt{AIC} counts the scale estimation as a parameter in the \texttt{edf} and \texttt{extractAIC} does not.

For \texttt{glm} fits the family’s \texttt{aic()} function is used to compute the AIC: see the note under \texttt{logLik} about the assumptions this makes.

\( k = 2 \) corresponds to the traditional \( \text{AIC} \), using \( k = 1 \log(n) \) provides the \( \text{BIC} \) (Bayesian IC) instead.

Note that the methods for this function may differ in their assumptions from those of methods for \texttt{AIC} (usually via a method for \texttt{logLik}). We have already mentioned the case of "lm" models with estimated scale, and there are similar issues in the "glm" and "negbin" methods where the dispersion parameter may or may not be taken as ‘free’. This is immaterial as \texttt{extractAIC} is only used to compare models of the same class (where only differences in AIC values are considered).

Value

A numeric vector of length 2, with first and second elements giving

- \( \text{edf} \): the ‘equivalent degrees of freedom’ for the fitted model \( \text{fit} \).
- \( \text{AIC} \): the (generalized) Akaike Information Criterion for \( \text{fit} \).

Note

This function is used in \texttt{add1}, \texttt{drop1} and \texttt{step} and the similar functions in package \texttt{MASS} from which it was adopted.

Author(s)

B. D. Ripley

References

**Examples**

```r
glm <- example(glm)
extractAIC(glm, D93) >>> 5 15.129
```

**factanal**

*Factor Analysis*

**Description**

Perform maximum-likelihood factor analysis on a covariance matrix or data matrix.

**Usage**

```r
factanal(x, factors, data = NULL, covmat = NULL, n.obs = NA,
          subset, na.action, start = NULL,
          scores = c("none", "regression", "Bartlett"),
          rotation = "varimax", control = NULL, ...)
```

**Arguments**

- `x` A formula or a numeric matrix or an object that can be coerced to a numeric matrix.
- `factors` The number of factors to be fitted.
- `data` An optional data frame (or similar: see `model.frame`), used only if `x` is a formula. By default the variables are taken from `environment(formula)`.
- `covmat` A covariance matrix, or a covariance list as returned by `cov.wt`. Of course, correlation matrices are covariance matrices.
- `n.obs` The number of observations, used if `covmat` is a covariance matrix.
- `subset` A specification of the cases to be used, if `x` is used as a matrix or formula.
- `na.action` The `na.action` to be used if `x` is used as a formula.
- `start` NULL or a matrix of starting values, each column giving an initial set of uniquenesses.
- `scores` Type of scores to produce, if any. The default is none, "regression" gives Thompson’s scores, "Bartlett" gives Bartlett’s weighted least-squares scores. Partial matching allows these names to be abbreviated.
- `rotation` character. "none" or the name of a function to be used to rotate the factors: it will be called with first argument the loadings matrix, and should return a list with component `loadings` giving the rotated loadings, or just the rotated loadings.
- `control` A list of control values,
  - `nstart` The number of starting values to be tried if `start = NULL`. Default 1.
  - `trace` logical. Output tracing information? Default FALSE.
  - `lower` The lower bound for uniquenesses during optimization. Should be > 0. Default 0.005.
  - `opt` A list of control values to be passed to `optim`’s control argument.
  - `rotate` a list of additional arguments for the rotation function.
  - `...` Components of control can also be supplied as named arguments to `factanal`. 
Details

The factor analysis model is

\[ x = \Lambda f + e \]

for a \( p \)-element row-vector \( x \), a \( p \times k \) matrix \( \Lambda \) of loadings, a \( k \)-element vector \( f \) of scores and a \( p \)-element vector \( e \) of errors. None of the components other than \( x \) is observed, but the major restriction is that the scores be uncorrelated and of unit variance, and that the errors be independent with variances \( \Psi \), the uniquenesses. It is also common to scale the observed variables to unit variance, and done in this function.

Thus factor analysis is in essence a model for the correlation matrix of \( x \),

\[ \Sigma = \Lambda' \Lambda + \Psi \]

There is still some indeterminacy in the model for it is unchanged if \( \Lambda \) is replaced by \( G \Lambda \) for any orthogonal matrix \( G \). Such matrices \( G \) are known as rotations (although the term is applied also to non-orthogonal invertible matrices).

If covmat is supplied it is used. Otherwise \( x \) is used if it is a matrix, or a formula \( x \) is used with data to construct a model matrix, and that is used to construct a covariance matrix. (It makes no sense for the formula to have a response, and all the variables must be numeric.) Once a covariance matrix is found or calculated from \( x \), it is converted to a correlation matrix for analysis. The correlation matrix is returned as component correlation of the result.

The fit is done by optimizing the log likelihood assuming multivariate normality over the uniquenesses. (The maximizing loadings for given uniquenesses can be found analytically: Lawley & Maxwell (1971, p. 27).) All the starting values supplied in start are tried in turn and the best fit obtained is used. If start = NULL then the first fit is started at the value suggested by Jöreskog (1963) and given by Lawley & Maxwell (1971, p. 31), and then control$start = -1 other values are tried, randomly selected as equal values of the uniquenesses.

The uniquenesses are technically constrained to lie in [0, 1], but near-zero values are problematical, and the optimization is done with a lower bound of control$lower, default 0.005 (Lawley & Maxwell, 1971, p. 32).

Scores can only be produced if a data matrix is supplied and used. The first method is the regression method of Thomson (1951), the second the weighted least squares method of Bartlett (1937, 8). Both are estimates of the unobserved scores \( f \). Thomson’s method regresses (in the population) the unknown \( f \) on \( x \) to yield

\[ f = \Lambda \Sigma^{-1} x \]

and then substitutes the sample estimates of the quantities on the right-hand side. Bartlett’s method minimizes the sum of squares of standardized errors over the choice of \( f \), given (the fitted) \( \Lambda \).

If \( x \) is a formula then the standard NA-handling is applied to the scores (if requested): see napredict.

The print method (documented under loadings) follows the factor analysis convention of drawing attention to the patterns of the results, so the default precision is three decimal places, and small loadings are suppressed.

Value

An object of class "factanal" with components

loadings A matrix of loadings, one column for each factor. The factors are ordered in decreasing order of sums of squares of loadings, and given the sign that will make the sum of the loadings positive. This is of class "loadings": see loadings for its print method.

uniquenesses The uniquenesses computed.
correlation The correlation matrix used.
criteria The results of the optimization: the value of the negative log-likelihood and information on the iterations used.
factors The argument factors.
dof The number of degrees of freedom of the factor analysis model.
method The method: always "mle".
rotmat The rotation matrix if relevant.
scores If requested, a matrix of scores. napredict is applied to handle the treatment of values omitted by the na.action.
n.obs The number of observations if available, or NA.
call The matched call.
na.action If relevant.
STATISTIC, PVAL The significance-test statistic and P value, if it can be computed.

Note
There are so many variations on factor analysis that it is hard to compare output from different programs. Further, the optimization in maximum likelihood factor analysis is hard, and many other examples we compared had less good fits than produced by this function. In particular, solutions which are 'Heywood cases' (with one or more uniquenesses essentially zero) are much more common than most texts and some other programs would lead one to believe.

Examples
# A little demonstration, v2 is just v1 with noise,
# and same for v4 vs. v3 and v6 vs. v5
# Last four cases are there to add noise
# and introduce a positive manifold (g factor)
v1 <- c(1,1,1,1,1,1,1,1,3,3,3,3,3,3,3,4,5,6)
v2 <- c(1,2,1,1,1,2,1,2,1,3,4,3,3,3,4,6,5)
v3 <- c(3,3,3,3,3,3,1,1,1,1,1,1,1,1,1,1,5,4,6)
v4 <- c(3,3,4,3,3,1,1,1,1,1,1,1,2,1,1,5,6,4)
factor.scope

**Compute Allowed Changes in Adding to or Dropping from a Formula**

**Description**

`add.scope` and `drop.scope` compute those terms that can be individually added to or dropped from a model while respecting the hierarchy of terms.

**Usage**

```r
add.scope(terms1, terms2)

drop.scope(terms1, terms2)

factor.scope(factor, scope)
```

**Arguments**

- `terms1`: the terms or formula for the base model.
- `terms2`: the terms or formula for the upper (add.scope) or lower (drop.scope) scope. If missing for `drop.scope` it is taken to be the null formula, so all terms (except any intercept) are candidates to be dropped.
- `factor`: the "factor" attribute of the terms of the base object.
- `scope`: a list with one or both components `drop` and `add` giving the "factor" attribute of the lower and upper scopes respectively.

**Details**

`factor.scope` is not intended to be called directly by users.

**Value**

For `add.scope` and `drop.scope` a character vector of terms labels. For `factor.scope`, a list with components `drop` and `add`, character vectors of terms labels.

```r
v5 <- c(1,1,1,1,3,3,3,3,3,1,1,1,6,4,5)
v6 <- c(1,1,1,2,1,3,3,4,3,1,1,2,1,6,5,4)
m1 <- cbind(v1,v2,v3,v4,v5,v6)
cor(m1)
factanal(m1, factors = 3) # varimax is the default
factanal(m1, factors = 3, rotation = "promax")
# The following shows the g factor as PC1
prcomp(m1) # signs may depend on platform

## formula interface
factanal(~v1+v2+v3+v4+v5+v6, factors = 3,
  scores = "Bartlett")$scores

Examples

add.scope(~ a + b + c + a:b, ~(a + b + c)^3)
# [1] "a:c" "b:c"
drop.scope(~ a + b + c + a:b)
# [1] "c" "a:b"

Description

Family objects provide a convenient way to specify the details of the models used by functions such as glm. See the documentation for glm for the details on how such model fitting takes place.

Usage

family(object, ...) 

binomial(link = "logit")
gaussian(link = "identity")
Gamma(link = "inverse")
inverse.gaussian(link = "1/mu^2")
poisson(link = "log")
quasi(link = "identity", variance = "constant")
quasibinomial(link = "logit")
quasipoisson(link = "log")

Arguments

link  a specification for the model link function. This can be a name/expression, a literal character string, a length-one character vector or an object of class "link-glm" (such as generated by make.link) provided it is not specified via one of the standard names given next.

The gaussian family accepts the links (as names) identity, log and inverse; the binomial family the links logit, probit, cauchit (corresponding to logistic, normal and Cauchy CDFs respectively) log and cloglog (complementary log-log); the Gamma family the links inverse, identity and log; the poisson family the links log, identity, and sqrt and the inverse Gaussian family the links 1/mu^2, inverse, identity and log.

The quasi family accepts the links logit, probit, cloglog, identity, inverse, log, 1/mu^2 and sqrt, and the function power can be used to create a power link function.

variance  for all families other than quasi, the variance function is determined by the family. The quasi family will accept the literal character string (or unquoted as a name/expression) specifications "constant", "mu(1-mu)", "mu", "mu^2" and "mu^3", a length-one character vector taking one of those values, or a list containing components varfun, validmu, dev.resids, initialize and name.
family

object the function family accesses the family objects which are stored within objects created by modelling functions (e.g., glm).

... further arguments passed to methods.

Details

family is a generic function with methods for classes "glm" and "lm" (the latter returning gaussian()).

For the binomial and quasibinomial families the response can be specified in one of three ways:

1. As a factor: 'success' is interpreted as the factor not having the first level (and hence usually of having the second level).
2. As a numerical vector with values between 0 and 1, interpreted as the proportion of successful cases (with the total number of cases given by the weights).
3. As a two-column integer matrix: the first column gives the number of successes and the second the number of failures.

The quasibinomial and quasipoisson families differ from the binomial and poisson families only in that the dispersion parameter is not fixed at one, so they can model over-dispersion. For the binomial case see McCullagh and Nelder (1989, pp. 124–8). Although they show that there is (under some restrictions) a model with variance proportional to mean as in the quasi-binomial model, note that glm does not compute maximum-likelihood estimates in that model. The behaviour of S is closer to the quasi- variants.

Value

An object of class "family" (which has a concise print method). This is a list with elements

family character: the family name.
link character: the link name.
linkfun function: the link.
linkinv function: the inverse of the link function.
variance function: the variance as a function of the mean.
dev.resids function giving the deviance residuals as a function of \( y, \mu, \text{wt} \).
aic function giving the AIC value if appropriate (but NA for the quasi- families). See logLik for the assumptions made about the dispersion parameter.
mu.eta function: derivative function(eta) \( d\mu/d\eta \).
initialize expression. This needs to set up whatever data objects are needed for the family as well as n (needed for AIC in the binomial family) and mustart (see glm).
valid.mu logical function. Returns TRUE if a mean vector mu is within the domain of variance.
valid.eta logical function. Returns TRUE if a linear predictor eta is within the domain of linkinv.
simulate (optional) function simulate(object, nsim) to be called by the "lm" method of simulate. It will normally return a matrix with nsim columns and one row for each fitted value, but it can also return a list of length nsim. Clearly this will be missing for 'quasi-' families.
Note

The link and variance arguments have rather awkward semantics for back-compatibility. The recommended way is to supply them as quoted character strings, but they can also be supplied unquoted (as names or expressions). In addition, they can also be supplied as a length-one character vector giving the name of one of the options, or as a list (for link, of class "link-glm"). The restrictions apply only to links given as names: when given as a character string all the links known to make.link are accepted.

This is potentially ambiguous: supplying link = logit could mean the unquoted name of a link or the value of object logit. It is interpreted if possible as the name of an allowed link, then as an object. (You can force the interpretation to always be the value of an object via logit[1].)

Author(s)

The design was inspired by S functions of the same names described in Hastie & Pregibon (1992) (except quasibinomial and quasipoisson).

Examples

```
require(utils) # for str

nf <- gaussian()  # Normal family
str(nf)

gf <- Gamma()
gf
str(gf)
gf$linkinv
gf$variance(-3:4) #-= (.)^2

## quasipoisson. compare with example(glm)
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9)
treatment <- gl(3,3)
d.AD <- data.frame(treatment, outcome, counts)
glm.qD93 <- glm(counts ~ outcome + treatment, family = quasipoisson())
```
### FDist

**The F Distribution**

**Description**

Density, distribution function, quantile function and random generation for the F distribution with df1 and df2 degrees of freedom (and optional non-centrality parameter ncp).

**Usage**

- `df(x, df1, df2, ncp, log = FALSE)`
- `pf(q, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)`
- `qf(p, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)`
- `rf(n, df1, df2, ncp)`
Arguments

- **x, q**: vector of quantiles.
- **p**: vector of probabilities.
- **n**: number of observations. If `length(n) > 1`, the length is taken to be the number required.
- **df1, df2**: degrees of freedom. Inf is allowed.
- **ncp**: non-centrality parameter. If omitted the central F is assumed.
- **log, log.p**: logical; if TRUE, probabilities p are given as log(p).
- **lower.tail**: logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The F distribution with \( df1 = n_1 \) and \( df2 = n_2 \) degrees of freedom has density

\[
f(x) = \frac{\Gamma(n_1/2 + n_2/2)}{\Gamma(n_1/2)\Gamma(n_2/2)} \left( \frac{n_1}{n_2} \right)^{n_1/2} x^{n_1/2-1} \left( 1 + \frac{n_1 x}{n_2} \right)^{-(n_1+n_2)/2}
\]

for \( x > 0 \).

It is the distribution of the ratio of the mean squares of \( n_1 \) and \( n_2 \) independent standard normals, and hence of the ratio of two independent chi-squared variates each divided by its degrees of freedom. Since the ratio of a normal and the root mean-square of \( m \) independent normals has a Student’s \( t_m \) distribution, the square of a \( t_m \) variate has a F distribution on 1 and \( m \) degrees of freedom.

The non-central F distribution is again the ratio of mean squares of independent normals of unit variance, but those in the numerator are allowed to have non-zero means and \( ncp \) is the sum of squares of the means. See `Chisquare` for further details on non-central distributions.

Value

- **df** gives the density, **pf** gives the distribution function **qf** gives the quantile function, and **rf** generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by \( n \) for **rf**, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

Supplying **ncp** = 0 uses the algorithm for the non-central distribution, which is not the same algorithm used if **ncp** is omitted. This is to give consistent behaviour in extreme cases with values of **ncp** very near zero.

The code for non-zero **ncp** is principally intended to be used for moderate values of **ncp**: it will not be highly accurate, especially in the tails, for large values.

Source

For the central case of **df**, computed via a binomial probability, code contributed by Catherine Loader (see `dbinom`); for the non-central case computed via `dbeta`, code contributed by Peter Ruckdeschel.

For **pf**, via `pbeta` (or for large **df2**, via `pchisq`).

For **qf**, via `qchisq` for large **df2**, else via `qbeta`.

Examples

```r
# Equivalence of pt(.nu) with pf(.^2, 1,nu):
x <- seq(0.001, 5, len = 100)
nu <- 4
stopifnot(all.equal(2*pt(x,nu) - 1, pf(x^2, 1,nu)),
  all.equal(2*pt(x, nu, lower=FALSE),
           pf(x^2, 1,nu, lower=FALSE)))

# the density of the square of a t_m is 2*dt(x, m)/(2*x)
all.equal(df(x^2, 1, 5), dt(x, 5)/x)

# Identity: qf(2*p - 1, 1, df)) == qt(p, df)^2) for p >= 1/2
p <- seq(1/2, .99, length = 50); df <- 10
rel.err <- function(x, y) ifelse(x == y, 0, abs(x-y)/mean(abs(c(x,y))))
quantile(rel.err(qf(2*p - 1, df1 = 1, df2 = df), qt(p, df)^2), .90) # ~ 7e-9
```

fft

*Fast Discrete Fourier Transform*

Description

Performs the Fast Fourier Transform of an array.

Usage

```r
fft(z, inverse = FALSE)
mvfft(z, inverse = FALSE)
```

Arguments

- **z**: a real or complex array containing the values to be transformed.
- **inverse**: if TRUE, the unnormalized inverse transform is computed (the inverse has a + in the exponent of e, but here, we do not divide by 1/length(x)).
Value

When \( z \) is a vector, the value computed and returned by `fft` is the unnormalized univariate Fourier transform of the sequence of values in \( z \).

When \( z \) contains an array, `fft` computes and returns the multivariate (spatial) transform. If `inverse` is `TRUE`, the (unnormalized) inverse Fourier transform is returned, i.e., if \( y \leftarrow \text{fft}(z) \), then \( z \) is \( \text{fft}(y, \text{inverse} = \text{TRUE}) / \text{length}(y) \).

By contrast, `mvfft` takes a real or complex matrix as argument, and returns a similar shaped matrix, but with each column replaced by its discrete Fourier transform. This is useful for analyzing vector-valued series.

The FFT is fastest when the length of the series being transformed is highly composite (i.e., has many factors). If this is not the case, the transform may take a long time to compute and will use a large amount of memory.

**filter**

 Linear Filtering on a Time Series

Description

Applies linear filtering to a univariate time series or to each series separately of a multivariate time series.

Usage

```r
filter(x, filter, method = c(”convolution”, ”recursive”), sides = 2, circular = FALSE, init)
```
Arguments

- **x**: a univariate or multivariate time series.
- **filter**: a vector of filter coefficients in reverse time order (as for AR or MA coefficients).
- **method**: Either "convolution" or "recursive" (and can be abbreviated). If "convolution" a moving average is used; if "recursive" an autoregression is used.
- **sides**: for convolution filters only. If sides = 1 the filter coefficients are for past values only; if sides = 2 they are centred around lag 0. In this case the length of the filter should be odd, but if it is even, more of the filter is forward in time than backward.
- **circular**: for convolution filters only. If TRUE, wrap the filter around the ends of the series, otherwise assume external values are missing (NA).
- **init**: for recursive filters only. Specifies the initial values of the time series just prior to the start value, in reverse time order. The default is a set of zeros.

Details

Missing values are allowed in x but not in filter (where they would lead to missing values everywhere in the output).

Note that there is an implied coefficient 1 at lag 0 in the recursive filter, which gives

\[ y_i = x_i + f_1 y_{i-1} + \cdots + f_p y_{i-p} \]

No check is made to see if recursive filter is invertible: the output may diverge if it is not.

The convolution filter is

\[ y_i = f_1 x_{i+o} + \cdots + f_p x_{i+o-(p-1)} \]

where o is the offset: see sides for how it is determined.

Value

A time series object.

Note

convolve, type = "filter") uses the FFT for computations and so may be faster for long filters on univariate series, but it does not return a time series (and so the time alignment is unclear), nor does it handle missing values. filter is faster for a filter of length 100 on a series of length 1000, for example.

See Also

convolve, arima.sim

Examples

```r
x <- 1:100
filter(x, rep(1, 3))
filter(x, rep(1, 3), sides = 1)
filter(x, rep(1, 3), sides = 1, circular = TRUE)
filter(presidents, rep(1, 3))
```
Description

Performs Fisher’s exact test for testing the null of independence of rows and columns in a contingency table with fixed marginals.

Usage

```r
fisher.test(x, y = NULL, workspace = 200000, hybrid = FALSE,
            control = list(), or = 1, alternative = "two.sided",
            conf.int = TRUE, conf.level = 0.95,
            simulate.p.value = FALSE, B = 2000)
```

Arguments

- `x`: either a two-dimensional contingency table in matrix form, or a factor object.
- `y`: a factor object; ignored if `x` is a matrix.
- `workspace`: an integer specifying the size of the workspace used in the network algorithm. In units of 4 bytes. Only used for non-simulated p-values larger than $2 \times 2$ tables.
- `hybrid`: a logical. Only used for larger than $2 \times 2$ tables, in which cases it indicates whether the exact probabilities (default) or a hybrid approximation thereof should be computed. See ‘Details’.
- `control`: a list with named components for low level algorithm control. At present the only one used is "mult", a positive integer $\geq 2$ with default 30 used only for larger than $2 \times 2$ tables. This says how many times as much space should be allocated to paths as to keys: see file ‘fexact.c’ in the sources of this package.
- `or`: the hypothesized odds ratio. Only used in the $2 \times 2$ case.
- `alternative`: indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the $2 \times 2$ case.
- `conf.int`: logical indicating if a confidence interval for the odds ratio in a $2 \times 2$ table should be computed (and returned).
- `conf.level`: confidence level for the returned confidence interval. Only used in the $2 \times 2$ case and if `conf.int = TRUE`.
- `simulate.p.value`: a logical indicating whether to compute p-values by Monte Carlo simulation, in larger than $2 \times 2$ tables.
- `B`: an integer specifying the number of replicates used in the Monte Carlo test.

Details

If `x` is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both `x` and `y` must be vectors of the same length. Incomplete cases are removed, the vectors are coerced into factor objects, and the contingency table is computed from these.
For $2 \times 2$ cases, p-values are obtained directly using the (central or non-central) hypergeometric distribution. Otherwise, computations are based on a C version of the FORTRAN subroutine FEXACT which implements the network developed by Mehta and Patel (1986) and improved by Clarkson, Fan and Joe (1993). The FORTRAN code can be obtained from [http://www.netlib.org/toms/643](http://www.netlib.org/toms/643). Note this fails (with an error message) when the entries of the table are too large. (It transposes the table if necessary so it has no more rows than columns. One constraint is that the product of the row marginals be less than $2^{31} - 1$.)

For $2 \times 2$ tables, the null of conditional independence is equivalent to the hypothesis that the odds ratio equals one. 'Exact' inference can be based on observing that in general, given all marginal totals fixed, the first element of the contingency table has a non-central hypergeometric distribution with non-centrality parameter given by the odds ratio (Fisher, 1935). The alternative for a one-sided test is based on the odds ratio, so alternative = "greater" is a test of the odds ratio being bigger than or.

Two-sided tests are based on the probabilities of the tables, and take as 'more extreme' all tables with probabilities less than or equal to that of the observed table, the p-value being the sum of such probabilities.

For larger than $2 \times 2$ tables and hybrid = TRUE, asymptotic chi-squared probabilities are only used if the 'Cochran conditions' are satisfied, that is if no cell has count zero, and more than 80% of the cells have counts at least 5; otherwise the exact calculation is used.

Simulation is done conditional on the row and column marginals, and works only if the marginals are strictly positive. (A C translation of the algorithm of Patefield (1981) is used.)

**Value**

A list with class "htest" containing the following components:

- `p.value`: the p-value of the test.
- `conf.int`: a confidence interval for the odds ratio. Only present in the $2 \times 2$ case and if argument `conf.int` = TRUE.
- `estimate`: an estimate of the odds ratio. Note that the conditional Maximum Likelihood Estimate (MLE) rather than the unconditional MLE (the sample odds ratio) is used. Only present in the $2 \times 2$ case.
- `null.value`: the odds ratio under the null, or. Only present in the $2 \times 2$ case.
- `alternative`: a character string describing the alternative hypothesis.
- `method`: the character string "Fisher's Exact Test for Count Data".
- `data.name`: a character string giving the names of the data.

fisher.test(Job, simulate.p.value = TRUE, B = 1e5)
```

```
```
Description

fitted is a generic function which extracts fitted values from objects returned by modeling functions. fitted.values is an alias for it.

All object classes which are returned by model fitting functions should provide a fitted method. (Note that the generic is fitted and not fitted.values.)

Methods can make use of napredict methods to compensate for the omission of missing values. The default and nls methods do.

Usage

fitted(object, ...)
fitted.values(object, ...)

Arguments

object an object for which the extraction of model fitted values is meaningful.
...
other arguments.

Value

Fitted values extracted from the object object.

References

See Also

coefficients, glm, lm, residuals.

fivenum Tukey Five-Number Summaries

Description

Returns Tukey’s five number summary (minimum, lower-hinge, median, upper-hinge, maximum) for the input data.

Usage

fivenum(x, na.rm = TRUE)

Arguments

x numeric, maybe including NAs and ±Inf.
na.rm logical; if TRUE, all NA and NaNs are dropped, before the statistics are computed.

Value

A numeric vector of length 5 containing the summary information. See boxplot.stats for more details.
See Also
IQR, boxplot.stats, median, quantile, range.

Examples
fivenum(c(rnorm(100), -1:1/0))
The Fligner-Killeen (median) test has been determined in a simulation study as one of the many
tests for homogeneity of variances which is most robust against departures from normality, see
Conover, Johnson & Johnson (1981). It is a $k$-sample simple linear rank which uses the ranks of the
absolute values of the centered samples and weights $a(i) = \text{qnorm}(1+i/(n+1))/2$. The version
implemented here uses median centering in each of the samples (F-K:med $X^2$ in the reference).

**Value**

A list of class "htest" containing the following components:

- **statistic** the Fligner-Killeen:med $X^2$ test statistic.
- **parameter** the degrees of freedom of the approximate chi-squared distribution of the test
  statistic.
- **p.value** the p-value of the test.
- **method** the character string "Fligner-Killeen test of homogeneity of variances".
- **data.name** a character string giving the names of the data.

**References**

William J. Conover, Mark E. Johnson and Myrle M. Johnson (1981). A comparative study of
tests for homogeneity of variances, with applications to the outer continental shelf bidding data.

**See Also**

- ansari.test and mood.test for rank-based two-sample test for a difference in scale parameters;
- var.test and bartlett.test for parametric tests for the homogeneity of variances.

**Examples**

```r
require(graphics)

plot(count ~ spray, data = InsectSprays)
fligner.test(InsectSprays$count, InsectSprays$spray)
fligner.test(count ~ spray, data = InsectSprays)
## Compare this to bartlett.test()
```

---

**formula**

*Model Formulae*

**Description**

The generic function `formula` and its specific methods provide a way of extracting formulae which
have been included in other objects.

`as.formula` is almost identical, additionally preserving attributes when object already inherits
from "formula".
Usage

```
formula(x, ...) 
as.formula(object, env = parent.frame())
```

### S3 method for class 'formula'

```
print(x, showEnv = !identical(e, .GlobalEnv), ...)
```

**Arguments**

- `x`, `object` R object.
- `...` further arguments passed to or from other methods.
- `env` the environment to associate with the result, if not already a formula.
- `showEnv` logical indicating if the environment should be printed as well.

**Details**

The models fit by, e.g., the `lm` and `glm` functions are specified in a compact symbolic form. The ~ operator is basic in the formation of such models. An expression of the form `y ~ model` is interpreted as a specification that the response `y` is modelled by a linear predictor specified symbolically by `model`. Such a model consists of a series of terms separated by `+` operators. The terms themselves consist of variable and factor names separated by `:` operators. Such a term is interpreted as the interaction of all the variables and factors appearing in the term.

In addition to `+` and `:`, a number of other operators are useful in model formulae. The `*` operator denotes factor crossing: `a*b` interpreted as `a+b+a:b`. The `%in%` operator indicates crossing to the specified degree. For example `(a+b+c)^2` is identical to `(a+b+c)*(a+b+c)` which in turn expands to a formula containing the main effects for `a`, `b`, and `c` together with their second-order interactions. The `%in%` operator indicates that the terms on its left are nested within those on the right. For example `a + b %in% a` expands to the formula `a + a:b`. The ~ operator removes the specified terms, so that `(a+b+c)^2 - a:b` is identical to `a + b + c + b:c + a:c`. It can also used to remove the intercept term: when fitting a linear model `y ~ x - 1` specifies a line through the origin. A model with no intercept can be also specified as `y ~ x + 0` or `y ~ 0 + x`.

While formulae usually involve just variable and factor names, they can also involve arithmetic expressions. The formula `log(y) ~ a + log(x)` is quite legal. When such arithmetic expressions involve operators which are also used symbolically in model formulae, there can be confusion between arithmetic and symbolic operator use.

To avoid this confusion, the function `I()` can be used to bracket those portions of a model formula where the operators are used in their arithmetic sense. For example, in the formula `y ~ a + I(b+c)`, the term `b+c` is to be interpreted as the sum of `b` and `c`.

Variable names can be quoted by backticks `like this` in formulae, although there is no guarantee that all code using formulae will accept such non-syntactic names.

Most model-fitting functions accept formulae with right-hand-side including the function `offset` to indicate terms with a fixed coefficient of one. Some functions accept other ‘specials’ such as `strata` or `cluster` (see the specials argument of `terms.formula`).

There are two special interpretations of ~ in a formula. The usual one is in the context of a data argument of model fitting functions and means ‘all columns not otherwise in the formula’: see `terms.formula`. In the context of `update.formula`, `only`, it means ‘what was previously in this part of the formula’.

When `formula` is called on a fitted model object, either a specific method is used (such as that for class "nls") or the default method. The default first looks for a "formula" component of the object.
(and evaluates it), then a "terms" component, then a formula parameter of the call (and evaluates its value) and finally a "formula" attribute.

There is a formula method for data frames. If there is only one column this forms the RHS with an empty LHS. For more columns, the first column is the LHS of the formula and the remaining columns separated by + form the RHS.

Value

All the functions above produce an object of class "formula" which contains a symbolic model formula.

Environments

A formula object has an associated environment, and this environment (rather than the parent environment) is used by model.frame to evaluate variables that are not found in the supplied data argument.

Formulas created with the ~ operator use the environment in which they were created. Formulas created with as.formula will use the env argument for their environment.

environment(fo)
environment(as.formula("y ~ x"))
environment(as.formula("y ~ x", env = new.env()))

## Create a formula for a model with a large number of variables:
xnam <- paste0("x", 1:25)
(fmla <- as.formula(paste("y ~", paste(xnam, collapse = "+")))))
**formul.nls**

*Extract Model Formula from nls Object*

**Description**

Returns the model used to fit object.

**Usage**

```r
## S3 method for class 'nls'
formula(x, ...)
```

**Arguments**

- `x` an object inheriting from class "nls", representing a nonlinear least squares fit.
- `...` further arguments passed to or from other methods.

**Value**

a formula representing the model used to obtain object.

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

`nls, formula`

**Examples**

```r
fm1 <- nls(circumference ~ A/(1+exp((B-age)/C)), Orange,
           start = list(A = 160, B = 700, C = 350))
formula(fm1)
```

---

**friedman.test**

*Friedman Rank Sum Test*

**Description**

Performs a Friedman rank sum test with unreplicated blocked data.

**Usage**

```r
friedman.test(y, ...)
```

**Examples**

```r
## Default S3 method:
friedman.test(y, groups, blocks, ...)

## S3 method for class 'formula'
friedman.test(formula, data, subset, na.action, ...)
```
Arguments

- **y**: either a numeric vector of data values, or a data matrix.
- **groups**: a vector giving the group for the corresponding elements of *y* if this is a vector; ignored if *y* is a matrix. If not a factor object, it is coerced to one.
- **blocks**: a vector giving the block for the corresponding elements of *y* if this is a vector; ignored if *y* is a matrix. If not a factor object, it is coerced to one.
- **formula**: a formula of the form *a ~ b | c*, where *a*, *b* and *c* give the data values and corresponding groups and blocks, respectively.
- **data**: an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- **...**: further arguments to be passed to or from methods.

Details

`friedman.test` can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in *y* for each combination of levels of *groups* and *blocks*) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of *blocks*, the location parameter of *y* is the same in each of the *groups*.

If *y* is a matrix, *groups* and *blocks* are obtained from the column and row indices, respectively. NAs are not allowed in *groups* or *blocks*; if *y* contains NAs, corresponding blocks are removed.

Value

A list with class "htest" containing the following components:

- **statistic**: the value of Friedman's chi-squared statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- **p.value**: the p-value of the test.
- **method**: the character string "Friedman rank sum test".
- **data.name**: a character string giving the names of the data.

ftable  

**Flat Contingency Tables**

Description

Create ‘flat’ contingency tables.
Usage

ftable(x, ...)

## Default S3 method:
ftable(..., exclude = c(NA, NaN), row.vars = NULL,
        col.vars = NULL)

Arguments

x, ...  R objects which can be interpreted as factors (including character strings), or a
        list (or data frame) whose components can be so interpreted, or a contingency
table object of class "table" or "ftable".
exclude  values to use in the exclude argument of factor when interpreting non-factor
        objects.
row.vars  a vector of integers giving the numbers of the variables, or a character vector
giving the names of the variables to be used for the rows of the flat contingency
table.
col.vars  a vector of integers giving the numbers of the variables, or a character vector giv-
        ing the names of the variables to be used for the columns of the flat contingency
table.

Details

ftable creates ‘flat’ contingency tables. Similar to the usual contingency tables, these contain the
counts of each combination of the levels of the variables (factors) involved. This information is
then re-arranged as a matrix whose rows and columns correspond to unique combinations of the
levels of the row and column variables (as specified by row.vars and col.vars, respectively). The
combinations are created by looping over the variables in reverse order (so that the levels of the
left-most variable vary the slowest). Displaying a contingency table in this flat matrix form (via
print.ftable, the print method for objects of class "ftable") is often preferable to showing it as
a higher-dimensional array.

ftable is a generic function. Its default method, ftable.default, first creates a contingency table
in array form from all arguments except row.vars and col.vars. If the first argument is of class
"table", it represents a contingency table and is used as is; if it is a flat table of class "ftable", the
information it contains is converted to the usual array representation using as.ftable. Otherwise,
the arguments should be R objects which can be interpreted as factors (including character strings),
or a list (or data frame) whose components can be so interpreted, which are cross-tabulated using
table. Then, the arguments row.vars and col.vars are used to collapse the contingency table
into flat form. If neither of these two is given, the last variable is used for the columns. If both are
given and their union is a proper subset of all variables involved, the other variables are summed
out.

When the arguments are R expressions interpreted as factors, additional arguments will be passed
to table to control how the variable names are displayed; see the last example below.
Function ftable.formula provides a formula method for creating flat contingency tables.

There are methods for as.table, as.matrix and as.data.frame.

Value

ftable returns an object of class "ftable", which is a matrix with counts of each combination of
the levels of variables with information on the names and levels of the (row and columns) variables
stored as attributes "row.vars" and "col.vars".
ftable.formula

See Also

ftable.formula for the formula interface (which allows a data = . argument); read.ftable for information on reading, writing and coercing flat contingency tables; table for ordinary cross-tabulation; xtabs for formula-based cross-tabulation.

Examples

## Start with a contingency table.
ftable(Titanic, row.vars = 1:3)
ftable(Titanic, row.vars = 1:2, col.vars = "Survived")
ftable(Titanic, row.vars = 2:1, col.vars = "Survived")

## Start with a data frame.
x <- ftable(mtcars[,c("cyl", "vs", "am", "gear")])
x
ftable(x, row.vars = c(2, 4))

## Start with expressions, use table()’s ”dnn” to change labels
ftable(mtcars$cyl, mtcars$vs, mtcars$am, mtcars$gear, row.vars = c(2, 4),
       dnn = c("Cylinders", "V/S", "Transmission", "Gears"))

---

ftable.formula  Formula Notation for Flat Contingency Tables

Description

Produce or manipulate a flat contingency table using formula notation.

Usage

## S3 method for class 'formula'
ftable(formula, data = NULL, subset, na.action, ...)

Arguments

formula
  a formula object with both left and right hand sides specifying the column and row variables of the flat table.

data
  a data frame, list or environment (or similar: see model.frame) containing the variables to be cross-tabulated, or a contingency table (see below).

subset
  an optional vector specifying a subset of observations to be used. Ignored if data is a contingency table.

na.action
  a function which indicates what should happen when the data contain NAs. Ignored if data is a contingency table.

...
  further arguments to the default ftable method may also be passed as arguments, see ftable.default.
Details

This is a method of the generic function `ftable`.

The left and right hand side of `formula` specify the column and row variables, respectively, of the flat contingency table to be created. Only the `+` operator is allowed for combining the variables. A `.` may be used once in the formula to indicate inclusion of all the remaining variables.

If `data` is an object of class "" or an array with more than 2 dimensions, it is taken as a contingency table, and hence all entries should be nonnegative. Otherwise, if it is not a flat contingency table (i.e., an object of class "ftable"), it should be a data frame or matrix, list or environment containing the variables to be cross-tabulated. In this case, `na.action` is applied to the data to handle missing values, and, after possibly selecting a subset of the data as specified by the `subset` argument, a contingency table is computed from the variables.

The contingency table is then collapsed to a flat table, according to the row and column variables specified by `formula`.

Value

A flat contingency table which contains the counts of each combination of the levels of the variables, collapsed into a matrix for suitably displaying the counts.

`ftable`, `ftable.default`, `table`.

Examples

```r
Titanic
x <- ftable(Survived ~ ., data = Titanic)
x
ftable(Sex ~ Class + Age, data = x)
```

### GammaDist

**The Gamma Distribution**

Description

Density, distribution function, quantile function and random generation for the Gamma distribution with parameters `shape` and `scale`.

Usage

```r
dgamma(x, shape = 1, rate = 1, scale = 1/rate, log = FALSE)
pgamma(q, shape = 1, rate = 1, scale = 1/rate, lower.tail = TRUE, log.p = FALSE)
qgamma(p, shape = 1, rate = 1, scale = 1/rate, lower.tail = TRUE, log.p = FALSE)
rgamma(n, shape = 1, rate = 1, scale = 1/rate)
```
**Arguments**

- `x, q`: vector of quantiles.
- `p`: vector of probabilities.
- `n`: number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `rate`: an alternative way to specify the scale.
- `shape, scale`: shape and scale parameters. Must be positive, scale strictly.
- `log, log.p`: logical; if TRUE, probabilities/densities `p` are returned as `log(p)`.
- `lower.tail`: logical; if TRUE (default), probabilities are `P[X ≤ x]`, otherwise, `P[X > x]`.

**Details**

If `scale` is omitted, it assumes the default value of 1.

The Gamma distribution with parameters `shape = α` and `scale = σ` has density

\[ f(x) = \frac{1}{\sigma^\alpha \Gamma(\alpha)} x^{\alpha-1} e^{-x/\sigma} \]

for \( x ≥ 0, \alpha > 0 \) and \( \sigma > 0 \). (Here \( \Gamma(\alpha) \) is the function implemented by R’s `gamma()` and defined in its help. Note that \( \alpha = 0 \) corresponds to the trivial distribution with all mass at point 0.)

The mean and variance are \( E(X) = \alpha \sigma \) and \( Var(X) = \alpha \sigma^2 \).

The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is

\[-\text{pgamma}(t, \ldots, \text{lower} = \text{FALSE}, \log = \text{TRUE})\]

Note that for smallish values of shape (and moderate scale) a large parts of the mass of the Gamma distribution is on values of `x` so near zero that they will be represented as zero in computer arithmetic. So `rgamma` may well return values which will be represented as zero. (This will also happen for very large values of `scale` since the actual generation is done for `scale = 1`.)

**Value**

dgamma gives the density, pgamma gives the distribution function, qgamma gives the quantile function, and rgamma generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by `n` for `rgamma`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

The S (Becker et al 1988) parametrization was via `shape` and `rate`: S had no `scale` parameter. In R 2.x.y `scale` took precedence over `rate`, but now it is an error to supply both.

`pgamma` is closely related to the incomplete gamma function. As defined by Abramowitz and Stegun 6.5.1 (and by ‘Numerical Recipes’) this is

\[ P(\alpha, x) = \frac{1}{\Gamma(\alpha)} \int_0^x t^{\alpha-1} e^{-t} dt \]
\( P(a, x) \) is \( \text{pgamma}(x, a) \). Other authors (for example Karl Pearson in his 1922 tables) omit the normalizing factor, defining the incomplete gamma function \( \gamma(a, x) \) as \( \gamma(a, x) = \int_0^x t^{a-1}e^{-t}dt \), i.e., \( \text{pgamma}(x, a) \times \text{gamma}(a) \). Yet other use the ‘upper’ incomplete gamma function,

\[
\Gamma(a, x) = \int_x^\infty t^{a-1}e^{-t}dt,
\]

which can be computed by \( \text{pgamma}(x, a, \text{lower} = \text{FALSE}) \times \text{gamma}(a) \).

Note however that \( \text{pgamma}(x, a, \ldots) \) currently requires \( a > 0 \), whereas the incomplete gamma function is also defined for negative \( a \). In that case, you can use \( \text{gamma}_\text{inc}(a, x) \) (for \( \Gamma(a, x) \)) from package \text{gsl}.

See also \url{http://en.wikipedia.org/wiki/Incomplete_gamma_function}, or \url{http://dlmf.nist.gov/8.2#i}.

Source

dgamma is computed via the Poisson density, using code contributed by Catherine Loader (see \text{dbinom}).

pgamma uses an unpublished (and not otherwise documented) algorithm ‘mainly by Morten Welinder’.

qgamma is based on a C translation of

plus a final Newton step to improve the approximation.

rgamma for shape \( \geq 1 \) uses

and for \( 0 < \text{shape} < 1 \) uses

gamma for the gamma function.

\text{Distributions} for other standard distributions, including \text{dbeta} for the Beta distribution and \text{dchisq} for the chi-squared distribution which is a special case of the Gamma distribution.
Examples

```r
-log(dgamma(1:4, shape = 1))
p <- (1:9)/10
pgamma(qgamma(p, shape = 2), shape = 2)
1 - 1/exp(qgamma(p, shape = 1))
```

# even for shape = 0.001 about half the mass is on numbers
# that cannot be represented accurately (and most of those as zero)
pgamma(.Machine$double.xmin, 0.001)
pgamma(5e-324, 0.001)  # on most machines 5e-324 is the smallest
  # representable non-zero number
table(rgamma(1e4, 0.001) == 0)/1e4

---

### Geometric

#### The Geometric Distribution

**Description**

Density, distribution function, quantile function and random generation for the geometric distribution with parameter `prob`.

**Usage**

```r
dgeom(x, prob, log = FALSE)
pgeom(q, prob, lower.tail = TRUE, log.p = FALSE)
qgeom(p, prob, lower.tail = TRUE, log.p = FALSE)
rgeom(n, prob)
```

**Arguments**

- `x, q` vector of quantiles representing the number of failures in a sequence of Bernoulli trials before success occurs.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `prob` probability of success in each trial. `0 < prob <= 1`.
- `log, log.p` logical; if `TRUE`, probabilities `p` are given as `log(p)`.
- `lower.tail` logical; if `TRUE` (default), probabilities are `P[X <= x]`, otherwise, `P[X > x]`.

**Details**

The geometric distribution with `prob = p` has density

\[ p(x) = p(1 - p)^x \]

for \( x = 0, 1, 2, \ldots, 0 < p \leq 1 \).

If an element of `x` is not integer, the result of `dgeom` is zero, with a warning.

The quantile is defined as the smallest value `x` such that \( F(x) \geq p \), where \( F \) is the distribution function.
Value

dgeom gives the density, pgeom gives the distribution function, qgeom gives the quantile function, and rgeom generates random deviates.
Invalid prob will result in return value NaN, with a warning.
The length of the result is determined by n for rgeom, and is the maximum of the lengths of the numerical arguments for the other functions.
The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Source

dgeom computes via dbinom, using code contributed by Catherine Loader (see dbinom).
pgeom and qgeom are based on the closed-form formulae.
rgeom uses the derivation as an exponential mixture of Poissons, see

See Also

Distributions for other standard distributions, including dnbinom for the negative binomial which generalizes the geometric distribution.

Examples

```r
ggeom(1:9)/10, prob = .2)  
Ni <- rgeom(20, prob = 1/4); table(factor(Ni, 0:max(Ni)))
```

---

**getInitial**

*Get Initial Parameter Estimates*

Description

This function evaluates initial parameter estimates for a nonlinear regression model. If data is a parameterized data frame or pframe object, its parameters attribute is returned. Otherwise the object is examined to see if it contains a call to a selfStart object whose initial attribute can be evaluated.

Usage

```r
getInitial(object, data, ...)
```

Arguments

- **object** a formula or a selfStart model that defines a nonlinear regression model
- **data** a data frame in which the expressions in the formula or arguments to the selfStart model can be evaluated
- **...** optional additional arguments
glm

Value

A named numeric vector or list of starting estimates for the parameters. The construction of many selfStart models is such that these "starting" estimates are, in fact, the converged parameter estimates.

Author(s)

José Pinheiro and Douglas Bates

See Also

nls, selfStart, selfStart.default, selfStart.formula

Examples

purTrt <- Puromycin[ Puromycin$state == "treated", ]
print(getInitial( rate ~ SSmicmen( conc, Vm, K ), PurTrt ), digits = 3)

Description

glm is used to fit generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution.

Usage

glm(formula, family = gaussian, data, weights, subset,
    na.action, start = NULL, etastart, mustart, offset,
    control = list(...), model = TRUE, method = "glm.fit",
    x = FALSE, y = TRUE, contrasts = NULL, ...)

glm.fit(x, y, weights = rep(1, nobs),
    start = NULL, etastart = NULL, mustart = NULL,
    offset = rep(0, nobs), family = gaussian(),
    control = list(), intercept = TRUE)

## S3 method for class 'glm'
weights(object, type = c("prior", "working"), ...)

Arguments

formula an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under 'Details'.

family a description of the error distribution and link function to be used in the model. This can be a character string naming a family function, a family function or the result of a call to a family function. (See family for details of family functions.)
glm

data
an optional data frame, list or environment (or object coercible by
as.data.frame to a data frame) containing the variables in the model. If not
found in data, the variables are taken from environment(formula), typically
the environment from which glm is called.

weights
an optional vector of 'prior weights' to be used in the fitting process. Should be
NULL or a numeric vector.

subset
an optional vector specifying a subset of observations to be used in the fitting
process.

na.action
a function which indicates what should happen when the data contain NAs. The
default is set by the na.action setting of options, and is na.fail if that is
unset. The 'factory-fresh' default is na.omit. Another possible value is NULL,
no action. Value na.exclude can be useful.

start
starting values for the parameters in the linear predictor.

etastart
starting values for the linear predictor.

mustart
starting values for the vector of means.

offset
this can be used to specify an a priori known component to be included in the
linear predictor during fitting. This should be NULL or a numeric vector of length
equal to the number of cases. One or more offset terms can be included in the
formula instead or as well, and if more than one is specified their sum is used.
See model.offset.

control
a list of parameters for controlling the fitting process. For glm.fit this is passed
to glm.control.

model
a logical value indicating whether model.frame should be included as a com-
ponent of the returned value.

method
the method to be used in fitting the model. The default method "glm.fit" uses
iteratively reweighted least squares (IWLS): the alternative "model.frame" re-
turns the model frame and does no fitting.

User-supplied fitting functions can be supplied either as a function or a character
string naming a function, with a function which takes the same arguments as
glm.fit. If specified as a character string it is looked up from within the stats
namespace.

x, y
For glm: logical values indicating whether the response vector and model matrix
used in the fitting process should be returned as components of the returned
value.

For glm.fit: x is a design matrix of dimension n * p, and y is a vector of
observations of length n.

contrasts
an optional list. See the contrasts.arg of model.matrix.default.

intercept
logical. Should an intercept be included in the null model?

object
an object inheriting from class "glm".

type
character, partial matching allowed. Type of weights to extract from the fitted
model object.

... For glm: arguments to be used to form the default control argument if it is not
supplied directly.

For weights: further arguments passed to or from other methods.
Details

A typical predictor has the form \( \text{response} \sim \text{terms} \) where \( \text{response} \) is the (numeric) response vector and \( \text{terms} \) is a series of terms which specifies a linear predictor for \( \text{response} \). For binomial and quasibinomial families the response can also be specified as a \( \text{factor} \) (when the first level denotes failure and all others success) or as a two-column matrix with the columns giving the numbers of successes and failures. A terms specification of the form \( \text{first} + \text{second} \) indicates all the terms in \( \text{first} \) together with all the terms in \( \text{second} \) with any duplicates removed.

A specification of the form \( \text{first}:\text{second} \) indicates the set of terms obtained by taking the interactions of all terms in \( \text{first} \) with all terms in \( \text{second} \). The specification \( \text{first} \times \text{second} \) indicates the \emph{cross} of \( \text{first} \) and \( \text{second} \). This is the same as \( \text{first} + \text{second} + \text{first}:\text{second} \).

The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a \text{terms} object as the formula.

Non-NULL weights can be used to indicate that different observations have different dispersions (with the values in weights being inversely proportional to the dispersions); or equivalently, when the elements of weights are positive integers \( w_i \), that each response \( y_i \) is the mean of \( w_i \) unit-weight observations. For a binomial GLM prior weights are used to give the number of trials when the response is the proportion of successes: they would rarely be used for a Poisson GLM.

glm.fit is the workhorse function: it is not normally called directly but can be more efficient where the response vector and design matrix have already been calculated.

If more than one of etastart, start and mustart is specified, the first in the list will be used. It is often advisable to supply starting values for a \text{quasi} family, and also for families with unusual links such as gaussian("log").

All of weights, subset, offset, etastart and mustart are evaluated in the same way as variables in formula, that is first in data and then in the environment of formula.

For the background to warning messages about ‘fitted probabilities numerically 0 or 1 occurred’ for binomial GLMs, see Venables & Ripley (2002, pp. 197–8).

Value

\text{glm} returns an object of class inheriting from "\text{glm}" which inherits from the class "\text{lm}". See later in this section. If a non-standard method is used, the object will also inherit from the class (if any) returned by that function.

The function \text{summary} (i.e., \text{summary.glm}) can be used to obtain or print a summary of the results and the function \text{anova} (i.e., \text{anova.glm}) to produce an analysis of variance table.

The generic accessor functions \text{coefficients}, \text{effects}, \text{fitted.values} and \text{residuals} can be used to extract various useful features of the value returned by \text{glm}.

\text{weights} extracts a vector of weights, one for each case in the fit (after subsetting and na.action).

An object of class "\text{glm}" is a list containing at least the following components:

- \text{coefficients} a named vector of coefficients
- \text{residuals} the \emph{working} residuals, that is the residuals in the final iteration of the IWLS fit. Since cases with zero weights are omitted, their working residuals are \text{NA}.
- \text{fitted.values} the fitted mean values, obtained by transforming the linear predictors by the inverse of the link function.
- \text{rank} the numeric rank of the fitted linear model.
- \text{family} the \text{family} object used.
- \text{linear.predictors} the linear fit on link scale.
deviance
up to a constant, minus twice the maximized log-likelihood. Where sensible, the
constant is chosen so that a saturated model has deviance zero.

aic
A version of Akaike’s An Information Criterion, minus twice the maximized
log-likelihood plus twice the number of parameters, computed by the aic com-
ponent of the family. For binomial and Poisson families the dispersion is fixed
at one and the number of parameters is the number of coefficients. For gauss-
ian, Gamma and inverse gaussian families the dispersion is estimated from the
residual deviance, and the number of parameters is the number of coefficients
plus one. For a gaussian family the MLE of the dispersion is used so this is a
valid value of AIC, but for Gamma and inverse gaussian families it is not. For
families fitted by quasi-likelihood the value is NA.

null.deviance
The deviance for the null model, comparable with deviance. The null model
will include the offset, and an intercept if there is one in the model. Note that
this will be incorrect if the link function depends on the data other than through
the fitted mean: specify a zero offset to force a correct calculation.

iter
the number of iterations of IWLS used.

weights
the working weights, that is the weights in the final iteration of the IWLS fit.
prior.weights
the weights initially supplied, a vector of 1s if none were.
df.residual
the residual degrees of freedom.
df.null
the residual degrees of freedom for the null model.
y
if requested (the default) the y vector used. (It is a vector even for a binomial
model.)
x
if requested, the model matrix.
model
if requested (the default), the model frame.

converged
logical. Was the IWLS algorithm judged to have converged?

boundary
logical. Is the fitted value on the boundary of the attainable values?
call
the matched call.

formula
the formula supplied.
terms
the terms object used.
data
the data argument.

offset
the offset vector used.

control
the value of the control argument used.

method
the name of the fitter function used, currently always "glm.fit".

contrasts
(where relevant) the contrasts used.

xlevels
(where relevant) a record of the levels of the factors used in fitting.

na.action
(where relevant) information returned by model.frame on the special handling
of NAs.

In addition, non-empty fits will have components qr, R and effects relating to the final weighted
linear fit.

Objects of class "glm" are normally of class c("glm", "lm"), that is inherit from class
"lm", and well-designed methods for class "lm" will be applied to the weighted linear model at the
final iteration of IWLS. However, care is needed, as extractor functions for class "lm" such as
residuals and weights do not just pick out the component of the fit with the same name.

If a binomial glm model was specified by giving a two-column response, the weights returned
by prior.weights are the total numbers of cases (factored by the supplied case weights) and the
component y of the result is the proportion of successes.
Fitting functions

The argument method serves two purposes. One is to allow the model frame to be recreated with no fitting. The other is to allow the default fitting function glm.fit to be replaced by a function which takes the same arguments and uses a different fitting algorithm. If glm.fit is supplied as a character string it is used to search for a function of that name, starting in the stats namespace.

The class of the object return by the fitter (if any) will be prepended to the class returned by glm.

Author(s)

The original R implementation of glm was written by Simon Davies working for Ross Ihaka at the University of Auckland, but has since been extensively re-written by members of the R Core team.

The design was inspired by the S function of the same name described in Hastie & Pregibon (1992).

### glm.control

**Auxiliary for Controlling GLM Fitting**

#### Description

Auxiliary function for `glm` fitting. Typically only used internally by `glm.fit`, but may be used to construct a control argument to either function.

#### Usage

```r
glm.control(epsilon = 1e-8, maxit = 25, trace = FALSE)
```

#### Arguments

- **epsilon**: positive convergence tolerance \(\epsilon\); the iterations converge when \(|\text{dev} - \text{dev}_{\text{old}}|/(|\text{dev}| + 0.1) < \epsilon\).
- **maxit**: integer giving the maximal number of IWLS iterations.
- **trace**: logical indicating if output should be produced for each iteration.

#### Details

The `control` argument of `glm` is by default passed to the control argument of `glm.fit`, which uses its elements as arguments to `glm.control`: the latter provides defaults and sanity checking. If `epsilon` is small (less than \(10^{-10}\)) it is also used as the tolerance for the detection of collinearity in the least squares solution.

When `trace` is true, calls to `cat` produce the output for each IWLS iteration. Hence, `options(digits = *)` can be used to increase the precision, see the example.

#### Value

A list with components named as the arguments.

#### References

See Also
glm.fit, the fitting procedure used by glm.

Examples

```r
### A variation on  example(glm):
## Annette Dobson's example ...
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9)
treatment <- gl(3,3)
oo <- options(digits = 12) # to see more when tracing :
glm.D93X <- glm(counts ~ outcome + treatment, family = poisson(),
                trace = TRUE, epsilon = 1e-14)
options(o0)
coef(glm.D93X) # the last two are closer to 0 than in glm's  glm.D93
```

## glm.summaries

### Accessing Generalized Linear Model Fits

#### Description

These functions are all methods for class glm or summary.glm objects.

#### Usage

```r
## S3 method for class 'glm'
family(object, ...)

## S3 method for class 'glm'
residuals(object, type = c("deviance", "pearson", "working",
                        "response", "partial"), ...)
```

#### Arguments

- `object` an object of class glm, typically the result of a call to glm.
- `type` the type of residuals which should be returned. The alternatives are: "deviance" (default), "pearson", "working", "response", and "partial".
- `...` further arguments passed to or from other methods.

#### Details

The references define the types of residuals: Davison & Snell is a good reference for the usages of each.

The partial residuals are a matrix of working residuals, with each column formed by omitting a term from the model.

How residuals treats cases with missing values in the original fit is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear, with residual value NA. See also `naresid`.

For fits done with `y = FALSE` the response values are computed from other components.
References

influence.measures for deletion diagnostics, including standardized (rstandard) and studentized (rstudent) residuals.

hclust

Hierarchical Clustering

Description

Hierarchical cluster analysis on a set of dissimilarities and methods for analyzing it.

Usage

hclust(d, method = "complete", members = NULL)

## S3 method for class 'hclust'
plot(x, labels = NULL, hang = 0.1, check = TRUE,
    axes = TRUE, frame.plot = FALSE, ann = TRUE,
    main = "Cluster Dendrogram",
    sub = NULL, xlab = NULL, ylab = "Height", ...)

Arguments

d a dissimilarity structure as produced by dist.

method the agglomeration method to be used. This should be (an unambiguous abbreviation of) one of "ward.D", "ward.D2", "single", "complete", "average" (= UPGMA), "mcquitty" (= WPGMA), "median" (= WPGMC) or "centroid" (= UPGMC).

members NULL or a vector with length size of d. See the ‘Details’ section.

x an object of the type produced by hclust.

hang The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.

check logical indicating if the x object should be checked for validity. This check is not necessary when x is known to be valid such as when it is the direct result of hclust(). The default is check=TRUE, as invalid inputs may crash R due to memory violation in the internal C plotting code.
hclust

labels A character vector of labels for the leaves of the tree. By default the row names or row numbers of the original data are used. If labels = FALSE no labels at all are plotted.

axes, frame.plot, ann logical flags as in plot.default.

main, sub, xlab, ylab character strings for title. sub and xlab have a non-NULL default when there’s a treecall.

... Further graphical arguments. E.g., cex controls the size of the labels (if plotted) in the same way as text.

Details

This function performs a hierarchical cluster analysis using a set of dissimilarities for the n objects being clustered. Initially, each object is assigned to its own cluster and then the algorithm proceeds iteratively, at each stage joining the two most similar clusters, continuing until there is just a single cluster. At each stage distances between clusters are recomputed by the Lance–Williams dissimilarity update formula according to the particular clustering method being used.

A number of different clustering methods are provided. Ward’s minimum variance method aims at finding compact, spherical clusters. The complete linkage method finds similar clusters. The single linkage method (which is closely related to the minimal spanning tree) adopts a ‘friends of friends’ clustering strategy. The other methods can be regarded as aiming for clusters with characteristics somewhere between the single and complete link methods. Note however, that methods "median" and "centroid" are not leading to a monotone distance measure, or equivalently the resulting dendrograms can have so called inversions or reversals which are hard to interpret, but note the trichotomies in Legendre and Legendre (2012).

Two different algorithms are found in the literature for Ward clustering. The one used by option "ward.D" (equivalent to the only Ward option "ward" in R versions ≤ 3.0.3) does not implement Ward’s (1963) clustering criterion, whereas option "ward.D2" implements that criterion (Murtagh and Legendre 2014). With the latter, the dissimilarities are squared before cluster updating. Note that agnes(*, method="ward") corresponds to hclust(*, "ward.D2").

If members != NULL, then d is taken to be a dissimilarity matrix between clusters instead of dissimilarities between singletons and members gives the number of observations per cluster. This way the hierarchical cluster algorithm can be ‘started in the middle of the dendrogram’, e.g., in order to reconstruct the part of the tree above a cut (see examples). Dissimilarities between clusters can be efficiently computed (i.e., without hclust itself) only for a limited number of distance/linkage combinations, the simplest one being squared Euclidean distance and centroid linkage. In this case the dissimilarities between the clusters are the squared Euclidean distances between cluster means.

In hierarchical cluster displays, a decision is needed at each merge to specify which subtree should go on the left and which on the right. Since, for n observations there are n – 1 merges, there are 2^(n–1) possible orderings for the leaves in a cluster tree, or dendrogram. The algorithm used in hclust is to order the subtree so that the tighter cluster is on the left (the last, i.e., most recent, merge of the left subtree is at a lower value than the last merge of the right subtree). Single observations are the tightest clusters possible, and merges involving two observations place them in order by their observation sequence number.

Value

An object of class hclust which describes the tree produced by the clustering process. The object is a list with components:
merge

an \( n - 1 \) by 2 matrix. Row \( i \) of \( \text{merge} \) describes the merging of clusters at step \( i \) of the clustering. If an element \( j \) in the row is negative, then observation \( -j \) was merged at this stage. If \( j \) is positive then the merge was with the cluster formed at the (earlier) stage \( j \) of the algorithm. Thus negative entries in \( \text{merge} \) indicate agglomerations of singletons, and positive entries indicate agglomerations of non-singletons.

height

a set of \( n - 1 \) real values (non-decreasing for ultrametric trees). The clustering height: that is, the value of the criterion associated with the clustering method for the particular agglomeration.

order

a vector giving the permutation of the original observations suitable for plotting, in the sense that a cluster plot using this ordering and matrix \( \text{merge} \) will not have crossings of the branches.

labels

labels for each of the objects being clustered.

call

the call which produced the result.

method

the cluster method that has been used.

dist.method

the distance that has been used to create \( d \) (only returned if the distance object has a "method" attribute).

There are \( \text{print, plot} \) and \( \text{identify} \) (see \( \text{identify.hclust} \)) methods and the \( \text{rect.hclust()} \) function for \( \text{hclust} \) objects.

Note

Method “centroid” is typically meant to be used with squared Euclidean distances.

Author(s)

The \( \text{hclust} \) function is based on Fortran code contributed to STATLIB by F. Murtagh.

Examples

```r
require(graphics)

### Example 1: Violent crime rates by US state

hc <- hclust(dist(USArrests), "ave")
plot(hc)
plot(hc, hang = -1)

## Do the same with centroid clustering and *squared* Euclidean distance,
## cut the tree into ten clusters and reconstruct the upper part of the
## tree from the cluster centers.

hc <- hclust(dist(USArrests)^2, "cen")
memb <- cutree(hc, k = 10)
cent <- NULL
for (k in 1:10){
  cent <- rbind(cent, colMeans(USArrests[memb == k, , drop = FALSE]))
}

c1 <- hclust(dist(cen)^2, method = "cen", members = table(memb))
opar <- par(mfrow = c(1, 2))
plot(hc, labels = FALSE, hang = -1, main = "Original Tree")
plot(hc1, labels = FALSE, hang = -1, main = "Re-start from 10 clusters")
par(opar)
```

Description

A heat map is a false color image (basically `image(t(x))) with a dendrogram added to the left side and to the top. Typically, reordering of the rows and columns according to some set of values (row or column means) within the restrictions imposed by the dendrogram is carried out.

Usage

```r
heatmap(x, Rowv = NULL, Colv = if (symm) "Rowv" else NULL,
        distfun = dist, hclustfun = hclust,
        reorderfun = function(d, w) reorder(d, w),
        add.expr, symm = FALSE, revC = identical(Colv, "Rowv"),
        scale = c("row", "column", "none"), na.rm = TRUE,
        margins = c(5, 5), ColSideColors, RowSideColors,
        cexRow = 0.2 + 1/log10(nr), cexCol = 0.2 + 1/log10(nc),
        labRow = NULL, labCol = NULL, main = NULL,
        xlab = NULL, ylab = NULL,
        keep.dendro = FALSE, verbose =getOption("verbose"), ...)
```
Arguments

- **x**: numeric matrix of the values to be plotted.
- **Rowv**: determines if and how the row dendrogram should be computed and reordered. Either a `dendrogram` or a vector of values used to reorder the row dendrogram or `NA` to suppress any row dendrogram (and reordering) or by default, `NULL`, see ‘Details’ below.
- **Colv**: determines if and how the column dendrogram should be reordered. Has the same options as the Rowv argument above and additionally when `x` is a square matrix, `Colv = "Rowv"` means that columns should be treated identically to the rows (and so if there is to be no row dendrogram there will not be a column one either).
- **distfun**: function used to compute the distance (dissimilarity) between both rows and columns. Defaults to `dist`.
- **hclustfun**: function used to compute the hierarchical clustering when Rowv or Colv are not dendrograms. Defaults to `hclust`. Should take as argument a result of distfun and return an object to which `as.dendrogram` can be applied.
- **reorderfun**: function(d, w) of dendrogram and weights for reordering the row and column dendrograms. The default uses `reorder.dendrogram`.
- **add.expr**: expression that will be evaluated after the call to image. Can be used to add components to the plot.
- **symm**: logical indicating if `x` should be treated symmetrically; can only be true when `x` is a square matrix.
- **revC**: logical indicating if the column order should be reversed for plotting, such that e.g., for the symmetric case, the symmetry axis is as usual.
- **scale**: character indicating if the values should be centered and scaled in either the row direction or the column direction, or none. The default is "row" if symm false, and "none" otherwise.
- **na.rm**: logical indicating whether NA’s should be removed.
- **margins**: numeric vector of length 2 containing the margins (see `par(mar = *)`) for column and row names, respectively.
- **ColSideColors**: (optional) character vector of length ncol(x) containing the color names for a horizontal side bar that may be used to annotate the columns of x.
- **RowSideColors**: (optional) character vector of length nrow(x) containing the color names for a vertical side bar that may be used to annotate the rows of x.
- **cexRow, cexCol**: positive numbers, used as cex.axis in for the row or column axis labeling. The defaults currently only use number of rows or columns, respectively.
- **labRow, labCol**: character vectors with row and column labels to use; these default to rownames(x) or colnames(x), respectively.
- **main, xlab, ylab**: main, x- and y-axis titles; defaults to none.
- **keep.dendro**: logical indicating if the dendrogram(s) should be kept as part of the result (when Rowv and/or Colv are not NA).
- **verbose**: logical indicating if information should be printed.
- **...**: additional arguments passed on to `image`, e.g., col specifying the colors.
heatmap

Details
If either \texttt{Rowv} or \texttt{Colv} are dendrograms they are honored (and not reordered). Otherwise, dendrograms are computed as \( \texttt{dd} \left< \texttt{as.dendrogram(hclustfun(distfun(X)))} \), where \( X \) is either \( x \) or \( t(x) \).

If either is a vector (of `weights`) then the appropriate dendrogram is reordered according to the supplied values subject to the constraints imposed by the dendrogram, by \texttt{reorder(dd, Rowv)}, in the row case. If either is missing, as by default, then the ordering of the corresponding dendrogram is by the mean value of the rows/columns, i.e., in the case of rows, \( \texttt{Rowv} \left< \texttt{rowMeans(x, na.rm = na.rm)} \). If either is \texttt{NA}, no reordering will be done for the corresponding side.

By default (\texttt{scale = "row"}) the rows are scaled to have mean zero and standard deviation one. There is some empirical evidence from genomic plotting that this is useful.

The default colors are not pretty. Consider using enhancements such as the \texttt{RColorBrewer} package.

Value
Invisibly, a list with components

- \texttt{rowInd} : row index permutation vector as returned by \texttt{order.dendrogram}.
- \texttt{colInd} : column index permutation vector.
- \texttt{Rowv} : the row dendrogram; only if input \texttt{Rowv} was not NA and \texttt{keep.dendro} is true.
- \texttt{Colv} : the column dendrogram; only if input \texttt{Colv} was not NA and \texttt{keep.dendro} is true.

Note
Unless \texttt{Rowv} = NA (or \texttt{Colw} = NA), the original rows and columns are reordered \textit{in any case} to match the dendrogram, e.g., the rows by \texttt{order.dendrogram(Rowv)} where \texttt{Rowv} is the (possibly \texttt{reorder}ed) row dendrogram.

\texttt{heatmap()} uses \texttt{layout} and draws the \texttt{image} in the lower right corner of a 2x2 layout. Consequentially, it can \textbf{not} be used in a multi column/row layout, i.e., when \texttt{par(mfrow = \*)} or \texttt{(mfcol = \*)} has been called.

    main = "heatmap(<Mtcars data>, ...., scale = \"column\")")
\end{verbatim}
HoltWinters

## Description

Computes Holt-Winters Filtering of a given time series. Unknown parameters are determined by minimizing the squared prediction error.

## Usage

```r
HoltWinters(x, alpha = NULL, beta = NULL, gamma = NULL,
    seasonal = c("additive", "multiplicative"),
    start.periods = 2, l.start = NULL, b.start = NULL,
    s.start = NULL,
    optim.start = c(alpha = 0.3, beta = 0.1, gamma = 0.1),
    optim.control = list())
```
Arguments

- x: An object of class `ts`.
- beta: `beta` parameter of Holt-Winters Filter. If set to FALSE, the function will do exponential smoothing.
- gamma: `gamma` parameter used for the seasonal component. If set to FALSE, an non-seasonal model is fitted.
- seasonal: Character string to select an "additive" (the default) or "multiplicative" seasonal model. The first few characters are sufficient. (Only takes effect if gamma is non-zero).
- start.periods: Start periods used in the autodetection of start values. Must be at least 2.
- l.start: Start value for level (a[0]).
- b.start: Start value for trend (b[0]).
- s.start: Vector of start values for the seasonal component (s[1][0] ... s[p][0]).
- optim.start: Vector with named components alpha, beta, and gamma containing the starting values for the optimizer. Only the values needed must be specified. Ignored in the one-parameter case.
- optim.control: Optional list with additional control parameters passed to optim if this is used. Ignored in the one-parameter case.

Details

The additive Holt-Winters prediction function (for time series with period length p) is

\[
\hat{Y}[t + h] = a[t] + hb[t] + s[t - p + 1 + (h - 1) \mod p],
\]

where \(a[t]\), \(b[t]\) and \(s[t]\) are given by

\[
a[t] = \alpha(\hat{Y}[t] - s[t - p]) + (1 - \alpha)(a[t - 1] + b[t - 1]) \\
b[t] = \beta(a[t] - a[t - 1]) + (1 - \beta)b[t - 1] \\
s[t] = \gamma(\hat{Y}[t] - a[t]) + (1 - \gamma)s[t - p]
\]

The multiplicative Holt-Winters prediction function (for time series with period length p) is

\[
\hat{Y}[t + h] = (a[t] + hb[t]) \times s[t - p + 1 + (h - 1) \mod p],
\]

where \(a[t]\), \(b[t]\) and \(s[t]\) are given by

\[
a[t] = \alpha(\hat{Y}[t]/s[t - p]) + (1 - \alpha)(a[t - 1] + b[t - 1]) \\
b[t] = \beta(a[t] - a[t - 1]) + (1 - \beta)b[t - 1] \\
s[t] = \gamma(\hat{Y}[t]/a[t]) + (1 - \gamma)s[t - p]
\]

The data in \(x\) are required to be non-zero for a multiplicative model, but it makes most sense if they are all positive.

The function tries to find the optimal values of \(\alpha\) and/or \(\beta\) and/or \(\gamma\) by minimizing the squared one-step prediction error if they are NULL (the default). optimize will be used for the single-parameter case, and optim otherwise.

For seasonal models, start values for \(a\), \(b\) and \(s\) are inferred by performing a simple decomposition in trend and seasonal component using moving averages (see function `decompose`) on the \(\text{start.periods}\) first periods (a simple linear regression on the trend component is used for starting level and trend). For level/trend-models (no seasonal component), start values for \(a\) and \(b\) are \(x[2]\) and \(x[2] - x[1]\), respectively. For level-only models (ordinary exponential smoothing), the start value for \(a\) is \(x[1]\).
Value

An object of class "HoltWinters", a list with components:

- **fitted**: A multiple time series with one column for the filtered series as well as for the level, trend and seasonal components, estimated contemporaneously (that is at time t and not at the end of the series).
- **x**: The original series
- **alpha**: alpha used for filtering
- **beta**: beta used for filtering
- **gamma**: gamma used for filtering
- **coefficients**: A vector with named components a, b, s1, ..., sp containing the estimated values for the level, trend and seasonal components
- **seasonal**: The specified seasonal parameter
- **SSE**: The final sum of squared errors achieved in optimizing
- **call**: The call used

Examples

```r
require(graphics)

## Seasonal Holt-Winters
(m <- HoltWinters(co2))
plot(m)
plot(fitted(m))

(m <- HoltWinters(AirPassengers, seasonal = "mult"))
plot(m)

## Non-Seasonal Holt-Winters
x <- uspop + rnorm(uspop, sd = 5)
m <- HoltWinters(x, gamma = FALSE)
plot(m)

## Exponential Smoothing
m2 <- HoltWinters(x, gamma = FALSE, beta = FALSE)
lines(fitted(m2)[,1], col = 3)
```
The Hypergeometric Distribution

Description

Density, distribution function, quantile function and random generation for the hypergeometric distribution.

Usage

dhyper(x, m, n, k, log = FALSE)
phyper(q, m, n, k, lower.tail = TRUE, log.p = FALSE)
qhyper(p, m, n, k, lower.tail = TRUE, log.p = FALSE)
rhyper(nn, m, n, k)

Arguments

x, q vector of quantiles representing the number of white balls drawn without replacement from an urn which contains both black and white balls.
m the number of white balls in the urn.
n the number of black balls in the urn.
k the number of balls drawn from the urn.
p probability, it must be between 0 and 1.
n number of observations. If length(nn) > 1, the length is taken to be the number required.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The hypergeometric distribution is used for sampling without replacement. The density of this distribution with parameters \( m, n \) and \( k \) (named \( N_p, N - N_p, \) and \( n \), respectively in the reference below) is given by

\[
p(x) = \binom{m}{x} \binom{n}{k-x} / \binom{m+n}{k}
\]

for \( x = 0, \ldots, k \).

The quantile is defined as the smallest value \( x \) such that \( F(x) \geq p \), where \( F \) is the distribution function.

Value

dhyper gives the density, phyper gives the distribution function, qhyper gives the quantile function, and rhyper generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by \( n \) for rhyper, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.
Source

dhyper computes via binomial probabilities, using code contributed by Catherine Loader (see dbinom).

phyper is based on calculating dhyper and phyper(...)/dhyper(...) (as a summation), based on ideas of Ian Smith and Morten Welinder.

qhyper is based on inversion.

References

See Also

*Distributions* for other standard distributions.

Examples

```r
m <- 10; n <- 7; k <- 8
x <- 0:(k+1)
rbind(phyper(x, m, n, k), dhyper(x, m, n, k))
all(phyper(x, m, n, k) == cumsum(dhyper(x, m, n, k))) # FALSE
## but error is very small:
signif(phyper(x, m, n, k) - cumsum(dhyper(x, m, n, k)), digits = 3)
```

**Description**

identify.hclust reads the position of the graphics pointer when the (first) mouse button is pressed. It then cuts the tree at the vertical position of the pointer and highlights the cluster containing the horizontal position of the pointer. Optionally a function is applied to the index of data points contained in the cluster.

**Usage**

```r
## S3 method for class 'hclust'
identify(x, FUN = NULL, N = 20, MAXCLUSTER = 20, DEV.FUN = NULL, ...)
```
**identify.hclust**

**Arguments**

- **x**: an object of the type produced by hclust.
- **FUN**: (optional) function to be applied to the index numbers of the data points in a cluster (see ‘Details’ below).
- **N**: the maximum number of clusters to be identified.
- **MAXCLUSTER**: the maximum number of clusters that can be produced by a cut (limits the effective vertical range of the pointer).
- **DEV.FUN**: (optional) integer scalar. If specified, the corresponding graphics device is made active before FUN is applied.
- **...**: further arguments to FUN.

**Details**

By default clusters can be identified using the mouse and an invisible list of indices of the respective data points is returned.

If FUN is not NULL, then the index vector of data points is passed to this function as first argument, see the examples below. The active graphics device for FUN can be specified using DEV.FUN.

The identification process is terminated by pressing any mouse button other than the first, see also identify.

**Value**

Either a list of data point index vectors or a list of return values of FUN.

**See Also**

hclust, rect.hclust

**Examples**

```R
## Not run:
require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)
(x <- identify(hca)) ## Terminate with 2nd mouse button !!

hci <- hclust(dist(iris[,1:4]))
plot(hci)
identify(hci, function(k) print(table(iris[k,5])))

# open a new device (one for dendrogram, one for bars):
dev.new() # <== make that narrow (& small)
    # and *beside* 1st one
nD <- dev.cur()           # to be for the barplot
dev.set(dev.prev())      # old one for dendrogram
plot(hci)
## select subtrees in dendrogram and "see" the species distribution:
identify(hci, function(k) barplot(table(iris[k,5]), col = 2:4), DEV.FUN = nD)

## End(Not run)
```
**influence.measures**

**Regression Deletion Diagnostics**

**Description**

This suite of functions can be used to compute some of the regression (leave-one-out deletion) diagnostics for linear and generalized linear models discussed in Belsley, Kuh and Welsch (1980), Cook and Weisberg (1982), etc.

**Usage**

```r
influence.measures(model)

rstandard(model, ...)
    ## S3 method for class 'lm'
    rstandard(model, inf1 = lm.influence(model, do.coef = FALSE),
              sd = sqrt(deviance(model)/df.residual(model)), ...)

rstandard(model, inf1 = influence(model, do.coef = FALSE),
          type = c("deviance", "pearson"), ...)

rstudent(model, ...)
    ## S3 method for class 'lm'
    rstudent(model, inf1 = lm.influence(model, do.coef = FALSE),
             res = inf1$wt.res, ...)

rstudent(model, inf1 = influence(model, do.coef = FALSE), ...)

dffits(model, inf1 = , res = )

dfbeta(model, ...)
    ## S3 method for class 'lm'
dfbeta(model, inf1 = lm.influence(model, do.coef = TRUE), ...)

dfbetas(model, ...)
    ## S3 method for class 'lm'
dfbetas(model, inf1 = lm.influence(model, do.coef = TRUE), ...)

covratio(model, inf1 = lm.influence(model, do.coef = FALSE),
          res = weighted.residuals(model))

cooks.distance(model, ...)
    ## S3 method for class 'lm'
cooks.distance(model, inf1 = lm.influence(model, do.coef = FALSE),
               res = weighted.residuals(model),
               sd = sqrt(deviance(model)/df.residual(model)),
               hat = inf1$hat, ...)

cooks.distance(model, inf1 = influence(model, do.coef = FALSE),
               res = inf1$pear.res,
               dispersion = summary(model)$dispersion,
```
hat = infl$hat, ...)

hatvalues(model, ...)
# S3 method for class 'lm'
hatvalues(model, infl = lm.influence(model, do.coef = FALSE), ...)

hat(x, intercept = TRUE)

Arguments

model an R object, typically returned by lm or glm.
inf1 influence structure as returned by lm.influence or influence (the latter only for the glm method of rstudent and cooks.distance).
res (possibly weighted) residuals, with proper default.
sd standard deviation to use, see default.
dispersion dispersion (for glm objects) to use, see default.
hat hat values $H_{ii}$, see default.
type type of residuals for glm method for rstandard.
x the X or design matrix.
intercept should an intercept column be prepended to x?
... further arguments passed to or from other methods.

Details

The primary high-level function is influence.measures which produces a class "infl" object tabular display showing the DFBETAS for each model variable, DFFITS, covariance ratios, Cook’s distances and the diagonal elements of the hat matrix. Cases which are influential with respect to any of these measures are marked with an asterisk.

The functions dfbetas, dffits, covratio and cooks.distance provide direct access to the corresponding diagnostic quantities. Functions rstandard and rstudent give the standardized and Studentized residuals respectively. (These re-normalize the residuals to have unit variance, using an overall and leave-one-out measure of the error variance respectively.)

Values for generalized linear models are approximations, as described in Williams (1987) (except that Cook’s distances are scaled as $F$ rather than as chi-square values). The approximations can be poor when some cases have large influence.

The optional inf1, res and sd arguments are there to encourage the use of these direct access functions, in situations where, e.g., the underlying basic influence measures (from lm.influence or the generic influence) are already available.

Note that cases with weights $\neq 0$ are dropped from all these functions, but that if a linear model has been fitted with na.action = na.exclude, suitable values are filled in for the cases excluded during fitting.

The function hat() exists mainly for S (version 2) compatibility; we recommend using hatvalues() instead.

Note

For hatvalues, dfbeta, and dfbetas, the method for linear models also works for generalized linear models.
Author(s)

Several R core team members and John Fox, originally in his 'car' package.

`influence` (containing `lm.influence`).

`plotmath` for the use of `hat` in plot annotation.

Examples

```r
require(graphics)

## Analysis of the life-cycle savings data
## given in Belsley, Kuh and Welsch.
lm.SR <- lm(sr ~ pop15 + pop75 + dpi + ddpi, data = LifeCycleSavings)

infl.m.SR <- influence.measures(lm.SR)  # which(apply(infl.m.SR$is.inf, 1, any))
# which observations 'are' influential
summary(infl.m.SR)  # only these

infl.m.SR$hat  # all
plot(rstudent(lm.SR) ~ hatvalues(lm.SR))  # recommended by some

## The 'infl' argument is not needed, but avoids recomputation:
rs <- rstandard(lm.SR)
if1SR <- influence(lm.SR)
nidentical(rs, rstandard(lm.SR, infl = if1SR))
## to "see" the larger values:
1000 * round(dfbetas(lm.SR, infl = if1SR), 3)

## Huber's data [Atkinson 1985]
xh <- c(-4:0, 10)
yh <- c(2.48, .73, -.04, -1.44, -1.32, 0)
summary(lmH <- lm(yh ~ xh))

(im <- influence.measures(lmH))
plot(xh,yh, main = "Huber's data: L.S. line and influential obs.")
abline(lmH); points(xh[im$is.inf], yh[im$is.inf], pch = 20, col = 2)

## Irwin's data [Williams 1987]
xi <- 1:5
yi <- c(0,2,14,19,30)  # number of mice responding to dose xi
```
### Description

Adaptive quadrature of functions of one variable over a finite or infinite interval.

### Usage

```r
integrate(f, lower, upper, ..., subdivisions = 100L, 
  rel.tol = .Machine$double.eps^0.25, abs.tol = rel.tol, 
  stop.on.error = TRUE, keep.xy = FALSE, aux = NULL)
```

### Arguments

- **f**: an R function taking a numeric first argument and returning a numeric vector of the same length. Returning a non-finite element will generate an error.
- **lower**, **upper**: the limits of integration. Can be infinite.
- **...**: additional arguments to be passed to `f`.
- **subdivisions**: the maximum number of subintervals.
- **rel.tol**: relative accuracy requested.
- **abs.tol**: absolute accuracy requested.
- **stop.on.error**: logical. If true (the default) an error stops the function. If false some errors will give a result with a warning in the `message` component.
- **keep.xy**: unused. For compatibility with S.
- **aux**: unused. For compatibility with S.

### Details

Note that arguments after `...` must be matched exactly.

If one or both limits are infinite, the infinite range is mapped onto a finite interval.

For a finite interval, globally adaptive interval subdivision is used in connection with extrapolation by Wynn’s Epsilon algorithm, with the basic step being Gauss–Kronrod quadrature. `rel.tol` cannot be less than `max(50*.Machine$double.eps, 0.5e-28)` if `abs.tol <= 0`.

### Value

A list of class "integrate" with components

- **value**: the final estimate of the integral.
- **abs.error**: estimate of the modulus of the absolute error.
- **subdivisions**: the number of subintervals produced in the subdivision process.
- **message**: "OK" or a character string giving the error message.
- **call**: the matched call.
Note

Like all numerical integration routines, these evaluate the function on a finite set of points. If the function is approximately constant (in particular, zero) over nearly all its range it is possible that the result and error estimate may be seriously wrong.

When integrating over infinite intervals do so explicitly, rather than just using a large number as the endpoint. This increases the chance of a correct answer – any function whose integral over an infinite interval is finite must be near zero for most of that interval.

For values at a finite set of points to be a fair reflection of the behaviour of the function elsewhere, the function needs to be well-behaved, for example differentiable except perhaps for a small number of jumps or integrable singularities.

\( f \) must accept a vector of inputs and produce a vector of function evaluations at those points. The \texttt{Vectorize} function may be helpful to convert \( f \) to this form.

Source

Based on QUADPACK routines \texttt{dqags} and \texttt{dqagi} by R. Piessens and E. deDoncker–Kapenga, available from Netlib.

integrate(dnorm, -Inf, Inf)
```

```r
# a slowly-convergent integral
integrand <- function(x) {1/((x+1)*sqrt(x))}
integrate(integrand, lower = 0, upper = Inf)
```

```r
# don’t do this if you really want the integral from 0 to Inf
integrate(integrand, lower = 0, upper = 10)
integrate(integrand, lower = 0, upper = 100000)
integrate(integrand, lower = 0, upper = 1000000, stop.on.error = FALSE)
```

```r
# some functions do not handle vector input properly
f <- function(x) 2.0
try(integrate(f, 0, 1))
integrate(Vectorize(f), 0, 1)  # correct
integrate(function(x) rep(2.0, length(x)), 0, 1)  # correct
```

```r
# integrate can fail if misused
integrate(dnorm, 0, 2)
integrate(dnorm, 0, 20)
integrate(dnorm, 0, 200)
integrate(dnorm, 0, 2000)
integrate(dnorm, 0, 20000)  # fails on many systems
integrate(dnorm, 0, Inf)  # works
```
interaction.plot

Two-way Interaction Plot

Description

Plots the mean (or other summary) of the response for two-way combinations of factors, thereby illustrating possible interactions.

Usage

interaction.plot(x.factor, trace.factor, response, fun = mean,
  type = c("l", "p", "b", "o", "c"), legend = TRUE,
  trace.label = deparse(substitute(trace.factor)),
  fixed = FALSE,
  xlab = deparse(substitute(x.factor)),
  ylab = ylabel,
  ylim = range(cells, na.rm = TRUE),
  lty = nc:1, col = 1, pch = c(1:9, 0, letters),
  xpd = NULL, leg.bg = par("bg"), leg.bty = "n",
  xtick = FALSE, xaxt = par("xaxt"), axes = TRUE,
  ...)

Arguments

x.factor a factor whose levels will form the x axis.
trace.factor another factor whose levels will form the traces.
response a numeric variable giving the response
fun the function to compute the summary. Should return a single real value.
type the type of plot (see plot.default): lines or points or both.
legend logical. Should a legend be included?
trace.label overall label for the legend.
fixed logical. Should the legend be in the order of the levels of trace.factor or in the order of the traces at their right-hand ends?
xlab,ylab the x and y label of the plot each with a sensible default.
ylim numeric of length 2 giving the y limits for the plot.
lty line type for the lines drawn, with sensible default.
col the color to be used for plotting.
pch a vector of plotting symbols or characters, with sensible default.
xpd determines clipping behaviour for the legend used, see par(xpd). Per default, the legend is not clipped at the figure border.
leg.bg, leg.bty arguments passed to legend().
xtick logical. Should tick marks be used on the x axis?
xaxt, axes, ... graphics parameters to be passed to the plotting routines.
interaction.plot

Details

By default the levels of \( x.\text{factor} \) are plotted on the x axis in their given order, with extra space left at the right for the legend (if specified). If \( x.\text{factor} \) is an ordered factor and the levels are numeric, these numeric values are used for the x axis.

The response and hence its summary can contain missing values. If so, the missing values and the line segments joining them are omitted from the plot (and this can be somewhat disconcerting).

The graphics parameters xlab, ylab, ylim, col and pch are given suitable defaults (and xlim and xaxs are set and cannot be overridden). The defaults are to cycle through the line types, use the foreground colour, and to use the symbols 1:9, 0, and the capital letters to plot the traces.

Note

Some of the argument names and the precise behaviour are chosen for S-compatibility.

Examples

```r
require(graphics)
with(ToothGrowth, {
  interaction.plot(dose, supp, len, fixed = TRUE)
  dose <- ordered(dose)
  interaction.plot(dose, supp, len, fixed = TRUE, col = 2:3, leg.bty = "o")
  interaction.plot(dose, supp, len, fixed = TRUE, col = 2:3, type = "p")
})

with(OrchardSprays, {
  interaction.plot(treatment, rowpos, decrease)
  interaction.plot(rowpos, treatment, decrease, cex.axis = 0.8)
  ## order the rows by their mean effect
  rowpos <- factor(rowpos,
                  levels = sort.list(tapply(decrease, rowpos, mean)))
  interaction.plot(rowpos, treatment, decrease, col = 2:9, lty = 1)
})

with(esoph, {
  interaction.plot(agegp, alcgp, ncases/ncontrols, main = "'esoph' Data")
  interaction.plot(agegp, tobgp, ncases/ncontrols, trace.label = "tobacco",
                  fixed = TRUE, xaxt = "n")
})
## deal with NAs:
esoph[66,] # second to last age group: 65-74
esophNA <- esoph; esophNA$ncases[66] <- NA
with(esophNA, {
  interaction.plot(agegp, alcgp, ncases/ncontrols, col = 2:5)
  # doesn't show *last* group either
  interaction.plot(agegp, alcgp, ncases/ncontrols, col = 2:5, type = "b")
  ## alternative take non-NA's ("cheating")
  interaction.plot(agegp, alcgp, ncases/ncontrols, col = 2:5,
                 fun = function(x) mean(x, na.rm = TRUE),
                 # doesn't show *last* group either
  interaction.plot(agegp, alcgp, ncases/ncontrols, col = 2:5, type = "b")
  # doesn't show *last* group either
  interaction.plot(agegp, alcgp, ncases/ncontrols, col = 2:5,
                 fun = function(x) mean(x, na.rm = TRUE),
  })
```
The Interquartile Range

Description

computes interquartile range of the $x$ values.

Usage

$IQR(x, \text{na.rm} = \text{FALSE}, \text{type} = 7)$

Arguments

- **x**: a numeric vector.
- **na.rm**: logical. Should missing values be removed?
- **type**: an integer selecting one of the many quantile algorithms, see `quantile`.

Details

Note that this function computes the quartiles using the `quantile` function rather than following Tukey’s recommendations, i.e., $IQR(x) = \text{quantile}(x, 3/4) - \text{quantile}(x, 1/4)$.

For normally $N(m, 1)$ distributed $X$, the expected value of $IQR(X)$ is $2\times qnorm(3/4) = 1.3490$, i.e., for a normal-consistent estimate of the standard deviation, use $IQR(x) / 1.349$.

References

`fivenum`, `mad` which is more robust, `range`, `quantile`.

Examples

$IQR(\text{rivers})$
is.empty.model

Test if a Model's Formula is Empty

Description

R's formula notation allows models with no intercept and no predictors. These require special handling internally. `is.empty.model()` checks whether an object describes an empty model.

Usage

`is.empty.model(x)`

Arguments

`x`  
A `terms` object or an object with a `terms` method.

Value

`TRUE` if the model is empty

See Also

`lm, glm`

Examples

```r
y <- rnorm(20)
is.empty.model(y ~ 0)
is.empty.model(y ~ -1)
is.empty.model(lm(y ~ 0))
```

isoreg

Isotonic / Monotone Regression

Description

Compute the isotonic (monotonely increasing nonparametric) least squares regression which is piecewise constant.

Usage

`isoreg(x, y = NULL)`

Arguments

`x, y`  
coordinate vectors of the regression points. Alternatively a single plotting structure can be specified: see `xy.coords`. 
isoreg

Details

The algorithm determines the convex minorant \( m(x) \) of the cumulative data (i.e., \( \text{cumsum}(y) \)) which is piecewise linear and the result is \( m'(x) \), a step function with level changes at locations where the convex \( m(x) \) touches the cumulative data polygon and changes slope. \( \text{as.stepfun()} \) returns a \texttt{stepfun} object which can be more parsimonious.

Value

\texttt{isoreg()} returns an object of class \texttt{isoreg} which is basically a list with components

\begin{itemize}
  \item \texttt{x} \quad \text{original (constructed) abscissa values } x.
  \item \texttt{y} \quad \text{corresponding } y \text{ values.}
  \item \texttt{yf} \quad \text{fitted values corresponding to } \text{ordered} \ x \text{ values.}
  \item \texttt{yc} \quad \text{cumulative } y \text{ values corresponding to } \text{ordered} \ x \text{ values.}
  \item \texttt{iKnots} \quad \text{integer vector giving indices where the fitted curve jumps, i.e., where the convex minorant has kinks.}
  \item \texttt{isOrd} \quad \text{logical indicating if original } x \text{ values were ordered increasingly already.}
  \item \texttt{ord} \quad \text{if(!!isOrd): integer permutation } \text{order}(x) \text{ of original } x.
  \item \texttt{call} \quad \text{the } \texttt{call} \text{ to isoreg()} \text{ used.}
\end{itemize}

Note

The code should be improved to accept \texttt{weights} additionally and solve the corresponding weighted least squares problem.

‘Patches are welcome!’

the plotting method \texttt{plot.isoreg} with more examples; \texttt{isoMDS()} from the \texttt{MASS} package internally uses isotonic regression.

Examples

\texttt{require(graphics)}

\begin{verbatim}
(ir <- isoreg(c(1,0,4,3,3,5,4,2,0)))
plot(ir, plot.type = "row")

(ir3 <- isoreg(y3 <- c(1,0,4,3,3,5,4,2, 3))) # last "3", not "0"
(f13 <- as.stepfun(ir3))
(ir4 <- isoreg(1:10, y4 <- c(5, 9, 1:2, 5:8, 3, 8)))
cat(sprintf("R^2 = %6.2f\n",
    1 - sum(residuals(ir4)^2) / ((10-1)*var(y4)))

## If you are interested in the knots alone :
\end{verbatim}
KalmanLike

with(ir4, cbind(iKnots, yf[iKnots]))

## Example of unordered x[] with ties:
x <- sample((0:30)/8)
y <- exp(x)
x. <- round(x) # ties!
plot(m <- isoreg(x, y))
stopifnot(all.equal(with(m, yf[iKnots]),
                   as.vector(tapply(y, x., mean))))

KalmanLike  Kalman Filtering

Description

Use Kalman Filtering to find the (Gaussian) log-likelihood, or for forecasting or smoothing.

Usage

KalmanLike(y, mod, nit = 0L, update = FALSE)
KalmanRun(y, mod, nit = 0L, update = FALSE)
KalmanSmooth(y, mod, nit = 0L)
KalmanForecast(n.ahead = 10L, mod, update = FALSE)

makeARIMA(phi, theta, Delta, kappa = 1e6,
          SSinit = c("Gardner1980", "Rossignol2011"),
          tol = .Machine$double.eps)

Arguments

y  a univariate time series.
mod  a list describing the state-space model: see ‘Details’.
nit  the time at which the initialization is computed. nit = 0L implies that the initialization is for a one-step prediction, so Pn should not be computed at the first step.
update  if TRUE the update mod object will be returned as attribute ”mod” of the result.
n.ahead  the number of steps ahead for which prediction is required.
phi, theta  numeric vectors of length ≥ 0 giving AR and MA parameters.
Delta  vector of differencing coefficients, so an ARMA model is fitted to y[t] - Delta[1]*y[t-1] - ....
kappa  the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model.
SSinit  a string specifying the algorithm to compute the Pn part of the state-space initialization; see ‘Details’.
tol  tolerance eventually passed to solve.default when SSinit = "Rossignol2011".
KalmanLike

Details

These functions work with a general univariate state-space model with state vector ‘a’, transitions ‘a <- T a + R e’, e ~ N(0,κQ) and observation equation ‘y = Z’a + eta’, (eta ≡ η), η ~ N(0,κh). The likelihood is a profile likelihood after estimation of κ.

The model is specified as a list with at least components

- T the transition matrix
- Z the observation coefficients
- h the observation variance
- V ‘RQR’
- a the current state estimate
- P the current estimate of the state uncertainty matrix Q
- Pn the estimate at time t – 1 of the state uncertainty matrix Q (not updated by KalmanForecast).

KalmanSmooth is the workhorse function for tsSmooth.

makeARIMA constructs the state-space model for an ARIMA model, see also arima.

The state-space initialization has used Gardner et al’s method (SSinit = “Gardner1980”), as only method for years. However, that suffers sometimes from deficiencies when close to non-stationarity. For this reason, it may be replaced as default in the future and only kept for reproducibility reasons. Explicit specification of SSinit is therefore recommended, notably also in arima(). The “Rossignol2011” method has been proposed and partly documented by Raphael Rossignol, Univ. Grenoble, on 2011-09-20 (see PR#14682, below), and later been ported to C by Matwey V. Kornilov. It computes the covariance matrix of (X_{t-1}, ..., X_{t-p}, Z_{t}, ..., Z_{t-q}) by the method of difference equations (page 93 of Brockwell and Davis), apparently suggested by a referee of Gardner et al (see p.314 of their paper).

Value

For KalmanLike, a list with components Lik (the log-likelihood less some constants) and s2, the estimate of κ.

For KalmanRun, a list with components values, a vector of length 2 giving the output of KalmanLike, resid (the residuals) and states, the contemporaneous state estimates, a matrix with one row for each observation time.

For KalmanSmooth, a list with two components. Component smooth is a n by p matrix of state estimates based on all the observations, with one row for each time. Component var is a n by p by p array of variance matrices.

For KalmanForecast, a list with components pred, the predictions, and var, the unscaled variances of the prediction errors (to be multiplied by s2).

For makeARIMA, a model list including components for its arguments.

Warning

These functions are designed to be called from other functions which check the validity of the arguments passed, so very little checking is done.

Examples

```r
## an ARIMA fit
fit3 <- arima(presidents, c(3, 0, 0))
predict(fit3, 12)
## reconstruct this
pr <- KalmanForecast(12, fit3$model)
pr$pred + fit3$coef[4]
sqrt(pr$var * fit3$sigma2)
## and now do it year by year
mod <- fit3$model
for(y in 1:3) {
  pr <- KalmanForecast(4, mod, TRUE)
  print(list(pred = pr$pred + fit3$coef["intercept"],
             se = sqrt(pr$var * fit3$sigma2)))
  mod <- attr(pr, "mod")
}
```

---

cornapply (Apply Smoothing Kernel)

Description

kernapply computes the convolution between an input sequence and a specific kernel.

Usage

```r
kernapply(x, ...)
```

## Default S3 method:
kernapply(x, k, circular = FALSE, ...)

## S3 method for class 'ts'
kernapply(x, k, circular = FALSE, ...)

## S3 method for class 'vector'
kernapply(x, k, circular = FALSE, ...)

## S3 method for class 'tskernel'
kernapply(x, k, ...)
Arguments

- **x**: an input vector, matrix, time series or kernel to be smoothed.
- **k**: smoothing "tskernel" object.
- **circular**: a logical indicating whether the input sequence to be smoothed is treated as circular, i.e., periodic.
- **...**: arguments passed to or from other methods.

Value

A smoothed version of the input sequence.

Note

This uses **fft** to perform the convolution, so is fastest when NROW(x) is a power of 2 or some other highly composite integer.

Author(s)

A. Trapletti

See Also

- kernel, convolve, filter, spectrum

Examples

```r
## see 'kernel' for examples
```
Arguments

coef    the upper half of the smoothing kernel coefficients (including coefficient zero) or the name of a kernel (currently "daniell", "dirichlet", "fejer" or "modified.daniell").

m       the kernel dimension(s) if coef is a name. When m has length larger than one, it means the convolution of kernels of dimension  \( m[j] \) for \( j \) in 1:length(m). Currently this is supported only for the named "*daniell" kernels.

name    the name the kernel will be called.

r       the kernel order for a Fejer kernel.

type, xlab, ylab, main, ... arguments passed to plot.default.

Details

kernel is used to construct a general kernel or named specific kernels. The modified Daniell kernel halves the end coefficients (as used by S-PLUS).

The \( \{ \) method allows natural indexing of kernel objects with indices in \((-m):m\). The normalization is such that for \( k <- kernel(*) \), \( \text{sum}(k[\ -k\circ m : k\circ m]) \) is one.

df.kernel returns the ‘equivalent degrees of freedom’ of a smoothing kernel as defined in Brockwell and Davis (1991), page 362, and bandwidth.kernel returns the equivalent bandwidth as defined in Bloomfield (1976), p. 201, with a continuity correction.

Value

kernel() returns an object of class "tskernel" which is basically a list with the two components coef and the kernel dimension m. An additional attribute is "name".

Author(s)

A. Trapletti; modifications by B.D. Ripley

kernapply

Examples

```r
require(graphics)

## Demonstrate a simple trading strategy for the financial time series German stock index DAX.
x <- EuStockMarkets[,1]
k1 <- kernel("daniell", 50) # a long moving average
k2 <- kernel("daniell", 10) # and a short one
```
kmeans

Description

Perform k-means clustering on a data matrix.

Usage

kmeans(x, centers, iter.max = 10, nstart = 1,
        algorithm = c("Hartigan-Wong", "Lloyd", "Forgy",
                      "MacQueen"), trace=FALSE)

## S3 method for class 'kmeans'
 fitted(object, method = c("centers", "classes"), ...)

Arguments

x numeric matrix of data, or an object that can be coerced to such a matrix (such
as a numeric vector or a data frame with all numeric columns).

centers either the number of clusters, say k, or a set of initial (distinct) cluster centres.
If a number, a random set of (distinct) rows in x is chosen as the initial centres.

iter.max the maximum number of iterations allowed.

nstart if centers is a number, how many random sets should be chosen?

algorithm character: may be abbreviated. Note that "Lloyd" and "Forgy" are alternative
names for one algorithm.

object an R object of class "kmeans", typically the result ob of ob <- kmeans(...).

method character: may be abbreviated. "centers" causes fitted to return cluster cen-
ters (one for each input point) and "classes" causes fitted to return a vector of
class assignments.

trace logical or integer number, currently only used in the default method
("Hartigan-Wong"): if positive (or true), tracing information on the progress
of the algorithm is produced. Higher values may produce more tracing information.

... not used.
**Details**

The data given by \( x \) are clustered by the \( k \)-means method, which aims to partition the points into \( k \) groups such that the sum of squares from points to the assigned cluster centres is minimized. At the minimum, all cluster centres are at the mean of their Voronoi sets (the set of data points which are nearest to the cluster centre).

The algorithm of Hartigan and Wong (1979) is used by default. Note that some authors use \( k \)-means to refer to a specific algorithm rather than the general method: most commonly the algorithm given by MacQueen (1967) but sometimes that given by Lloyd (1957) and Forgy (1965). The Hartigan–Wong algorithm generally does a better job than either of those, but trying several random starts (\( n_{\text{start}} > 1 \)) is often recommended. In rare cases, when some of the points (rows of \( x \)) are extremely close, the algorithm may not converge in the “Quick-Transfer” stage, signalling a warning (and returning \( i_{\text{fault}} = 4 \)). Slight rounding of the data may be advisable in that case.

For ease of programmatic exploration, \( k = 1 \) is allowed, notably returning the center and \( \text{withinss} \).

Except for the Lloyd–Forgy method, \( k \) clusters will always be returned if a number is specified. If an initial matrix of centres is supplied, it is possible that no point will be closest to one or more centres, which is currently an error for the Hartigan–Wong method.

**Value**

`kmeans` returns an object of class "kmeans" which has a `print` and a `fitted` method. It is a list with at least the following components:

- `cluster` A vector of integers (from 1:k) indicating the cluster to which each point is allocated.
- `centers` A matrix of cluster centres.
- `totss` The total sum of squares.
- `withinss` Vector of within-cluster sum of squares, one component per cluster.
- `tot.withinss` Total within-cluster sum of squares, i.e. \( \sum(\text{withinss}) \).
- `betweenss` The between-cluster sum of squares, i.e. \( \text{totss} - \text{tot.withinss} \).
- `size` The number of points in each cluster.
- `iter` The number of (outer) iterations.

kruskal.test

Kruskal-Wallis Rank Sum Test

Description

Performs a Kruskal-Wallis rank sum test.

Usage

kruskal.test(x, ...)

## Default S3 method:
kruskal.test(x, g, ...) 

## S3 method for class 'formula'
kruskal.test(formula, data, subset, na.action, ...)

kruskal.test

Arguments

x     a numeric vector of data values, or a list of numeric data vectors. Non-numeric elements of a list will be coerced, with a warning.
g     a vector or factor object giving the group for the corresponding elements of x. Ignored with a warning if x is a list.
formula a formula of the form response ~ group where response gives the data values and group a vector or factor of the corresponding groups.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").
... further arguments to be passed to or from methods.

Details

kruskal.test performs a Kruskal-Wallis rank sum test of the null that the location parameters of the distribution of x are the same in each group (sample). The alternative is that they differ in at least one.

If x is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, g is ignored, and one can simply use kruskal.test(x) to perform the test. If the samples are not yet contained in a list, use kruskal.test(list(x, ...)).

Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

Value

A list with class "htest" containing the following components:

statistic  the Kruskal-Wallis rank sum statistic.
parameter  the degrees of freedom of the approximate chi-squared distribution of the test statistic.
p.value   the p-value of the test.
method     the character string "Kruskal-Wallis rank sum test".
data.name  a character string giving the names of the data.

References

See Also

wilcox.test in package coin for exact, asymptotic and Monte Carlo conditional p-values, including in the presence of ties.
Examples

```r
## Hollander & Wolfe (1973), 116.
## Mucociliary efficiency from the rate of removal of dust in normal
## subjects, subjects with obstructive airway disease, and subjects
## with asbestosis.
x <- c(2.9, 3.0, 2.5, 2.6, 3.2)  # normal subjects
y <- c(3.8, 2.7, 4.8, 2.4)       # with obstructive airway disease
z <- c(2.8, 3.4, 3.7, 2.2, 2.0) # with asbestosis
ks.test(list(x, y, z))
## Equivalently,
x <- c(x, y, z)
g <- factor(rep(1:3, c(5, 4, 5)),
           labels = c("Normal subjects",
                      "Subjects with obstructive airway disease",
                      "Subjects with asbestosis"))
ks.test(x, g)

## Formula interface.
require(graphics)
boxplot(Ozone ~ Month, data = airquality)
ks.test(Ozone ~ Month, data = airquality)
```

ks.test

**Kolmogorov-Smirnov Tests**

### Description

Perform a one- or two-sample Kolmogorov-Smirnov test.

#### Usage

```r
ks.test(x, y, ..., alternative = c("two.sided", "less", "greater"),
        exact = NULL)
```

#### Arguments

- **x**: a numeric vector of data values.
- **y**: either a numeric vector of data values, or a character string naming a cumulative distribution function or an actual cumulative distribution function such as `pnorm`. Only continuous CDFs are valid.
- **...**: parameters of the distribution specified (as a character string) by y.
- **alternative**: indicates the alternative hypothesis and must be one of "two.sided" (default), "less", or "greater". You can specify just the initial letter of the value, but the argument name must be give in full. See 'Details' for the meanings of the possible values.
- **exact**: NULL or a logical indicating whether an exact p-value should be computed. See 'Details' for the meaning of NULL. Not available in the two-sample case for a one-sided test or if ties are present.
Details

If y is numeric, a two-sample test of the null hypothesis that x and y were drawn from the same continuous distribution is performed.

Alternatively, y can be a character string naming a continuous (cumulative) distribution function, or such a function. In this case, a one-sample test is carried out of the null that the distribution function which generated x is distribution y with parameters specified by . . .

The presence of ties always generates a warning, since continuous distributions do not generate them. If the ties arose from rounding the tests may be approximately valid, but even modest amounts of rounding can have a significant effect on the calculated statistic.

Missing values are silently omitted from x and (in the two-sample case) y.

The possible values "two.sided", "less" and "greater" of alternative specify the null hypothesis that the true distribution function of x is equal to, not less than or not greater than the hypothesized distribution function (one-sample case) or the distribution function of y (two-sample case), respectively. This is a comparison of cumulative distribution functions, and the test statistic is the maximum difference in value, with the statistic in the "greater" alternative being $D^+ = \max_u [F_x(u) - F_y(u)]$. Thus in the two-sample case alternative = "greater" includes distributions for which x is stochastically smaller than y (the CDF of x lies above and hence to the left of that for y), in contrast to t.test or wilcox.test.

Exact p-values are not available for the two-sample case if one-sided or in the presence of ties. If exact = NULL (the default), an exact p-value is computed if the sample size is less than 100 in the one-sample case and there are no ties, and if the product of the sample sizes is less than 10000 in the two-sample case. Otherwise, asymptotic distributions are used whose approximations may be inaccurate in small samples. In the one-sample two-sided case, exact p-values are obtained as described in Marsaglia, Tsang & Wang (2003) (but not using the optional approximation in the right tail, so this can be slow for small p-values). The formula of Birnbaum & Tingey (1951) is used for the one-sample one-sided case.

If a single-sample test is used, the parameters specified in . . . must be pre-specified and not estimated from the data. There is some more refined distribution theory for the KS test with estimated parameters (see Durbin, 1973), but that is not implemented in ks.test.

Value

A list with class "htest" containing the following components:

- statistic: the value of the test statistic.
- p.value: the p-value of the test.
- alternative: a character string describing the alternative hypothesis.
- method: a character string indicating what type of test was performed.
- data.name: a character string giving the name(s) of the data.

Source

References

**ksmooth**

The Nadaraya–Watson kernel regression estimate.

**Usage**

\[
\text{ksmooth}(x, y, \text{kernel} = \text{c("box", "normal")}, \text{bandwidth} = 0.5, \\
\text{range.x} = \text{range}(x), \\
\text{n.points} = \text{max}(100L, \text{length}(x)), \text{x.points})
\]

**Arguments**

- **x**: input x values. Long vectors are supported.
- **y**: input y values. Long vectors are supported.
- **kernel**: the kernel to be used.
- **bandwidth**: the bandwidth. The kernels are scaled so that their quartiles (viewed as probability densities) are at \( \pm 0.25 \times \text{bandwidth} \).
- **range.x**: the range of points to be covered in the output.
- **n.points**: the number of points at which to evaluate the fit.
- **x.points**: points at which to evaluate the smoothed fit. If missing, \( \text{n.points} \) are chosen uniformly to cover \text{range.x}. Long vectors are supported.
Value

A list with components
- **x**: values at which the smoothed fit is evaluated. Guaranteed to be in increasing order.
- **y**: fitted values corresponding to `x`.

Note

This function was implemented for compatibility with S, although it is nowhere near as slow as the S function. Better kernel smoothers are available in other packages such as **KernSmooth**.

Examples

```r
require(graphics)
with(cars, {
  plot(speed, dist)
  lines(ksmooth(speed, dist, "normal", bandwidth = 2), col = 2)
  lines(ksmooth(speed, dist, "normal", bandwidth = 5), col = 3)
})
```

---

### lag

**Lag a Time Series**

Description

Compute a lagged version of a time series, shifting the time base back by a given number of observations.

**lag** is a generic function; this page documents its default method.

Usage

```r
lag(x, ...)
```

## Default S3 method:

```r
lag(x, k = 1, ...)
```

Arguments

- **x**: A vector or matrix or univariate or multivariate time series
- **k**: The number of lags (in units of observations).
- **...**: further arguments to be passed to or from methods.

Details

Vector or matrix arguments `x` are given a `tsp` attribute via `hasTsp`.

Value

A time series object with the same class as `x`. 
**Note**

Note the sign of k: a series lagged by a positive k starts earlier.

**References**

**See Also**

diff, deltat

**Examples**

```
lag(deaths, 12) # starts one year earlier
```

---

**Description**

Plot time series against lagged versions of themselves. Helps visualizing ‘auto-dependence’ even when auto-correlations vanish.

**Usage**

```
lag.plot(x, lags = 1, layout = NULL, set.lags = 1:lags, 
main = NULL, asp = 1, 
diag = TRUE, diag.col = "gray", type = "p", oma = NULL, 
ask = NULL, do.lines = (n <= 150), labels = do.lines, 
...)
```

**Arguments**

- **x**: time-series (univariate or multivariate)
- **lags**: number of lag plots desired, see arg `set.lags`.
- **layout**: the layout of multiple plots, basically the `mfrow` `par()` argument. The default uses about a square layout (see `n2mfrow` such that all plots are on one page.
- **set.lags**: vector of positive integers allowing specification of the set of lags used; defaults to 1:lags.
- **main**: character with a main header title to be done on the top of each page.
- **asp**: Aspect ratio to be fixed, see `plot.default`.
- **diag**: logical indicating if the x=y diagonal should be drawn.
- **diag.col**: color to be used for the diagonal if(diag).
- **type**: plot type to be used, but see `plot.ts` about its restricted meaning.
- **oma**: outer margins, see `par`.
- **ask**: logical or NULL; if true, the user is asked to confirm before a new page is started.
- **do.lines**: logical indicating if lines should be drawn.
labels

Further arguments to \texttt{plot.ts}. Several graphical parameters are set in this function and so cannot be changed: these include \texttt{xlab}, \texttt{ylab}, \texttt{mgp}, \texttt{col.lab} and \texttt{font.lab}: this also applies to the arguments \texttt{xy.labels} and \texttt{xy.lines}.

**Details**

If just one plot is produced, this is a conventional plot. If more than one plot is to be produced, \texttt{par(mfrow)} and several other graphics parameters will be set, so it is not (easily) possible to mix such lag plots with other plots on the same page.

If \texttt{ask = NULL}, \texttt{par(ask = TRUE)} will be called if more than one page of plots is to be produced and the device is interactive.

**Note**

It is more flexible and has different default behaviour than the \texttt{S} version. We use \texttt{main} = instead of \texttt{head = } for internal consistency.

**Author(s)**

Martin Maechler

**See Also**

\texttt{plot.ts} which is the basic work horse.

**Examples**

```r
require(graphics)

lag.plot(nhtemp, 8, diag.col = "forest green")
lag.plot(nhtemp, 5, main = "Average Temperatures in New Haven")
## ask defaults to TRUE when we have more than one page:
lag.plot(nhtemp, 6, layout = c(2,1), asp = NA,
       main = "New Haven Temperatures", col.main = "blue")

## Multivariate (but non-stationary! ...)
lag.plot(freeny.x, lags = 3)

## no lines for long series :
lag.plot(sqrt(sunspots), set = c(1:4, 9:12), pch = ".", col = "gold")
```

**Description**

Fit a line robustly as recommended in *Exploratory Data Analysis*.

**Usage**

\texttt{line(x, y)}
Arguments

\( x, y \)  
the arguments can be any way of specifying \( x-y \) pairs. See \textit{xy coords}.

Details

Cases with missing values are omitted.
Long vectors are not supported.

Value

An object of class "tukeyline".
Methods are available for the generic functions \texttt{coef}, \texttt{residuals}, \texttt{fitted}, and \texttt{print}.

References

See Also

\texttt{lm}.

Examples

```r
require(graphics)
plot(cars)
(z <- line(cars))
abline(coef(z))
## Tukey-Anscombe Plot:
plot(residuals(z) ~ fitted(z), main = deparse(z$call))
```

---

\textbf{listof}  
\textit{A Class for Lists of (Parts of) Model Fits}

Description

Class "\texttt{listof}" is used by \texttt{aov} and the "\texttt{lm}" method of \texttt{alias} for lists of model fits or parts thereof. It is simply a list with an assigned class to control the way methods, especially printing, act on it.

It has a \texttt{coef} method in this package (which returns an object of this class), and \texttt{[} and \texttt{print} methods in package \texttt{base}. 
**lm**  
*Fitting Linear Models*

**Description**

`lm` is used to fit linear models. It can be used to carry out regression, single stratum analysis of variance and analysis of covariance (although `aov` may provide a more convenient interface for these).

**Usage**

```r
lm(formula, data, subset, weights, na.action,  
    method = "qr", model = TRUE, x = FALSE, y = FALSE, qr = TRUE,  
    singular.ok = TRUE, contrasts = NULL, offset, ...)  
```

**Arguments**

- **formula**: an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under ‘Details’.
- **data**: an optional data frame, list or environment (or object coercible by `as.data.frame`) containing the variables in the model. If not found in `data`, the variables are taken from `environment(formula)`, typically the environment from which `lm` is called.
- **subset**: an optional vector specifying a subset of observations to be used in the fitting process.
- **weights**: an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector. If non-NULL, weighted least squares is used with weights `weights` (that is, minimizing \( \sum(w*e^2) \)); otherwise ordinary least squares is used. See also ‘Details’;
- **na.action**: a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The ‘factory-fresh’ default is `na.omit`. Another possible value is `null`, no action. Value `na.exclude` can be useful.
- **method**: the method to be used; for fitting, currently only `method = "qr"` is supported; `method = "model.frame"` returns the model frame (the same as with `model = TRUE`, see below).
- **model, x, y, qr**: logicals. If TRUE the corresponding components of the fit (the model frame, the model matrix, the response, the QR decomposition) are returned.
- **singular.ok**: logical. If FALSE (the default in S but not in R) a singular fit is an error.
- **contrasts**: an optional list. See the `contrasts.arg` of `model.matrix.default`.
- **offset**: this can be used to specify an *a priori* known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases. One or more `offset` terms can be included in the formula instead or as well, and if more than one are specified their sum is used. See `model.offset`.
- **...**: additional arguments to be passed to the low level regression fitting functions (see below).
Details

Models for *lm* are specified symbolically. A typical model has the form \( \text{response} \sim \text{terms} \) where \text{response} is the (numeric) response vector and \text{terms} is a series of terms which specifies a linear predictor for \text{response}. A terms specification of the form \text{first + second} indicates all the terms in \text{first} together with all the terms in \text{second} with duplicates removed. A specification of the form \text{first:second} indicates the set of terms obtained by taking the interactions of all terms in \text{first} with all terms in \text{second}. The specification \text{first*second} indicates the \text{cross} of \text{first} and \text{second}. This is the same as \text{first + second + first:second}.

If the formula includes an \text{offset}, this is evaluated and subtracted from the response.

If \text{response} is a matrix a linear model is fitted separately by least-squares to each column of the matrix.

See \code{model.matrix} for some further details. The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a \text{terms} object as the formula (see \code{aov} and \code{demo(glm.vr)} for an example).

A formula has an implied intercept term. To remove this use either \text{y ~ x - 1} or \text{y ~ 0 + x}. See \code{formula} for more details of allowed formulae.

Non-NULL weights can be used to indicate that different observations have different variances (with the values in \text{weights} being inversely proportional to the variances); or equivalently, when the elements of \text{weights} are positive integers \(w_i\), that each response \(y_i\) is the mean of \(w_i\) unit-weight observations (including the case that there are \(w_i\) observations equal to \(y_i\) and the data have been summarized).

\text{lm} calls the lower level functions \text{lm.fit}, etc, see below, for the actual numerical computations. For programming only, you may consider doing likewise.

All of \text{weights}, \text{subset} and \text{offset} are evaluated in the same way as variables in \code{formula}, that is first in \text{data} and then in the environment of \code{formula}.

Value

\text{lm} returns an object of \code{class} "\text{lm}" or for multiple responses of class \code{c("mlm", "lm")}.

The functions \code{summary} and \code{anova} are used to obtain and print a summary and analysis of variance table of the results. The generic accessor functions \code{coefficients}, \code{effects}, \code{fitted.values} and \code{residuals} extract various useful features of the value returned by \text{lm}.

An object of class "\text{lm}" is a list containing at least the following components:

- \code{coefficients}: a named vector of coefficients
- \code{residuals}: the residuals, that is response minus fitted values.
- \code{fitted.values}: the fitted mean values.
- \code{rank}: the numeric rank of the fitted linear model.
- \code{weights}: (only for weighted fits) the specified weights.
- \code{df.residual}: the residual degrees of freedom.
- \code{call}: the matched call.
- \code{terms}: the \text{terms} object used.
- \code{contrasts}: (only where relevant) the contrasts used.
- \code{xlevels}: (only where relevant) a record of the levels of the factors used in fitting.
- \code{offset}: the offset used (missing if none were used).
- \code{y}: if requested, the response used.
In addition, non-null fits will have components `assign`, `effects` and (unless not requested) `qr` relating to the linear fit, for use by extractor functions such as `summary` and `effects`.

### Using time series

Considerable care is needed when using `lm` with time series.

Unless `na.action = NULL`, the time series attributes are stripped from the variables before the regression is done. (This is necessary as omitting `NAs` would invalidate the time series attributes, and if `NAs` are omitted in the middle of the series the result would no longer be a regular time series.)

Even if the time series attributes are retained, they are not used to line up series, so that the time shift of a lagged or differenced regressor would be ignored. It is good practice to prepare a data argument by `ts.intersect(...)`, `dframe = TRUE`, then apply a suitable `na.action` to that data frame and call `lm` with `na.action = NULL` so that residuals and fitted values are time series.

### Note

Offsets specified by `offset` will not be included in predictions by `predict.lm`, whereas those specified by an offset term in the formula will be.

### Author(s)

The design was inspired by the S function of the same name described in Chambers (1992). The implementation of model formula by Ross Ihaka was based on Wilkinson & Rogers (1973).

plot(lm.D9, las = 1)  # Residuals, Fitted, ...
par(par)

### less simple examples in "See Also" above
```

Description

These are the basic computing engines called by `lm` used to fit linear models. These should usually not be used directly unless by experienced users. `.lm.fit()` is bare bone wrapper to the innermost QR-based C code, on which `glm.fit` and `lsfit` are based as well, for even more experienced users.

Usage

```r
lm.fit(x, y, offset = NULL, method = "qr", tol = 1e-7,
       singular.ok = TRUE, ...)

lm.wfit(x, y, w, offset = NULL, method = "qr", tol = 1e-7,
       singular.ok = TRUE, ...)

.lm.fit(x, y, tol = 1e-7)
```

Arguments

- `x` design matrix of dimension n * p.
- `y` vector of observations of length n, or a matrix with n rows.
- `w` vector of weights (length n) to be used in the fitting process for the wfit functions. Weighted least squares is used with weights w, i.e., sum(w * e^2) is minimized.
- `offset` numeric of length n). This can be used to specify an a priori known component to be included in the linear predictor during fitting.
- `method` currently, only method = "qr" is supported.
- `tol` tolerance for the qr decomposition. Default is 1e-7.
singul.ok: logical. If FALSE, a singular model is an error.

Value

a list with components (for \texttt{lm.fit} and \texttt{lm.wfit})

- coefficients: \textbf{p} vector
- residuals: \textbf{n} vector or matrix
- fitted.values: \textbf{n} vector or matrix
- effects: \textbf{n} vector of orthogonal single-df effects. The first rank of them correspond to non-aliased coefficients, and are named accordingly.
- weights: \textbf{n} vector — \textit{only} for the \texttt{*wfit*} functions.
- rank: integer, giving the rank
- df.residual: degrees of freedom of residuals
- qr: the QR decomposition, see \texttt{qr}.

Fits without any columns or non-zero weights do not have the \texttt{effects} and \texttt{qr} components.

\texttt{lm.fit()} returns a subset of the above, the \texttt{qr} part unwrapped, plus a logical component \texttt{pivoted} indicating if the underlying QR algorithm did pivot.

See Also

\texttt{lm} which you should use for linear least squares regression, unless you know better.

Examples

```r
require(utils)
set.seed(129)
n <- 7; p <- 2
X <- matrix(rnorm(n * p), n, p) # no intercept!
y <- rnorm(n)
w <- rnorm(n)^2
str(lmw <- lm.wfit(x = X, y = y, w = w))
str(lm. <- lm.fit (x = X, y = y))

if(require("microbenchmark")) {
  mb <- microbenchmark(lm(y~X), lm.fit(X,y), .lm.fit(X,y))
  print(mb)
  boxplot(mb, notch=TRUE)
}
```

Description

This function provides the basic quantities which are used in forming a wide variety of diagnostics for checking the quality of regression fits.

Usage

```r
influence(model, ...)  
## S3 method for class 'lm'
influence(model, do.coef = TRUE, ...)  
## S3 method for class 'glm'
influence(model, do.coef = TRUE, ...)  
```

Arguments

- **model**: an object as returned by `lm` or `glm`.
- **do.coef**: logical indicating if the changed coefficients (see below) are desired. These need $O(n^2p)$ computing time.
- ... further arguments passed to or from other methods.

Details

The `influence.measures()` and other functions listed in See Also provide a more user oriented way of computing a variety of regression diagnostics. These all build on `lm.influence`. Note that for GLMs (other than the Gaussian family with identity link) these are based on one-step approximations which may be inadequate if a case has high influence.

An attempt is made to ensure that computed hat values that are probably one are treated as one, and the corresponding rows in `sigma` and `coefficients` are NaN. (Dropping such a case would normally result in a variable being dropped, so it is not possible to give simple drop-one diagnostics.)

`naresid` is applied to the results and so will fill in with NAs if the fit had `na.action = na.exclude`.

Value

A list containing the following components of the same length or number of rows $n$, which is the number of non-zero weights. Cases omitted in the fit are omitted unless a `na.action` method was used (such as `na.exclude`) which restores them.

- **hat**: a vector containing the diagonal of the ‘hat’ matrix.
- **coefficients**: (unless `do.coef` is false) a matrix whose i-th row contains the change in the estimated coefficients which results when the i-th case is dropped from the regression. Note that aliased coefficients are not included in the matrix.
- **sigma**: a vector whose i-th element contains the estimate of the residual standard deviation obtained when the i-th case is dropped from the regression. (The approximations needed for GLMs can result in this being NaN.)
- **wt.res**: a vector of weighted (or for class `glm` rather `deviance`) residuals.
Note

The coefficients returned by the R version of `lm.influence` differ from those computed by S. Rather than returning the coefficients which result from dropping each case, we return the changes in the coefficients. This is more directly useful in many diagnostic measures. Since these need $O(n^2p)$ computing time, they can be omitted by `do.coef = FALSE`.

Note that cases with weights equals 0 are dropped (contrary to the situation in S).

If a model has been fitted with `na.action = na.exclude` (see `na.exclude`), cases excluded in the fit are considered here.

References

See the list in the documentation for `influence.measures`.

`lm.summaries`  

Accessing Linear Model Fits

Description

All these functions are methods for class "lm" objects.

Usage

```r
## S3 method for class 'lm'
family(object, ...)

## S3 method for class 'lm'
formula(x, ...)

## S3 method for class 'lm'
residuals(object,  
    type = c("working", "response", "deviance", "pearson", 
```
Arguments

object, x an object inheriting from class lm, usually the result of a call to lm or aov.
... further arguments passed to or from other methods.
type the type of residuals which should be returned.

Details

The generic accessor functions coef, effects, fitted and residuals can be used to extract various useful features of the value returned by lm.

The working and response residuals are ‘observed - fitted’. The deviance and pearson residuals are weighted residuals, scaled by the square root of the weights used in fitting. The partial residuals are a matrix with each column formed by omitting a term from the model. In all these, zero weight cases are never omitted (as opposed to the standardized rstudent residuals, and the weighted.residuals).

How residuals treats cases with missing values in the original fit is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear, with residual value NA. See also naresid.

The "lm" method for generic labels returns the term labels for estimable terms, that is the names of the terms with at least one estimable coefficient.

influence.measures for deletion diagnostics, including standardized (rstandard) and studentized (rstudent) residuals.

Examples

###-- Continuing the lm(.) example:
coef(lm(D90)) # the bare coefficients

## The 2 basic regression diagnostic plots [plot.lm(.) is preferred]
plot(resid(lm.D90), fitted(lm.D90)) # Tukey-Anscombe's
abline(h = 0, lty = 2, col = "gray")

qqnorm(residuals(lm.D90))
Print Loadings in Factor Analysis

Description

Extract or print loadings in factor analysis (or principal components analysis).

Usage

```r
loadings(x, ...)  # S3 method for class 'loadings'
print(x, digits = 3, cutoff = 0.1, sort = FALSE, ...)
```

Arguments

- `x`: an object of class "factanal" or "princomp" or the loadings component of such an object.
- `digits`: number of decimal places to use in printing uniquenesses and loadings.
- `cutoff`: loadings smaller than this (in absolute value) are suppressed.
- `sort`: logical. If true, the variables are sorted by their importance on each factor. Each variable with any loading larger than 0.5 (in modulus) is assigned to the factor with the largest loading, and the variables are printed in the order of the factor they are assigned to, then those unassigned.
- `...`: further arguments for other methods, ignored for loadings.

Details

'Loadings' is a term from factor analysis, but because factor analysis and principal component analysis (PCA) are often conflated in the social science literature, it was used for PCA by SPSS and hence by princomp in S-PLUS to help SPSS users.

Small loadings are conventionally not printed (replaced by spaces), to draw the eye to the pattern of the larger loadings.

The print method for class "factanal" calls the "loadings" method to print the loadings, and so passes down arguments such as cutoff and sort.

The signs of the loadings vectors are arbitrary for both factor analysis and PCA.

Note

There are other functions called loadings in contributed packages which are S3 or S4 generic: the ... argument is to make it easier for this one to become a default method.

factanal, princomp
**Description**

Fit a polynomial surface determined by one or more numerical predictors, using local fitting.

**Usage**

```r
loess(formula, data, weights, subset, na.action, model = FALSE,
       span = 0.75, enp.target, degree = 2,
       parametric = FALSE, drop.square = FALSE, normalize = TRUE,
       family = c("gaussian", "symmetric"),
       method = c("loess", "model.frame"),
       control = loess.control(...), ...
)```

**Arguments**

- `formula` a formula specifying the numeric response and one to four numeric predictors (best specified via an interaction, but can also be specified additively). Will be coerced to a formula if necessary.
- `data` an optional data frame, list or environment (or object coercible by `as.data.frame`) containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which `loess` is called.
- `weights` optional weights for each case.
- `subset` an optional specification of a subset of the data to be used.
- `na.action` the action to be taken with missing values in the response or predictors. The default is given by `getOption("na.action")`.
- `model` should the model frame be returned?
- `span` the parameter $\alpha$ which controls the degree of smoothing.
- `enp.target` an alternative way to specify `span`, as the approximate equivalent number of parameters to be used.
- `degree` the degree of the polynomials to be used, normally 1 or 2. (Degree 0 is also allowed, but see the 'Note'.)
- `parametric` should any terms be fitted globally rather than locally? Terms can be specified by name, number or as a logical vector of the same length as the number of predictors.
- `drop.square` for fits with more than one predictor and degree = 2, should the quadratic term be dropped for particular predictors? Terms are specified in the same way as for `parametric`.
- `normalize` should the predictors be normalized to a common scale if there is more than one? The normalization used is to set the 10% trimmed standard deviation to one. Set to false for spatial coordinate predictors and others know to be a common scale.
- `family` if "gaussian" fitting is by least-squares, and if "symmetric" a re-descending M estimator is used with Tukey’s biweight function.
- `method` fit the model or just extract the model frame.
- `control` control parameters: see `loess.control`.
- `...` control parameters can also be supplied directly.
Details

Fitting is done locally. That is, for the fit at point \( x \), the fit is made using points in a neighbourhood of \( x \), weighted by their distance from \( x \) (with differences in ‘parametric’ variables being ignored when computing the distance). The size of the neighbourhood is controlled by \( \alpha \) (set by span or \texttt{enp.target}). For \( \alpha < 1 \), the neighbourhood includes proportion \( \alpha \) of the points, and these have tricubic weighting (proportional to \( (1 - (\text{dist}/\max\text{dist})^3)^3 \)). For \( \alpha > 1 \), all points are used, with the ‘maximum distance’ assumed to be \( \alpha^{1/p} \) times the actual maximum distance for \( p \) explanatory variables.

For the default family, fitting is by (weighted) least squares. For \texttt{family="symmetric"} a few iterations of an M-estimation procedure with Tukey’s biweight are used. Be aware that as the initial value is the least-squares fit, this need not be a very resistant fit.

It can be important to tune the control list to achieve acceptable speed. See \texttt{loess.control} for details.

Value

An object of class \texttt{"loess"}.

Note

As this is based on \texttt{cloess}, it is similar to but not identical to the \texttt{loess} function of S. In particular, conditioning is not implemented.

The memory usage of this implementation of \texttt{loess} is roughly quadratic in the number of points, with 1000 points taking about 10Mb.

\texttt{degree = 0}, local constant fitting, is allowed in this implementation but not documented in the reference. It seems very little tested, so use with caution.

Author(s)

B. D. Ripley, based on the \texttt{cloess} package of Cleveland, Grosse and Shyu.

Source

The 1998 version of \texttt{cloess} package of Cleveland, Grosse and Shyu. A later version is available as \texttt{cloess} at \url{http://www.netlib.org/a}.

References

\texttt{loess.control}, \texttt{predict.loess}.

\texttt{lowess}, the ancestor of \texttt{loess} (with different defaults!).

Examples

```r
  cars.lo <- loess(dist ~ speed, cars)
predict(cars.lo, data.frame(speed = seq(5, 30, 1)), se = TRUE)
# to allow extrapolation
cars.lo2 <- loess(dist ~ speed, cars,
```
control = loess.control(surface = "direct")
predict(cars.lo2, data.frame(speed = seq(5, 30, 1)), se = TRUE)

---

**loess.control**  
*Set Parameters for Loess*

**Description**

Set control parameters for `loess` fits.

**Usage**

```r
loess.control(surface = c("interpolate", "direct"),
              statistics = c("approximate", "exact"),
              trace.hat = c("exact", "approximate"),
              cell = 0.2, iterations = 4, ...)
```

**Arguments**

- `surface` should the fitted surface be computed exactly or via interpolation from a kd tree?
- `statistics` should the statistics be computed exactly or approximately? Exact computation can be very slow.
- `trace.hat` should the trace of the smoother matrix be computed exactly or approximately? It is recommended to use the approximation for more than about 1000 data points.
- `cell` if interpolation is used this controls the accuracy of the approximation via the maximum number of points in a cell in the kd tree. Cells with more than `floor(n*span*cell)` points are subdivided.
- `iterations` the number of iterations used in robust fitting.
- `...` further arguments which are ignored.

**Value**

A list with components

- `surface`
- `statistics`
- `trace.hat`
- `cell`
- `iterations`

with meanings as explained under ‘Arguments’.

**See Also**

`loess`
The Logistic Distribution

Description

Density, distribution function, quantile function and random generation for the logistic distribution with parameters location and scale.

Usage

dlogis(x, location = 0, scale = 1, log = FALSE)
plogis(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qlogis(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rlogis(n, location = 0, scale = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
location, scale location and scale parameters.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

If location or scale are omitted, they assume the default values of 0 and 1 respectively.

The Logistic distribution with location = \( \mu \) and scale = \( \sigma \) has distribution function

\[
F(x) = \frac{1}{1 + e^{-(x-\mu)/\sigma}}
\]

and density

\[
f(x) = \frac{1}{\sigma} \frac{e^{(x-\mu)/\sigma}}{(1 + e^{(x-\mu)/\sigma})^2}
\]

It is a long-tailed distribution with mean \( \mu \) and variance \( \pi^2/3\sigma^2 \).

Value

dlogis gives the density, plogis gives the distribution function, qlogis gives the quantile function, and rlogis generates random deviates.

The length of the result is determined by n for rlogis, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.
logLik

Note

qlogis(p) is the same as the well known 'logit' function, \( \text{logit}(p) = \log p/(1−p) \), and plogis(x) has consequently been called the 'inverse logit'.

The distribution function is a rescaled hyperbolic tangent, \( \text{plogis}(x) = (1+ \tanh(x/2))/2 \), and it is called a sigmoid function in contexts such as neural networks.

Source

[dpq]logis are calculated directly from the definitions.

rlogis uses inversion.

References

See Also

Distributions for other standard distributions.

Examples

\[
\text{var(rlogis(4000, 0, scale = 5))} \quad \# \text{approximately } (+/- 3) \\
\pi^2/3 + 5^2
\]

logLik

Extract Log-Likelihood

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which have methods for this function include: "glm", "lm", "nls" and "Arima". Packages contain methods for other classes, such as "fitdistr", "negbin" and "polr" in package MASS, "multinom" in package nnet and "gls", "gnls" "lme" and others in package nlme.

Usage

logLik(object, ...)

## S3 method for class 'lm'
logLik(object, REML = FALSE, ...)

Arguments

object any object from which a log-likelihood value, or a contribution to a log-likelihood value, can be extracted.

... some methods for this generic function require additional arguments.

REML an optional logical value. If TRUE the restricted log-likelihood is returned, else, if FALSE, the log-likelihood is returned. Defaults to FALSE.
Details

logLik is most commonly used for a model fitted by maximum likelihood, and some uses, e.g. by AIC, assume this. So care is needed where other fit criteria have been used, for example REML (the default for "lme").

For a "glm" fit the family does not have to specify how to calculate the log-likelihood, so this is based on using the family’s aic() function to compute the AIC. For the gaussian, Gamma and inverse.gaussian families it assumed that the dispersion of the GLM is estimated and has been counted as a parameter in the AIC value, and for all other families it is assumed that the dispersion is known. Note that this procedure does not give the maximized likelihood for "glm" fits from the Gamma and inverse gaussian families, as the estimate of dispersion used is not the MLE.

For "lm" fits it is assumed that the scale has been estimated (by maximum likelihood or REML), and all the constants in the log-likelihood are included. That method is only applicable to single-response fits.

Value

Returns an object of class logLik. This is a number with at least one attribute, "df" (degrees of freedom), giving the number of (estimated) parameters in the model.

There is a simple print method for "logLik" objects.

There may be other attributes depending on the method used: see the appropriate documentation. One that is used by several methods is "nobs", the number of observations used in estimation (after the restrictions if REML = TRUE).

Author(s)

José Pinheiro and Douglas Bates

AIC

Examples

x <- 1:5
lmx <- lm(x ~ 1)
logLik(lmx) # using print.logLik() method
utils::str(logLik(lmx))

## lm method
(fm1 <- lm(rating ~ ., data = attitude))
logLik(fm1)
logLik(fm1, REML = TRUE)

utils::data(Orthodont, package = "nlme")
fm1 <- lm(distance ~ Sex * age, Orthodont)
Description

loglin is used to fit log-linear models to multidimensional contingency tables by Iterative Proportional Fitting.

Usage

loglin(table, margin, start = rep(1, length(table)), fit = FALSE, 
eps = 0.1, iter = 20, param = FALSE, print = TRUE)

Arguments

table  a contingency table to be fit, typically the output from table.

margin a list of vectors with the marginal totals to be fit.

(Hierarchical) log-linear models can be specified in terms of these marginal totals which give the ‘maximal’ factor subsets contained in the model. For example, in a three-factor model, list(c(1, 2), c(1, 3)) specifies a model which contains parameters for the grand mean, each factor, and the 1-2 and 1-3 interactions, respectively (but no 2-3 or 1-2-3 interaction), i.e., a model where factors 2 and 3 are independent conditional on factor 1 (sometimes represented as ‘[12][13]’).

The names of factors (i.e., names(dimnames(table))) may be used rather than numeric indices.

start a starting estimate for the fitted table. This optional argument is important for incomplete tables with structural zeros in table which should be preserved in the fit. In this case, the corresponding entries in start should be zero and the others can be taken as one.

fit a logical indicating whether the fitted values should be returned.

eps maximum deviation allowed between observed and fitted margins.

iter maximum number of iterations.

param a logical indicating whether the parameter values should be returned.

print a logical. If TRUE, the number of iterations and the final deviation are printed.

Details

The Iterative Proportional Fitting algorithm as presented in Haberman (1972) is used for fitting the model. At most iter iterations are performed, convergence is taken to occur when the maximum deviation between observed and fitted margins is less than eps. All internal computations are done in double precision; there is no limit on the number of factors (the dimension of the table) in the model.

Assuming that there are no structural zeros, both the Likelihood Ratio Test and Pearson test statistics have an asymptotic chi-squared distribution with df degrees of freedom.
Note that the IPF steps are applied to the factors in the order given in margin. Hence if the model is decomposable and the order given in margin is a running intersection property ordering then IPF will converge in one iteration.

Package MASS contains loglm, a front-end to loglin which allows the log-linear model to be specified and fitted in a formula-based manner similar to that of other fitting functions such as lm or glm.

Value

A list with the following components.

- `lrt` the Likelihood Ratio Test statistic.
- `pearson` the Pearson test statistic (X-squared).
- `df` the degrees of freedom for the fitted model. There is no adjustment for structural zeros.
- `margin` list of the margins that were fit. Basically the same as the input margin, but with numbers replaced by names where possible.
- `fit` An array like table containing the fitted values. Only returned if fit is TRUE.
- `param` A list containing the estimated parameters of the model. The ‘standard’ constraints of zero marginal sums (e.g., zero row and column sums for a two factor parameter) are employed. Only returned if param is TRUE.

```r
## Model with no three-factor interactions fits well.
```
The Log Normal Distribution

Description
Density, distribution function, quantile function and random generation for the log normal distribution whose logarithm has mean equal to meanlog and standard deviation equal to sdlog.

Usage
- dlnorm(x, meanlog = 0, sdlog = 1, log = FALSE)
- plnorm(q, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
- qlnorm(p, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
- rlnorm(n, meanlog = 0, sdlog = 1)

Arguments
- x, q: vector of quantiles.
- p: vector of probabilities.
- n: number of observations. If length(n) > 1, the length is taken to be the number required.
- meanlog, sdlog: mean and standard deviation of the distribution on the log scale with default values of 0 and 1 respectively.
- log, log.p: logical; if TRUE, probabilities p are given as log(p).
- lower.tail: logical; if TRUE (default), probabilities are P[X ≤ x], otherwise, P[X > x].

Details
The log normal distribution has density

\[ f(x) = \frac{1}{\sqrt{2\pi\sigma x}} e^{-\frac{(\log(x) - \mu)^2}{2\sigma^2}} \]

where \( \mu \) and \( \sigma \) are the mean and standard deviation of the logarithm. The mean is \( E(X) = \exp(\mu + 1/2\sigma^2) \), the median is \( \text{med}(X) = \exp(\mu) \), and the variance \( \text{Var}(X) = \exp(2\mu + \sigma^2)(\exp(\sigma^2) - 1) \) and hence the coefficient of variation is \( \sqrt{\exp(\sigma^2) - 1} \) which is approximately \( \sigma \) when that is small (e.g., \( \sigma < 1/2 \)).

Value
dlnorm gives the density, plnorm gives the distribution function, qlnorm gives the quantile function, and rlnorm generates random deviates.

The length of the result is determined by n for rlnorm, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note
The cumulative hazard \( H(t) = -\log(1-F(t)) \) is -plnorm(t, r, lower = FALSE, log = TRUE).
Source

d`dnrm` is calculated from the definition (in ‘Details’). `[pqr]nrm` are based on the relationship to the normal.

Consequently, they model a single point mass at `exp(meanLog)` for the boundary case `sdlog = 0`.

See Also

Distributions for other standard distributions, including `dnorm` for the normal distribution.

Examples

d`dnorm(1) == dnorm(0)`

---

**lowess**  
*Scatter Plot Smoothing*

Description

This function performs the computations for the LOWESS smoother which uses locally-weighted polynomial regression (see the references).

Usage

`lowess(x, y = NULL, f = 2/3, iter = 3, delta = 0.01 * diff(range(x)))`

Arguments

- `x, y` vectors giving the coordinates of the points in the scatter plot. Alternatively a single plotting structure can be specified – see `xy.coords`.
- `f` the smoother span. This gives the proportion of points in the plot which influence the smooth at each value. Larger values give more smoothness.
- `iter` the number of ‘robustifying’ iterations which should be performed. Using smaller values of `iter` will make lowess run faster.
- `delta` See ‘Details’. Defaults to 1/100th of the range of `x`. 
**Details**

`lowess` is defined by a complex algorithm, the Ratfor original of which (by W. S. Cleveland) can be found in the R sources as file `src/app/lowess.doc`. Normally a local linear polynomial fit is used, but under some circumstances (see the file) a local constant fit can be used. ‘Local’ is defined by the distance to the $\text{floor}(f \times n)$th nearest neighbour, and tricubic weighting is used for $x$ which fall within the neighbourhood.

The initial fit is done using weighted least squares. If $\text{iter} > 0$, further weighted fits are done using the product of the weights from the proximity of the $x$ values and case weights derived from the residuals at the previous iteration. Specifically, the case weight is Tukey’s biweight, with cutoff 6 times the MAD of the residuals. (The current R implementation differs from the original in stopping iteration if the MAD is effectively zero since the algorithm is highly unstable in that case.)

delta is used to speed up computation: instead of computing the local polynomial fit at each data point it is not computed for points within delta of the last computed point, and linear interpolation is used to fill in the fitted values for the skipped points.

**Value**

`lowess` returns a list containing components $x$ and $y$ which give the coordinates of the smooth. The smooth can be added to a plot of the original points with the function `lines`: see the examples.

**References**

**See Also**

`loess`, a newer formula based version of `lowess` (with different defaults!).

**Examples**

```r
require(graphics)
plot(cars, main = "lowess(cars)"
lines(lowess(cars), col = 2)
lines(lowess(cars, f = .2), col = 3)
legend(5, 120, c(paste("f = ", c("2/3", ".2"))), lty = 1, col = 2:3)
```
Usage

ls.diag(ls.out)

Arguments

ls.out Typically the result of `lsfit()`

Value

A list with the following numeric components.

- `std.dev`: The standard deviation of the errors, an estimate of $\sigma$.
- `hat`: diagonal entries $h_{ii}$ of the hat matrix $H$
- `std.res`: standardized residuals
- `stud.res`: studentized residuals
- `cooks`: Cook’s distances
- `dfits`: DFITS statistics
- `correlation`: correlation matrix
- `std.err`: standard errors of the regression coefficients
- `cov.scaled`: Scaled covariance matrix of the coefficients
- `cov.unscaled`: Unscaled covariance matrix of the coefficients

References

See Also

`hat` for the hat matrix diagonals, `ls.print`, `lm.influence`, `summary.lm`, `anova`.

Examples

```r
###-- Using the same data as the lm(.) example:
lsD9 <- lsfit(x = as.numeric(gl(2, 10, 20)), y = weight)
dlsD9 <- ls.diag(lsD9)
utils::str(dlsD9, give.attr = FALSE)
abs(1 - sum(dlsD9$hat) / 2) < 10*.Machine$double.eps # sum(h.ii) = p
plot(dlsD9$hat, dlsD9$stud.res, xlim = c(0, 0.11))
abline(h = 0, lty = 2, col = "lightgray")
```
ls.print  

Print lsfit Regression Results

Description

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients and prints them if print.it is TRUE.

Usage

ls.print(ls.out, digits = 4, print.it = TRUE)

Arguments

- `ls.out`: Typically the result of `lsfit()`
- `digits`: The number of significant digits used for printing
- `print.it`: a logical indicating whether the result should also be printed

Value

A list with the components

- `summary`: The ANOVA table of the regression
- `coef.table`: matrix with regression coefficients, standard errors, t- and p-values

Note

Usually you would use `summary(lm(...))` and `anova(lm(...))` to obtain similar output.

See Also

`ls.diag`, `lsfit`, also for examples; `lm`, `lm.influence` which usually are preferable.

lsfit  

Find the Least Squares Fit

Description

The least squares estimate of $\beta$ in the model

$$ Y = X \beta + \epsilon $$

is found.

Usage

lsfit(x, y, wt = NULL, intercept = TRUE, tolerance = 1e-07, yname = NULL)
Arguments

x  a matrix whose rows correspond to cases and whose columns correspond to variables.
y  the responses, possibly a matrix if you want to fit multiple left hand sides.
wt an optional vector of weights for performing weighted least squares.
intercept whether or not an intercept term should be used.
tolerance the tolerance to be used in the matrix decomposition.
ynames to be used for the response variables.

Details

If weights are specified then a weighted least squares is performed with the weight given to the jth case specified by the jth entry in wt.

If any observation has a missing value in any field, that observation is removed before the analysis is carried out. This can be quite inefficient if there is a lot of missing data.

The implementation is via a modification of the LINPACK subroutines which allow for multiple left-hand sides.

Value

A list with the following named components:

coef  the least squares estimates of the coefficients in the model (\( \beta \) as stated above).
residuals  residuals from the fit.
intercept  indicates whether an intercept was fitted.
qr  the QR decomposition of the design matrix.

References

See Also

*lm* which usually is preferable: *ls.print*, *ls.diag*.

Examples

```
## As the same data as the lm(.) example:
lsD9 <- lsfit(x = unclass(glm(2, 10)), y = weight)
ls.print(lsD9)
```
Median Absolute Deviation

Description
Compute the median absolute deviation, i.e., the (lo-/hi-) median of the absolute deviations from the median, and (by default) adjust by a factor for asymptotically normal consistency.

Usage
mad(x, center = median(x), constant = 1.4826, na.rm = FALSE, 
low = FALSE, high = FALSE)

Arguments
x a numeric vector.
center Optionally, the centre: defaults to the median.
constant scale factor.
na.rm if TRUE then NA values are stripped from x before computation takes place.
low if TRUE, compute the ‘lo-median’, i.e., for even sample size, do not average the two middle values, but take the smaller one.
high if TRUE, compute the ‘hi-median’, i.e., take the larger of the two middle values for even sample size.

Details
The actual value calculated is constant * cMedian(abs(x - center)) with the default value of center being median(x), and cMedian being the usual, the ‘low’ or ‘high’ median, see the arguments description for low and high above.
The default constant = 1.4826 (approximately $1/\Phi^{-1}(\frac{3}{2}) = 1/qnorm(3/4)$) ensures consistency, i.e.,
\[ E[\text{mad}(X_1, \ldots, X_n)] = \sigma \]
for $X_i$ distributed as $N(\mu, \sigma^2)$ and large $n$.
If na.rm is TRUE then NA values are stripped from x before computation takes place. If this is not done then an NA value in x will cause mad to return NA.

See Also
IQR which is simpler but less robust, median, var.

Examples
mad(c(1:9))
print(mad(c(1:9), constant = 1)) ==
mad(c(1:8, 100), constant = 1) # = 2 ; TRUE
x <- c(1,2,3,5,7,8)
sort(abs(x - median(x)))
c(mad(x, constant = 1),
  mad(x, constant = 1, low = TRUE),
  mad(x, constant = 1, high = TRUE))
mahalanobis  

**Mahalanobis Distance**

**Description**

Returns the squared Mahalanobis distance of all rows in \( x \) and the vector \( \mu = \text{center} \) with respect to \( \Sigma = \text{cov} \). This is (for vector \( x \)) defined as

\[
D^2 = (x - \mu)'\Sigma^{-1}(x - \mu)
\]

**Usage**

```
mahalanobis(x, center, cov, inverted = FALSE, ...)
```

**Arguments**

- **x**: vector or matrix of data with, say, \( p \) columns.
- **center**: mean vector of the distribution or second data vector of length \( p \).
- **cov**: covariance matrix \((p \times p)\) of the distribution.
- **inverted**: logical. If TRUE, \( \text{cov} \) is supposed to contain the inverse of the covariance matrix.
- **...**: passed to `solve` for computing the inverse of the covariance matrix (if `inverted` is false).

**See Also**

cov, var

**Examples**

```
require(graphics)

ma <- cbind(1:6, 1:3)
(S <- var(ma))
mahalanobis(c(0, 0), 1:2, S)

x <- matrix(rnorm(100*3), ncol = 3)
stopifnot(mahalanobis(x, 0, diag(ncol(x))) == rowSums(x**x))
  # Here, D^2 = usual squared Euclidean distances

Sx <- cov(x)
D2 <- mahalanobis(x, colMeans(x), Sx)
plot(density(D2, bw = 0.5),
     main="Squared Mahalanobis distances, n=100, p=3") ; rug(D2)
quplot(qchisq(ppoints(100), df = 3), D2,
       main = expression("Q-Q plot of Mahalanobis* ~ D^2 *
                           " vs. quantiles of* ~ chi[3]^2"))
abline(0, 1, col = 'gray')
```
**make.link**

Create a Link for GLM Families

**Description**

This function is used with the `family` functions in `glm()`. Given the name of a link, it returns a link function, an inverse link function, the derivative \( \frac{d\mu}{d\eta} \) and a function for domain checking.

**Usage**

```r
make.link(link)
```

**Arguments**

- `link` character; one of "logit", "probit", "cauchit", "cloglog", "identity", "log", "sqrt", "1/mu^2", "inverse".

**Value**

A object of class "link-glm", a list with components

- `linkfun` Link function function(\( \mu \))
- `linkinv` Inverse link function function(\( \eta \))
- `mu.eta` Derivative function(\( \eta \)) \( \frac{d\mu}{d\eta} \)
- `valideta` function(\( \eta \)) \{ TRUE if \( \eta \) is in the domain of `linkinv` \}
- `name` a name to be used for the link

**See Also**

`power`, `glm`, `family`.

**Examples**

```r
utils::str(make.link("logit"))
```

---

**makepredictcall**

Utility Function for Safe Prediction

**Description**

A utility to help `model.frame.default` create the right matrices when predicting from models with terms like (univariate) `poly` or `ns`.

**Usage**

```r
makepredictcall(var, call)
```
Arguments

var  A variable.
call  The term in the formula, as a call.

Details

This is a generic function with methods for poly, bs and ns: the default method handles scale. If model.frame.default encounters such a term when creating a model frame, it modifies the predvars attribute of the terms supplied by replacing the term with one which will work for predicting new data. For example makepredictcall ns adds arguments for the knots and intercept.

To make use of this, have your model-fitting function return the terms attribute of the model frame, or copy the predvars attribute of the terms attribute of the model frame to your terms object.

To extend this, make sure the term creates variables with a class, and write a suitable method for that class.

Value

A replacement for call for the predvars attribute of the terms.

See Also

model.frame, poly, scale; bs and ns in package splines.
cars for an example of prediction from a polynomial fit.

Examples

```r
require(graphics)

## using poly: this did not work in R < 1.5.0
fm <- lm(weight ~ poly(height, 2), data = women)
plot(women, xlab = "Height (in)", ylab = "Weight (lb)"
ht <- seq(57, 73, len = 200)
lines(ht, predict(fm, data.frame(height = ht)))

## see also example(cars)

## see bs and ns for spline examples.
```

Description

A class for the multivariate analysis of variance.

Usage

manova(...)

Arguments

...  Arguments to be passed to aov.
Details

Class "manova" differs from class "aov" in selecting a different summary method. Function manova calls aov and then add class "manova" to the result object for each stratum.

Value

See aov and the comments in ‘Details’ here.

References

See Also

aov, summary.manova, the latter containing examples.

Examples

```r
## Set orthogonal contrasts.
op <- options(contrasts = c("contr.helmert", "contr.poly"))

## Fake a 2nd response variable
npk2 <- within(npk, foo <- rnorm(24))
( npk2.aov <- manova(cbind(yield, foo) ~ block + N*P*K, npk2) )
summary(npk2.aov)

( npk2.aovE <- manova(cbind(yield, foo) ~ N*P*K + Error(block), npk2) )
summary(npk2.aovE)
```

Description

Performs a Cochran-Mantel-Haenszel chi-squared test of the null that two nominal variables are conditionally independent in each stratum, assuming that there is no three-way interaction.

Usage

```r
mantelhaen.test(x, y = NULL, z = NULL,
    alternative = c("two.sided", "less", "greater"),
    correct = TRUE, exact = FALSE, conf.level = 0.95)
```
Arguments

\textbf{x} \quad \text{either a 3-dimensional contingency table in array form where each dimension is at least 2 and the last dimension corresponds to the strata, or a factor object with at least 2 levels.}

\textbf{y} \quad \text{a factor object with at least 2 levels; ignored if \textbf{x} is an array.}

\textbf{z} \quad \text{a factor object with at least 2 levels identifying to which stratum the corresponding elements in \textbf{x} and \textbf{y} belong; ignored if \textbf{x} is an array.}

\textbf{alternative} \quad \text{indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the 2 by 2 by \textit{K} case.}

\textbf{correct} \quad \text{a logical indicating whether to apply continuity correction when computing the test statistic. Only used in the 2 by 2 by \textit{K} case.}

\textbf{exact} \quad \text{a logical indicating whether the Mantel-Haenszel test or the exact conditional test (given the strata margins) should be computed. Only used in the 2 by 2 by \textit{K} case.}

\textbf{conf.level} \quad \text{confidence level for the returned confidence interval. Only used in the 2 by 2 by \textit{K} case.}

Details

If \textbf{x} is an array, each dimension must be at least 2, and the entries should be nonnegative integers. \textsc{NA}'s are not allowed. Otherwise, \textbf{x}, \textbf{y} and \textbf{z} must have the same length. Triples containing \textsc{NA}'s are removed. All variables must take at least two different values.

Value

A list with class "htest" containing the following components:

\textbf{statistic} \quad \text{Only present if no exact test is performed. In the classical case of a 2 by 2 by \textit{K} table (i.e., of dichotomous underlying variables), the Mantel-Haenszel chi-squared statistic; otherwise, the generalized Cochran-Mantel-Haenszel statistic.}

\textbf{parameter} \quad \text{the degrees of freedom of the approximate chi-squared distribution of the test statistic (1 in the classical case). Only present if no exact test is performed.}

\textbf{p.value} \quad \text{the p-value of the test.}

\textbf{conf.int} \quad \text{a confidence interval for the common odds ratio. Only present in the 2 by 2 by \textit{K} case.}

\textbf{estimate} \quad \text{an estimate of the common odds ratio. If an exact test is performed, the conditional Maximum Likelihood Estimate is given; otherwise, the Mantel-Haenszel estimate. Only present in the 2 by 2 by \textit{K} case.}

\textbf{null.value} \quad \text{the common odds ratio under the null of independence, 1. Only present in the 2 by 2 by \textit{K} case.}

\textbf{alternative} \quad \text{a character string describing the alternative hypothesis. Only present in the 2 by 2 by \textit{K} case.}

\textbf{method} \quad \text{a character string indicating the method employed, and whether or not continuity correction was used.}

\textbf{data.name} \quad \text{a character string giving the names of the data.}
Note

The asymptotic distribution is only valid if there is no three-way interaction. In the classical 2 by 2 by $K$ case, this is equivalent to the conditional odds ratios in each stratum being identical. Currently, no inference on homogeneity of the odds ratios is performed.

See also the example below.

## This suggests that the assumption of homogeneous (conditional)
## odds ratios may be violated. The traditional approach would be
## using the Woolf test for interaction:
woolf <- function(x) {
  x <- x + 1 / 2
  k <- dim(x)[3]
  w <- apply(x, 3, function(x) 1 / sum(1 / x))
  1 - pchisq(sum(w * (log(or) - weighted.mean(log(or), w)) ^ 2), k - 1)
```
mauchly.test

Mauchly's Test of Sphericity

Description
Tests whether a Wishart-distributed covariance matrix (or transformation thereof) is proportional to a given matrix.

Usage
mauchly.test(object, ...)  
## S3 method for class 'mlm'
mauchly.test(object, ...)  
## S3 method for class 'SSD'
mauchly.test(object, Sigma = diag(nrow = p),  
T = Thin.row(proj(M) - proj(X)), M = diag(nrow = p), X = ~0,  
idata = data.frame(index = seq_len(p)), ...)

Arguments

object
object of class SSD or mlm.
Sigma
matrix to be proportional to.
T
transformation matrix. By default computed from M and X.
M
formula or matrix describing the outer projection (see below).
X
formula or matrix describing the inner projection (see below).
idata
data frame describing intra-block design.
...
arguments to be passed to or from other methods.
Details

Mauchly’s test test for whether a covariance matrix can be assumed to be proportional to a given matrix.

This is a generic function with methods for classes "mlm" and "SSD".

The basic method is for objects of class SSD the method for mlm objects just extracts the SSD matrix and invokes the corresponding method with the same options and arguments.

The T argument is used to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A matrix T can be given directly or specified as the difference between two projections onto the spaces spanned by M and X, which in turn can be given as matrices or as model formulas with respect to idata (the tests will be invariant to parametrization of the quotient space M/X).

The common use of this test is in repeated measurements designs, with $X = -1$. This is almost, but not quite the same as testing for compound symmetry in the untransformed covariance matrix.

Notice that the defaults involve p, which is calculated internally as the dimension of the SSD matrix, and a couple of hidden functions in the stats namespace, namely proj which calculates projection matrices from design matrices or model formulas and thin.row which removes linearly dependent rows from a matrix until it has full row rank.

Value

An object of class "htest"

Note

The p-value differs slightly from that of SAS because a second order term is included in the asymptotic approximation in R.

References

mauchly.test(mlmfit, X = -1)

### tests using intra-subject 3x2 design
idata <- data.frame(deg = gl(3, 1, 6, labels = c(0, 4, 8)),
                      noise = gl(2, 3, 6, labels = c("A","P")))
mauchly.test(mlmfit, X = ~ deg + noise, idata = idata)
mauchly.test(mlmfit, M = ~ deg + noise, X = ~ noise, idata = idata)
```
mcnemar.test  McNemar’s Chi-squared Test for Count Data

Description

Performs McNemar’s chi-squared test for symmetry of rows and columns in a two-dimensional contingency table.

Usage

mcnemar.test(x, y = NULL, correct = TRUE)

Arguments

x  either a two-dimensional contingency table in matrix form, or a factor object.
y  a factor object; ignored if x is a matrix.
correct  a logical indicating whether to apply continuity correction when computing the test statistic.

Details

The null is that the probabilities of being classified into cells $[i, j]$ and $[j, i]$ are the same.

If x is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both x and y must be vectors or factors of the same length. Incomplete cases are removed, vectors are coerced into factors, and the contingency table is computed from these.

Continuity correction is only used in the 2-by-2 case if correct is TRUE.

Value

A list with class "htest" containing the following components:

statistic  the value of McNemar’s statistic.
parameter  the degrees of freedom of the approximate chi-squared distribution of the test statistic.
p.value  the p-value of the test.
method  a character string indicating the type of test performed, and whether continuity correction was used.
data.name  a character string giving the name(s) of the data.

References

Examples

```r
## Presidential Approval Ratings.
## Approval of the President's performance in office in two surveys,
## one month apart, for a random sample of 1500 voting-age Americans.
Performance <-
  matrix(c(794, 86, 150, 570),
         nrow = 2,
         dimnames = list("1st Survey" = c("Approve", "Disapprove"),
                        "2nd Survey" = c("Approve", "Disapprove"))
  Performance
mcnemar.test(Performance)
## => significant change (in fact, drop) in approval ratings
```

Description

Compute the sample median.

Usage

```r
median(x, na.rm = FALSE)
```

Arguments

- `x` - an object for which a method has been defined, or a numeric vector containing
  the values whose median is to be computed.
- `na.rm` - a logical value indicating whether NA values should be stripped before the
  computation proceeds.

Details

This is a generic function for which methods can be written. However, the default method makes
use of is.na, sort and mean from package base all of which are generic, and so the default method
will work for most classes (e.g., "Date") for which a median is a reasonable concept.

Value

The default method returns a length-one object of the same type as `x`, except when `x` is integer of
even length, when the result will be double.

If there are no values or if `na.rm = FALSE` and there are NA values the result is NA of the same type
as `x` (or more generally the result of `x[!is.na(x)][na]`).

medpolish

\textit{Median Polish of a Matrix}

Description

Fits an additive model using Tukey’s \textit{median polish} procedure.

Usage

\[
\text{medpolish}(x, \text{eps} = 0.01, \text{maxiter} = 10, \text{trace.iter} = \text{TRUE},
\]
\[
\text{na.rm} = \text{FALSE})
\]

Arguments

- \textbf{x} : a numeric matrix.
- \textbf{eps} : real number greater than 0. A tolerance for convergence: see ‘Details’.
- \textbf{maxiter} : the maximum number of iterations
- \textbf{trace.iter} : logical. Should progress in convergence be reported?
- \textbf{na.rm} : logical. Should missing values be removed?

Details

The model fitted is additive (constant + rows + columns). The algorithm works by alternately removing the row and column medians, and continues until the proportional reduction in the sum of absolute residuals is less than \text{eps} or until there have been \text{maxiter} iterations. The sum of absolute residuals is printed at each iteration of the fitting process, if \text{trace.iter} is \text{TRUE}. If \text{na.rm} is \text{FALSE} the presence of any NA value in \text{x} will cause an error, otherwise NA values are ignored.

\text{medpolish} returns an object of class \text{medpolish} (see below). There are printing and plotting methods for this class, which are invoked via the generics \text{print} and \text{plot}.

Value

An object of class \text{medpolish} with the following named components:

- \text{overall} : the fitted constant term.
- \text{row} : the fitted row effects.
- \text{col} : the fitted column effects.
- \text{residuals} : the residuals.
- \text{name} : the name of the dataset.

   med.d$overall + outer(med.d$row,med.d$col, "+") + med.d$residuals)
```

---

model.extract

Extract Components from a Model Frame

Description

Returns the response, offset, subset, weights or other special components of a model frame passed as optional arguments to model.frame.

Usage

```r
model.extract(frame, component)
model.offset(x)
model.response(data, type = "any")
model.weights(x)
```

Arguments

- `frame`, `x`, `data` A model frame.
- `component` literal character string or name. The name of a component to extract, such as "weights","subset".
- `type` One of "any", "numeric", "double". Using either of latter two coerces the result to have storage mode "double".
model.frame

Details

model.extract is provided for compatibility with S, which does not have the more specific functions. It is also useful to extract e.g. the etastart and mustart components of a glm fit.

model.offset and model.response are equivalent to model.extract(, "offset") and model.extract(, "response") respectively. model.offset sums any terms specified by offset terms in the formula or by offset arguments in the call producing the model frame: it does check that the offset is numeric.

model.weights is slightly different from model.frame(, "weights") in not naming the vector it returns.

Value

The specified component of the model frame, usually a vector.

See Also

model.frame, offset

Examples

```r
a <- model.frame(cbind(ncases, ncontrols) ~ agegp + tobgp + alcgp, data = esoph)
model.extract(a, "response")
stopifnot(model.extract(a, "response") == model.response(a))

a <- model.frame(ncases/(ncases+ncontrols) ~ agegp + tobgp + alcgp,
data = esoph, weights = ncases+ncontrols)
model.response(a)
model.extract(a, "weights")

a <- model.frame(cbind(ncases, ncontrols) ~ agegp,
                 something = tobgp, data = esoph)
names(a)
stopifnot(model.extract(a, "something") == esoph$tobgp)
```

model.frame

Extracting the Model Frame from a Formula or Fit

Description

model.frame (a generic function) and its methods return a data.frame with the variables needed to use formula and any ... arguments.

Usage

model.frame(formula, ...

## Default S3 method:
model.frame(formula, data = NULL,
            subset = NULL, na.action = na.fail,
            drop.unused.levels = FALSE, xlev = NULL, ...)
## model.frame

```r
## S3 method for class 'aovlist'
model.frame(formula, data = NULL, ...)

## S3 method for class 'glm'
model.frame(formula, ...)

## S3 method for class 'lm'
model.frame(formula, ...)

get_all_vars(formula, data, ...)
```

### Arguments

- **formula**: a model `formula` or `terms` object or an R object.
- **data**: a data.frame, list or environment (or object coercible by `as.data.frame` to a data.frame), containing the variables in `formula`. Neither a matrix nor an array will be accepted.
- **subset**: a specification of the rows to be used: defaults to all rows. This can be any valid indexing vector (see [.data.frame) for the rows of data or if that is not supplied, a data frame made up of the variables used in `formula`.
- **na.action**: how NAs are treated. The default is first, any `na.action` attribute of `data`, second a `na.action` setting of `options`, and third `na.fail` if that is unset. The ‘factory-fresh’ default is `na.omit`. Another possible value is `NULL`.
- **drop.unused.levels**: should factors have unused levels dropped? Defaults to `FALSE`.
- **xlev**: a named list of character vectors giving the full set of levels to be assumed for each factor.
- **...**: further arguments such as `data`, `na.action`, `subset`. Any additional arguments such as `offset` and `weights` which reach the default method are used to create further columns in the model frame, with parenthesised names such as "(offset)".

### Details

Exactly what happens depends on the class and attributes of the object `formula`. If this is an object of fitted-model class such as "lm", the method will either return the saved model frame used when fitting the model (if any, often selected by argument `model = TRUE`) or pass the call used when fitting on to the default method. The default method itself can cope with rather standard model objects such as those of class "lm" from package MASS if no other arguments are supplied.

The rest of this section applies only to the default method.

If either `formula` or `data` is already a model frame (a data frame with a "terms" attribute) and the other is missing, the model frame is returned. Unless `formula` is a terms object, `as.formula` and then `terms` is called on it. (If you wish to use the `keep.order` argument of `terms.formula, pass a terms object rather than a formula.)

Row names for the model frame are taken from the `data` argument if present, then from the names of the response in the `formula` (or rownames if it is a matrix), if there is one.

All the variables in `formula`, `subset` and in `...` are looked for first in `data` and then in the environment of `formula` (see the help for `formula()` for further details) and collected into a data frame. Then the `subset` expression is evaluated, and it is used as a row index to the data frame. Then the `na.action` function is applied to the data frame (and may well add attributes). The levels of any
factors in the data frame are adjusted according to the drop.unused.levels and xlev arguments: if xlev specifies a factor and a character variable is found, it is converted to a factor (as from R 2.10.0).

Unless na.action = NULL, time-series attributes will be removed from the variables found (since they will be wrong if NAs are removed).

Note that all the variables in the formula are included in the data frame, even those preceded by ~. Only variables whose type is raw, logical, integer, real, complex or character can be included in a model frame: this includes classed variables such as factors (whose underlying type is integer), but excludes lists.

get_all_vars returns a data.frame containing the variables used in formula plus those specified .... Unlike model.frame.default, it returns the input variables and not those resulting from function calls in formula.

Value

A data.frame containing the variables used in formula plus those specified in .... It will have additional attributes, including "terms" for an object of class "terms" derived from formula, and possibly "na.action" giving information on the handling of NAs (which will not be present if no special handling was done, e.g. by na.pass).

References

See Also

model.matrix for the 'design matrix', formula for formulas and expand.model.frame for model.frame manipulation.

Examples

data.class(model.frame(dist ~ speed, data = cars))
model.matrix

Arguments

object       an object of an appropriate class. For the default method, a model formula or a
terms object.
data         a data frame created with model.frame. If another sort of object, model.frame
             is called first.
contrasts.arg A list, whose entries are values (numeric matrices or character strings naming
             functions) to be used as replacement values for the contrasts replacement
             function and whose names are the names of columns of data containing
             factors.
xlev         to be used as argument of model.frame if data is such that model.frame is
called.
...          further arguments passed to or from other methods.

Details

model.matrix creates a design matrix from the description given in terms(object), using the
data in data which must supply variables with the same names as would be created by a call to
model.frame(object) or, more precisely, by evaluating attr(terms(object), "variables").
If data is a data frame, there may be other columns and the order of columns is not important. Any
character variables are coerced to factors. After coercion, all the variables used on the right-hand
side of the formula must be logical, integer, numeric or factor.

If contrasts.arg is specified for a factor it overrides the default factor coding for that variable and
any "contrasts" attribute set by C or contrasts.

In an interaction term, the variable whose levels vary fastest is the first one to appear in the formula
(and not in the term), so in ~ a * b * b:a the interaction will have a varying fastest.

By convention, if the response variable also appears on the right-hand side of the formula it is
dropped (with a warning), although interactions involving the term are retained.

Value

The design matrix for a regression-like model with the specified formula and data.

There is an attribute "assign", an integer vector with an entry for each column in the matrix giving
the term in the formula which gave rise to the column. Value 0 corresponds to the intercept (if any),
and positive values to terms in the order given by the term.labels attribute of the terms structure
 corresponding to object.

If there are any factors in terms in the model, there is an attribute "contrasts", a named list with an
entry for each factor. This specifies the contrasts that would be used in terms in which the factor is
coded by contrasts (in some terms dummy coding may be used), either as a character vector naming
a function or as a numeric matrix.

Examples
ff <- log(Volume) ~ log(Height) + log(Girth)
utils::str(m <- model.frame(ff, trees))
mat <- model.matrix(ff, m)

dd <- data.frame(a = gl(3,4), b = gl(4,1,12)) # balanced 2-way
options("contrasts")
model.matrix(~ a + b, dd)
model.matrix(~ a + b, dd, contrasts = list(a = "contr.sum"))
model.matrix(~ a + b, dd, contrasts = list(a = "contr.sum", b = "contr.poly"))
m.orth <- model.matrix(~a+b, dd, contrasts = list(a = "contr.helmert"))
crossprod(m.orth) # m.orth is ALMOST orthogonal

Description
Computes summary tables for model fits, especially complex aov fits.

Usage
model.tables(x, ...)  
## S3 method for class 'aov'
model.tables(x, type = "effects", se = FALSE, cterms, ...)
## S3 method for class 'aovlist'
model.tables(x, type = "effects", se = FALSE, ...)

Arguments
x a model object, usually produced by aov

Some additional arguments:

type type of table: currently only "effects" and "means" are implemented.

se should standard errors be computed?

cterms A character vector giving the names of the terms for which tables should be computed. The default is all tables.

... further arguments passed to or from other methods.

Details
For type = "effects" give tables of the coefficients for each term, optionally with standard errors.

For type = "means" give tables of the mean response for each combinations of levels of the factors in a term.

The "aov" method cannot be applied to components of a "aovlist" fit.
Value

An object of class "tables.aov", as list which may contain components

- **tables**: A list of tables for each requested term.
- **n**: The replication information for each term.
- **se**: Standard error information.

Warning

The implementation is incomplete, and only the simpler cases have been tested thoroughly.
Weighted aov fits are not supported.

See Also

* aov, proj.replications, TukeyHSD, se.contrast

Examples

```r
options(contrasts = c("contr.helmert", "contr.treatment"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
model.tables(npk.aov, "means", se = TRUE)

## as a test, not particularly sensible statistically
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
model.tables(npk.aovE, se = TRUE)
model.tables(npk.aovE, "means")
```

---

**monthplot**

- **Plot a Seasonal or other Subseries from a Time Series**

Description

These functions plot seasonal (or other) subseries of a time series. For each season (or other category), a time series is plotted.

Usage

- `monthplot(x, ...)`
- ```r
  ## S3 method for class 'stl'
  monthplot(x, labels = NULL, ylab = choice, choice = "seasonal",...)
  ```
- ```r
  ## S3 method for class 'StructTS'
  monthplot(x, labels = NULL, ylab = choice, choice = "sea",...)
  ```
- ```r
  ## S3 method for class 'ts'
  monthplot(x, labels = NULL, times = time(x), phase = cycle(x),
  ylab = deparse(substitute(x)),...)
  ```
- ```r
  ## Default S3 method:
  ```
monthplot(x, labels = 1L:12L,
... ylab = deparse(substitute(x)),
times = seq_along(x),
phase = (times - 1L)%*%length(labels) + 1L, base = mean,
axes = TRUE, type = c("l", "h"), box = TRUE,
add = FALSE,
col = par("col"), lty = par("lty"), lwd = par("lwd"),
col.base = col, lty.base = lty, lwd.base = lwd, ...)

Arguments

x Time series or related object.
labels Labels to use for each ‘season’.
ylab y label.
times Time of each observation.
phase Indicator for each ‘season’.
base Function to use for reference line for subseries.
choice Which series of an stl or StructTS object?
... Arguments to be passed to the default method or graphical parameters.
axes Should axes be drawn (ignored if add = TRUE)?
type Type of plot. The default is to join the points with lines, and "h" is for histogram-like vertical lines.
box Should a box be drawn (ignored if add = TRUE)?
add Should thus just add on an existing plot.
col, lty, lwd Graphics parameters for the series.
col.base, lty.base, lwd.base Graphics parameters for the segments used for the reference lines.

Details

These functions extract subseries from a time series and plot them all in one frame. The ts, stl, and StructTS methods use the internally recorded frequency and start and finish times to set the scale and the seasons. The default method assumes observations come in groups of 12 (though this can be changed).

If the labels are not given but the phase is given, then the labels default to the unique values of the phase. If both are given, then the phase values are assumed to be indices into the labels array, i.e., they should be in the range from 1 to length(labels).

Value

These functions are executed for their side effect of drawing a seasonal subseries plot on the current graphical window.

mood.test

Mood Two-Sample Test of Scale

Description

Performs Mood’s two-sample test for a difference in scale parameters.

Usage

mood.test(x, ...)

## Default S3 method:
mood.test(x, y,
  alternative = c("two.sided", "less", "greater"), ...)

## S3 method for class 'formula'
mood.test(formula, data, subset, na.action, ...)

Arguments

x, y numeric vectors of data values.

alternative indicates the alternative hypothesis and must be one of "two.sided" (default), "greater" or "less" all of which can be abbreviated.

formula a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.

data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset  

an optional vector specifying a subset of observations to be used.

na.action  
a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.

...  
further arguments to be passed to or from methods.

Details

The underlying model is that the two samples are drawn from \( f(x - l) \) and \( f((x - l)/s)/s \), respectively, where \( l \) is a common location parameter and \( s \) is a scale parameter.

The null hypothesis is \( s = 1 \).

There are more useful tests for this problem.

In the case of ties, the formulation of Mielke (1967) is employed.

Value

A list with class "htest" containing the following components:

- **statistic**  
  the value of the test statistic.

- **p.value**  
  the p-value of the test.

- **alternative**  
  a character string describing the alternative hypothesis.

- **method**  
  the character string "Mood two-sample test of scale".

- **data.name**  
  a character string giving the names of the data.

Examples

```r
## Same data as for the Ansari-Bradley test:
## Serum iron determination using Hyland control sera
mood.test(ramsay, jung.parekh)
## Compare this to ansari.test(ramsay, jung.parekh)
```
The Multinomial Distribution

Description

Generate multinomially distributed random number vectors and compute multinomial probabilities.

Usage

\[
\text{rmultinom}(n, \text{size}, \text{prob}) \\
\text{dmultinom}(x, \text{size} = \text{NULL}, \text{prob}, \text{log} = \text{FALSE})
\]

Arguments

- \(x\): vector of length \(K\) of integers in \(0:\text{size}\).
- \(n\): number of random vectors to draw.
- \(\text{size}\): integer, say \(N\), specifying the total number of objects that are put into \(K\) boxes in the typical multinomial experiment. For \(\text{dmultinom}\), it defaults to \(\sum(x)\).
- \(\text{prob}\): numeric non-negative vector of length \(K\), specifying the probability for the \(K\) classes; is internally normalized to sum 1. Infinite and missing values are not allowed.
- \(\text{log}\): logical; if \(\text{TRUE}\), log probabilities are computed.

Details

If \(x\) is a \(K\)-component vector, \(\text{dmultinom}(x, \text{prob})\) is the probability

\[
P(X_1 = x_1, \ldots, X_K = x_K) = C \times \prod_{j=1}^{K} \pi_j^{x_j}
\]

where \(C\) is the ‘multinomial coefficient’ \(C = N!/(x_1! \cdots x_K!)\) and \(N = \sum_{j=1}^{K} x_j\).

By definition, each component \(X_j\) is binomially distributed as Bin(\(n_j, \pi_j\)) for \(j = 1, \ldots, K\).

The \(\text{rmultinom}()\) algorithm draws binomials \(X_j\) from Bin(\(n_j, P_j\)) sequentially, where \(n_1 = N\) (\(N := \text{size}\), \(P_1 = \pi_1\) (\(\pi\) is prob scaled to sum 1), and for \(j \geq 2\), recursively, \(n_j = N - \sum_{k=1}^{j-1} X_k\) and \(P_j = \pi_j/(1 - \sum_{k=1}^{j-1} \pi_k)\).

Value

For \(\text{rmultinom}()\), an integer \(K \times n\) matrix where each column is a random vector generated according to the desired multinomial law, and hence summing to \(\text{size}\). Whereas the transposed result would seem more natural at first, the returned matrix is more efficient because of columnwise storage.

Note

\(\text{dmultinom}\) is currently not vectorized at all and has no C interface (API); this may be amended in the future.
See Also

Distributions for standard distributions, including \texttt{dbinom} which is a special case conceptually.

Examples

\begin{verbatim}
rmultinom(10, size = 12, prob = c(0.1,0.2,0.8))
pr <- c(1,3,6,10) # normalization not necessary for generation
rmultinom(10, rep(20, length(pr)), prob = pr)

# all possible outcomes of Multinom(N = 3, K = 3)
X <- t(as.matrix(expand.grid(0:3, 0:3)));
X <- X[, colSums(X) <= 3]
X <- rbind(X[, 3:3 - colSums(X)]; dimnames(X) <- list(letters[1:3], NULL)
X
round(apply(X, 2, function(x) dmultinom(x, prob = c(1,2,5)), 3)
\end{verbatim}
na.contiguous

Find Longest Contiguous Stretch of non-NAs

Description
Find the longest consecutive stretch of non-missing values in a time series object. (In the event of a tie, the first such stretch.)

Usage
na.contiguous(object, ...)

Arguments
object a univariate or multivariate time series.
... further arguments passed to or from other methods.

Value
A time series without missing values. The class of object will be preserved.

See Also
na.omit and na.omit.ts; na.fail

Examples
na.contiguous(presidents)

na.fail
Handle Missing Values in Objects

Description
These generic functions are useful for dealing with NAs in e.g., data frames. na.fail returns the object if it does not contain any missing values, and signals an error otherwise. na.omit returns the object with incomplete cases removed. na.pass returns the object unchanged.

Usage
na.fail(object, ...)
na.omit(object, ...)
na.exclude(object, ...)
na.pass(object, ...)

Arguments
object an R object, typically a data frame
... further arguments special methods could require.
Details

At present these will handle vectors, matrices and data frames comprising vectors and matrices (only).

If na.omit removes cases, the row numbers of the cases form the "na.action" attribute of the result, of class "omit".

na.exclude differs from na.omit only in the class of the "na.action" attribute of the result, which is "exclude". This gives different behaviour in functions making use of naresid and napredict: when na.exclude is used the residuals and predictions are padded to the correct length by inserting NAs for cases omitted by na.exclude.

References

See Also

na.action, options with argument na.action for setting NA actions; and lm and glm for functions using these. na.contiguous as alternative for time series.

Examples

DF <- data.frame(x = c(1, 2, 3), y = c(0, 10, NA))
na.omit(DF)
m <- as.matrix(DF)
na.omit(m)
stopifnot(all(na.omit(1:3) == 1:3)) # does not affect objects with no NA's
try(na.fail(DF)) #> Error: missing values in ...

options("na.action")

Description

Use missing value information to report the effects of an na.action.

Usage

naprint(x, ...)

Arguments

x An object produced by an na.action function.

... further arguments passed to or from other methods.

Details

This is a generic function, and the exact information differs by method. naprint.omit reports the number of rows omitted: naprint.default reports an empty string.
naresid

Value

A character string providing information on missing values, for example the number.

---

naresid Adjust for Missing Values

Description

Use missing value information to adjust residuals and predictions.

Usage

naresid(omit, x, ...)
napredict(omit, x, ...)

Arguments

omit an object produced by an na.action function, typically the “na.action” attribute of the result of na.omit or na.exclude.
x a vector, data frame, or matrix to be adjusted based upon the missing value information.
... further arguments passed to or from other methods.

Details

These are utility functions used to allow predict, fitted and residuals methods for modelling functions to compensate for the removal of NAs in the fitting process. They are used by the default, "lm", "glm" and "nls" methods, and by further methods in packages MASS, rpart and survival. Also used for the scores returned by factanal, prcomp and princomp.

The default methods do nothing. The default method for the na.exclude action is to pad the object with NAs in the correct positions to have the same number of rows as the original data frame.

Currently naresid and napredict are identical, but future methods need not be. naresid is used for residuals, and napredict for fitted values, predictions and weights.

Value

These return a similar object to x.

Note

In the early 2000s, packages rpart and survival contained versions of these functions that had an na.omit action equivalent to that now used for na.exclude.
NegBinomial

The Negative Binomial Distribution

Description
Density, distribution function, quantile function and random generation for the negative binomial distribution with parameters size and prob.

Usage

- `dnbinom(x, size, prob, mu, log = FALSE)`
- `pnbinom(q, size, prob, mu, lower.tail = TRUE, log.p = FALSE)`
- `qnbinom(p, size, prob, mu, lower.tail = TRUE, log.p = FALSE)`
- `rnbinom(n, size, prob, mu)`

Arguments
- `x`: vector of (non-negative integer) quantiles.
- `q`: vector of quantiles.
- `p`: vector of probabilities.
- `n`: number of observations. If length(n) > 1, the length is taken to be the number required.
- `size`: target for number of successful trials, or dispersion parameter (the shape parameter of the gamma mixing distribution). Must be strictly positive, need not be integer.
- `prob`: probability of success in each trial. 0 < prob <= 1.
- `mu`: alternative parametrization via mean: see ‘Details’.
- `log`, `log.p`: logical; if TRUE, probabilities p are given as log(p).
- `lower.tail`: logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details
The negative binomial distribution with size = n and prob = p has density
\[
p(x) = \frac{\Gamma(x + n)}{\Gamma(n)x!} p^n (1 - p)^x
\]
for \( x = 0, 1, 2, \ldots, n > 0 \) and \( 0 < p \leq 1 \).

This represents the number of failures which occur in a sequence of Bernoulli trials before a target number of successes is reached. The mean is \( n(1 - p)/p \) and variance \( n(1 - p)/p^2 \).

A negative binomial distribution can also arise as a mixture of Poisson distributions with mean distributed as a gamma distribution (see `pgamma`) with scale parameter \( (1 - \text{prob})/\text{prob} \) and shape parameter size. (This definition allows non-integer values of size.)

An alternative parametrization (often used in ecology) is by the mean mu, and size, the dispersion parameter, where prob = size/(size+mu). The variance is mu + mu^2/size in this parametrization.

If an element of x is not integer, the result of `dnbinom` is zero, with a warning.
The case size == 0 is the distribution concentrated at zero. This is the limiting distribution for size approaching zero, even if mu rather than prob is held constant. Notice though, that the mean of the limit distribution is 0, whatever the value of mu.

The quantile is defined as the smallest value x such that F(x) ≥ p, where F is the distribution function.

Value

dnbinom gives the density, pbinom gives the distribution function, qbinom gives the quantile function, and rbinom generates random deviates.

Invalid size or prob will result in return value NaN, with a warning.

The length of the result is determined by n for rbinom, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Source

dnbinom computes via binomial probabilities, using code contributed by Catherine Loader (see dbinom).
pbinom uses pbeta.
qbinom uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.
rbinom uses the derivation as a gamma mixture of Poissons, see

See Also

Distributions for standard distributions, including dbinom for the binomial, dpois for the Poisson and dgeom for the geometric distribution, which is a special case of the negative binomial.

Examples

require(graphics)
x <- 0:11
dnbinom(x, size = 1, prob = 1/2) * 2^(1 + x) # == 1
126 / dnbinom(0:8, size = 2, prob = 1/2) # theoretically integer

## Cumulative ('p') = Sum of discrete prob.s ('d'); Relative error : summary(1 - cumsum(dbinom(x, size = 2, prob = 1/2))) / pbinom(x, size = 2, prob = 1/2))
x <- 0:15
size <- (1:20)/4
persp(x, size, dnb <- outer(x, size, function(x,s) dnbinom(x, s, prob = 0.4)), xlab = "x", ylab = "s", zlab = "density", theta = 150)
title(tit <- "negative binomial density(x,s, pr = 0.4) vs. x & s")
image (x, size, log10(dnb), main = paste("log ", tit, "]")
contour(x, size, log10(dnb), add = TRUE)
## Alternative parametrization

```r
x1 <- rbinom(500, mu = 4, size = 1)
x2 <- rbinom(500, mu = 4, size = 10)
x3 <- rbinom(500, mu = 4, size = 100)
h1 <- hist(x1, breaks = 20, plot = FALSE)
h2 <- hist(x2, breaks = h1$breaks, plot = FALSE)
h3 <- hist(x3, breaks = h1$breaks, plot = FALSE)
barplot(rbind(h1$counts, h2$counts, h3$counts),
       beside = TRUE, col = c("red","blue","cyan"),
       names.arg = round(h1$breaks[-length(h1$breaks)]))
```

---

### nextn

**Highly Composite Numbers**

**Description**

nextn returns the smallest integer, greater than or equal to \( n \), which can be obtained as a product of powers of the values contained in `factors`. nextn is intended to be used to find a suitable length to zero-pad the argument of `fft` so that the transform is computed quickly. The default value for `factors` ensures this.

**Usage**

```r
nextn(n, factors = c(2, 3, 5))
```

**Arguments**

- `n`: an integer.
- `factors`: a vector of positive integer factors.

**See Also**

`convolve`, `fft`.

**Examples**

```r
nextn(1001) # 1024
table(sapply(599:630, nextn))
```

---

### nlm

**Non-Linear Minimization**

**Description**

This function carries out a minimization of the function \( f \) using a Newton-type algorithm. See the references for details.
Usage

\texttt{nlm(f, p, ..., hessian = FALSE, typsize = rep(1, length(p)),}
\texttt{fscale = 1, print.level = 0, ndigit = 12, gradtol = 1e-6,}
\texttt{stepmax = max(1000 * sqrt(sum((p/typsize)^2)), 1000),}
\texttt{steptol = 1e-6, iterlim = 100, check.analiticals = TRUE)}

Arguments

\texttt{f}  
the function to be minimized, returning a single numeric value. This should be
a function with first argument a vector of the length of \texttt{p} followed by any other
arguments specified by the ... argument.

If the function value has an attribute called gradient or both gradient and
hessian attributes, these will be used in the calculation of updated parameter
values. Otherwise, numerical derivatives are used. \texttt{deriv} returns a function with
suitable gradient attribute and optionally a hessian attribute.

\texttt{p}  
starting parameter values for the minimization.

...  
additional arguments to be passed to \texttt{f}.

\texttt{hessian}  
if \texttt{TRUE}, the hessian of \texttt{f} at the minimum is returned.

\texttt{typsize}  
an estimate of the size of each parameter at the minimum.

\texttt{fscale}  
an estimate of the size of \texttt{f} at the minimum.

\texttt{print.level}  
this argument determines the level of printing which is done during the mini-
mization process. The default value of 0 means that no printing occurs, a value
of 1 means that initial and final details are printed and a value of 2 means that
full tracing information is printed.

\texttt{ndigit}  
the number of significant digits in the function \texttt{f}.

\texttt{gradtol}  
a positive scalar giving the tolerance at which the scaled gradient is considered
close enough to zero to terminate the algorithm. The scaled gradient is a measure
of the relative change in \texttt{f} in each direction \texttt{p[i]} divided by the relative change
in \texttt{p[i]}.

\texttt{stepmax}  
a positive scalar which gives the maximum allowable scaled step length.
\texttt{stepmax} is used to prevent steps which would cause the optimization function to
overflow, to prevent the algorithm from leaving the area of interest in parameter
space, or to detect divergence in the algorithm. \texttt{stepmax} would be chosen small
enough to prevent the first two of these occurrences, but should be larger than
any anticipated reasonable step.

\texttt{steptol}  
A positive scalar providing the minimum allowable relative step length.

\texttt{iterlim}  
a positive integer specifying the maximum number of iterations to be performed
before the program is terminated.

\texttt{check.analiticals}  
a logical scalar specifying whether the analytic gradients and Hessians, if they
are supplied, should be checked against numerical derivatives at the initial pa-
rameter values. This can help detect incorrectly formulated gradients or Hess-
ians.

Details

Note that arguments after ... must be matched exactly.
If a gradient or hessian is supplied but evaluates to the wrong mode or length, it will be ignored if `check.analyicals = TRUE` (the default) with a warning. The hessian is not even checked unless the gradient is present and passes the sanity checks.

From the three methods available in the original source, we always use method “1” which is line search.

The functions supplied should always return finite (including not NA and not NaN) values: for the function value itself non-finite values are replaced by the maximum positive value with a warning.

**Value**

A list containing the following components:

- `minimum` the value of the estimated minimum of \( f \).
- `estimate` the point at which the minimum value of \( f \) is obtained.
- `gradient` the gradient at the estimated minimum of \( f \).
- `hessian` the hessian at the estimated minimum of \( f \) (if requested).
- `code` an integer indicating why the optimization process terminated.
  - 1: relative gradient is close to zero, current iterate is probably solution.
  - 2: successive iterates within tolerance, current iterate is probably solution.
  - 3: last global step failed to locate a point lower than `estimate`. Either `estimate` is an approximate local minimum of the function or `step1` is too small.
  - 4: iteration limit exceeded.
  - 5: maximum step size `stepmax` exceeded five consecutive times. Either the function is unbounded below, becomes asymptotic to a finite value from above in some direction or `stepmax` is too small.
- `iterations` the number of iterations performed.

**Source**

The current code is by Saikat DebRoy and the R Core team, using a C translation of Fortran code by Richard H. Jones.

**References**

**See Also**

- `optim` and `nlminb`.
- `constrOptim` for constrained optimization, `optimize` for one-dimensional minimization and `uniroot` for root finding. `deriv` to calculate analytical derivatives.

For nonlinear regression, `nls` may be better.
Examples

```r
f <- function(x) sum((x-1:length(x))^2)
nlm(f, c(10,10))
nlm(f, c(10,10), print.level = 2)
utils::str(nlm(f, c(5), hessian = TRUE))
```

```r
f <- function(x, a) sum((x-a)^2)
nlm(f, c(10,10), a = c(3,5))
f <- function(x, a)
{
  res <- sum((x-a)^2)
  attr(res, "gradient") <- 2*(x-a)
  res
}
nlm(f, c(10,10), a = c(3,5))
```

```r
## more examples, including the use of derivatives.
## Not run: demo(nlm)
```

---

**nlminb**  
*Optimization using PORT routines*

**Description**

Unconstrained and box-constrained optimization using PORT routines. For historical compatibility.

**Usage**

```r
nlminb(start, objective, gradient = NULL, hessian = NULL, ...,
scale = 1, control = list(), lower = -Inf, upper = Inf)
```

**Arguments**

- `start`  
  numeric vector, initial values for the parameters to be optimized.

- `objective`  
  Function to be minimized. Must return a scalar value. The first argument to `objective` is the vector of parameters to be optimized, whose initial values are supplied through `start`. Further arguments (fixed during the course of the optimization) to `objective` may be specified as well (see `...`).

- `gradient`  
  Optional function that takes the same arguments as `objective` and evaluates the gradient of `objective` at its first argument. Must return a vector as long as `start`.

- `hessian`  
  Optional function that takes the same arguments as `objective` and evaluates the hessian of `objective` at its first argument. Must return a square matrix of order `length(start)`. Only the lower triangle is used.

- `...`  
  Further arguments to be supplied to `objective`.

- `scale`  
  See PORT documentation (or leave alone).

- `control`  
  A list of control parameters. See below for details.

- `lower, upper`  
  vectors of lower and upper bounds, replicated to be as long as `start`. If unspecified, all parameters are assumed to be unconstrained.
Details

Any names of start are passed on to objective and where applicable, gradient and hessian. The parameter vector will be coerced to double.

The parameter vector passed to objective, gradient and hessian had special semantics prior to R 3.1.0 and was shared between calls. The functions should not copy it.

If any of the functions returns NA or NaN the internal code could infinite-loop in R prior to 2.15.2: this is now an error for the gradient and Hessian, and such values for function evaluation are replaced by +Inf with a warning.

Value

A list with components:

- par The best set of parameters found.
- objective The value of objective corresponding to par.
- convergence An integer code. 0 indicates successful convergence.
- message A character string giving any additional information returned by the optimizer, or NULL. For details, see PORT documentation.
- iterations Number of iterations performed.
- evaluations Number of objective function and gradient function evaluations

Control parameters

Possible names in the control list and their default values are:

- eval.max Maximum number of evaluations of the objective function allowed. Defaults to 200.
- iter.max Maximum number of iterations allowed. Defaults to 150.
- trace The value of the objective function and the parameters is printed every trace’th iteration. Defaults to 0 which indicates no trace information is to be printed.
- abs.tol Absolute tolerance. Defaults to 0 so the absolute convergence test is not used. If the objective function is known to be non-negative, the previous default of 1e-20 would be more appropriate.
- rel.tol Relative tolerance. Defaults to 1e-10.
- x.tol X tolerance. Defaults to 1.5e-8.
- xf.tol False convergence tolerance. Defaults to 2.2e-14.
- step.min, step.max Minimum and maximum step size. Both default to 1.
- sing.tol Singular convergence tolerance; defaults to rel.tol.
- scale.init ...
- diff.g an estimated bound on the relative error in the objective function value.

## 25-dimensional box constrained
## par[24] is *not* at boundary
```
nls

Nonlinear Least Squares

Description

Determine the nonlinear (weighted) least-squares estimates of the parameters of a nonlinear model.

Usage

\[
nls(formula, data, start, control, algorithm, trace, subset, weights, na.action, model, lower, upper, \ldots)\]

Arguments

- **formula**: a nonlinear model formula including variables and parameters. Will be coerced to a formula if necessary.
- **data**: an optional data frame in which to evaluate the variables in formula and weights. Can also be a list or an environment, but not a matrix.
- **start**: a named list or named numeric vector of starting estimates. When start is missing, a very cheap guess for start is tried (if algorithm ! = "plinear").
- **control**: an optional list of control settings. See nls.control for the names of the settable control values and their effect.
- **algorithm**: character string specifying the algorithm to use. The default algorithm is a Gauss-Newton algorithm. Other possible values are "plinear" for the Golub-Pereyra algorithm for partially linear least-squares models and "port" for the 'nl2sol' algorithm from the Port library – see the references.
- **trace**: logical value indicating if a trace of the iteration progress should be printed. Default is FALSE. If TRUE the residual (weighted) sum-of-squares and the parameter values are printed at the conclusion of each iteration. When the "plinear" algorithm is used, the conditional estimates of the linear parameters are printed after the nonlinear parameters. When the "port" algorithm is used the objective function value printed is half the residual (weighted) sum-of-squares.
- **subset**: an optional vector specifying a subset of observations to be used in the fitting process.
- **weights**: an optional numeric vector of (fixed) weights. When present, the objective function is weighted least squares.
- **na.action**: a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The ‘factory-fresh’ default is na.omit. Value na.exclude can be useful.
- **model**: logical. If true, the model frame is returned as part of the object. Default is FALSE.
lower, upper vectors of lower and upper bounds, replicated to be as long as start. If unspecified, all parameters are assumed to be unconstrained. Bounds can only be used with the "port" algorithm. They are ignored, with a warning, if given for other algorithms.

... Additional optional arguments. None are used at present.

Details

An nls object is a type of fitted model object. It has methods for the generic functions anova, coef, confint, deviance, df.residual, fitted, formula, logLik, predict, print, profile, residuals, summary, vcov and weights.

Variables in formula (and weights if not missing) are looked for first in data, then the environment of formula and finally along the search path. Functions in formula are searched for first in the environment of formula and then along the search path.

Arguments subset and na.action are supported only when all the variables in the formula taken from data are of the same length: other cases give a warning.

Note that the anova method does not check that the models are nested: this cannot easily be done automatically, so use with care.

Value

A list of

m an nlsModel object incorporating the model.
data the expression that was passed to nls as the data argument. The actual data values are present in the environment of the m component.
call the matched call with several components, notably algorithm.
na.action the "na.action" attribute (if any) of the model frame.
dataClasses the "dataClasses" attribute (if any) of the "terms" attribute of the model frame.
model if model = TRUE, the model frame.
weights if weights is supplied, the weights.
convInfo a list with convergence information.
control the control list used, see the control argument.
convergence, message for an algorithm = "port" fit only, a convergence code (0 for convergence) and message.

To use these is deprecated, as they are available from convInfo now.

Warning

Do not use nls on artificial "zero-residual" data.

The nls function uses a relative-offset convergence criterion that compares the numerical imprecision at the current parameter estimates to the residual sum-of-squares. This performs well on data of the form

\[ y = f(x, \theta) + \epsilon \]

(with \( \text{var}(\epsilon) > 0 \)). It fails to indicate convergence on data of the form

\[ y = f(x, \theta) \]
because the criterion amounts to comparing two components of the round-off error. If you wish to
test nls on artificial data please add a noise component, as shown in the example below.

The algorithm = "port" code appears unfinished, and does not even check that the starting value
is within the bounds. Use with caution, especially where bounds are supplied.

Note

Setting warnOnly = TRUE in the control argument (see nls.control) returns a non-converged
object (since R version 2.5.0) which might be useful for further convergence analysis, but not for
inference.

## alpha and beta vary with Strip. The starting values are provided
## nls.control

Control the Iterations in nls

### Description

Allow the user to set some characteristics of the nls nonlinear least squares algorithm.

### Usage

```r
nls.control(maxiter = 50, tol = 1e-05, minFactor = 1/1024,
             printEval = FALSE, warnOnly = FALSE)
```

### Arguments

- `maxiter`  
  A positive integer specifying the maximum number of iterations allowed.

- `tol`  
  A positive numeric value specifying the tolerance level for the relative offset convergence criterion.

- `minFactor`  
  A positive numeric value specifying the minimum step-size factor allowed on any step in the iteration. The increment is calculated with a Gauss-Newton algorithm and successively halved until the residual sum of squares has been decreased or until the step-size factor has been reduced below this limit.

- `printEval`  
  A logical specifying whether the number of evaluations (steps in the gradient direction taken each iteration) is printed.

- `warnOnly`  
  A logical specifying whether nls() should return instead of signalling an error in the case of termination before convergence. Termination before convergence happens upon completion of maxiter iterations, in the case of a singular gradient, and in the case that the step-size factor is reduced below minFactor.

### Value

A list with exactly five components:

- `maxiter`
- `tol`
- `minFactor`
- `printEval`
- `warnOnly`

with meanings as explained under ‘Arguments’.

---

**NLSstAsymptotic**

*Fit the Asymptotic Regression Model*

**Description**
Fits the asymptotic regression model, in the form $b_0 + b_1 \times (1 - \exp(-\exp(1rc) \times x))$ to the xy data. This can be used as a building block in determining starting estimates for more complicated models.

**Usage**
NLSstAsymptotic(xy)

**Arguments**

* xy a sortedXyData object

**Value**
A numeric value of length 3 with components labelled $b_0$, $b_1$, and $1rc$. $b_0$ is the estimated intercept on the y-axis, $b_1$ is the estimated difference between the asymptote and the y-intercept, and $1rc$ is the estimated logarithm of the rate constant.

**Author(s)**
José Pinheiro and Douglas Bates

**See Also**

**Examples**
Lob.329 <- Loblolly[ Loblolly$Seed == "329", ]
print(NLSstAsymptotic(sortedXyData(expression(age),
expression(height),
Lob.329)), digits = 3)
**NLSstClosestX**

*Inverse Interpolation*

**Description**

Use inverse linear interpolation to approximate the x value at which the function represented by xy is equal to yval.

**Usage**

NLSstClosestX(xy, yval)

**Arguments**

- `xy`: a `sortedXyData` object
- `yval`: a numeric value on the y scale

**Value**

A single numeric value on the x scale.

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

`sortedXyData, NLSstLfAsymptote, NLSstRtAsymptote, selfStart`

**Examples**

```r
DNase.2 <- DNase[ DNase$Run == "2", ]
DN.srt <- sortedXyData(expression(log(conc)), expression(density), DNase.2)
NLSstClosestX(DN.srt, 1.0)
```

---

**NLSstLfAsymptote**

*Horizontal Asymptote on the Left Side*

**Description**

Provide an initial guess at the horizontal asymptote on the left side (i.e., small values of x) of the graph of y versus x from the xy object. Primarily used within initial functions for self-starting nonlinear regression models.

**Usage**

NLSstLfAsymptote(xy)

**Arguments**

- `xy`: a `sortedXyData` object
NLSstrtAsymptote

Value
A single numeric value estimating the horizontal asymptote for small x.

Author(s)
José Pinheiro and Douglas Bates

See Also
sortedXyData, NLSstClosestX, NLSstrtAsymptote, selfStart

Examples
DNase.2 <- DNase[ DNase$Run == "2", ]
DN.srt <- sortedXyData( expression(log(conc)), expression(density), DNase.2 )
NLSstrtAsymptote( DN.srt )

NLSstrtAsymptote  Horizontal Asymptote on the Right Side

Description
Provide an initial guess at the horizontal asymptote on the right side (i.e., large values of x) of the graph of y versus x from the xy object. Primarily used within initial functions for self-starting nonlinear regression models.

Usage
NLSstrtAsymptote(xy)

Arguments
xy  a sortedXyData object

Value
A single numeric value estimating the horizontal asymptote for large x.

Author(s)
José Pinheiro and Douglas Bates

See Also
sortedXyData, NLSstClosestX, NLSstrtAsymptote, selfStart

Examples
DNase.2 <- DNase[ DNase$Run == "2", ]
DN.srt <- sortedXyData( expression(log(conc)), expression(density), DNase.2 )
NLSstrtAsymptote( DN.srt )
**nobs**

*Extract the Number of Observations from a Fit.*

**Description**

Extract the number of ‘observations’ from a model fit. This is principally intended to be used in computing BIC (see AIC).

**Usage**

```r
nobs(object, ...)  
```  

```r  
## Default S3 method:  
nobs(object, use.fallback = FALSE, ...)  
```  

**Arguments**

- `object` A fitted model object.
- `use.fallback` logical: should fallback methods be used to try to guess the value?
- `...` Further arguments to be passed to methods.

**Details**

This is a generic function, with an S4 generic in package stats4. There are methods in this package for objects of classes "lm", "glm", "nls" and "logLik", as well as a default method (which throws an error, unless `use.fallback = TRUE` when it looks for weights and residuals components – use with care!).

The main usage is in determining the appropriate penalty for BIC, but `nobs` is also used by the stepwise fitting methods `step`, `add1` and `drop1` as a quick check that different fits have been fitted to the same set of data (and not, say, that further rows have been dropped because of NAs in the new predictors).

For `lm`, `glm` and `nls` fits, observations with zero weight are not included.

**Value**

A single number, normally an integer. Could be NA.

**See Also**

AIC.
The Normal Distribution

Description
Density, distribution function, quantile function and random generation for the normal distribution with mean equal to \( \text{mean} \) and standard deviation equal to \( \text{sd} \).

Usage
- \( \text{dnorm}(x, \text{mean} = 0, \text{sd} = 1, \text{log} = \text{FALSE}) \)
- \( \text{pnorm}(q, \text{mean} = 0, \text{sd} = 1, \text{lower.tail} = \text{TRUE}, \text{log.p} = \text{FALSE}) \)
- \( \text{qnorm}(p, \text{mean} = 0, \text{sd} = 1, \text{lower.tail} = \text{TRUE}, \text{log.p} = \text{FALSE}) \)
- \( \text{rnorm}(n, \text{mean} = 0, \text{sd} = 1) \)

Arguments
- \( x, q \) vector of quantiles.
- \( p \) vector of probabilities.
- \( n \) number of observations. If \( \text{length}(n) > 1 \), the length is taken to be the number required.
- \( \text{mean} \) vector of means.
- \( \text{sd} \) vector of standard deviations.
- \( \text{log}, \text{log.p} \) logical; if TRUE, probabilities \( p \) are given as \( \log(p) \).
- \( \text{lower.tail} \) logical; if TRUE (default), probabilities are \( P[X \leq x] \) otherwise, \( P[X > x] \).

Details
If \( \text{mean} \) or \( \text{sd} \) are not specified they assume the default values of 0 and 1, respectively.

The normal distribution has density
\[
f(x) = \frac{1}{\sqrt{2\pi\sigma}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}
\]
where \( \mu \) is the mean of the distribution and \( \sigma \) the standard deviation.

Value
- \( \text{dnorm} \) gives the density, \( \text{pnorm} \) gives the distribution function, \( \text{qnorm} \) gives the quantile function, and \( \text{rnorm} \) generates random deviates.

The length of the result is determined by \( n \) for \( \text{rnorm} \), and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

For \( \text{sd} = 0 \) this gives the limit as \( \text{sd} \) decreases to 0, a point mass at \( \mu \). \( \text{sd} < 0 \) is an error and returns NaN.
Source

For \texttt{pnorm}, based on

For \texttt{qnorm}, the code is a C translation of

which provides precise results up to about 16 digits.

For \texttt{rnorm}, see \texttt{RNG} for how to select the algorithm and for references to the supplied methods.

Examples

```r
require(graphics)

dnorm(0) == 1/sqrt(2*pi)
dnorm(1) == exp(-1/2)/sqrt(2*pi)
dnorm(1) == 1/sqrt(2*pi*exp(1))

## Using "log = TRUE" for an extended range :
par(mfrow = c(2,1))
plot(function(x) dnorm(x, log = TRUE), -60, 50, 
main = "log (Normal density)")
curve(log(dnorm(x)), add = TRUE, col = "red", lwd = 2)
mtext("log(dnorm(x))", col = "red", adj = 1)

plot(function(x) pnorm(x, log.p = TRUE), -50, 10, 
main = "log (Normal Cumulative)")
curve(log(pnorm(x)), add = TRUE, col = "red", lwd = 2)
mtext("log(pnorm(x))", col = "red", adj = 1)

## if you want the so-called 'error function'
qnorm <- function(x) 2 * pnorm(x * sqrt(2)) - 1

## (see Abramowitz and Stegun 29.2.29)
## and the so-called 'complementary error function'
erfc <- function(x) 2 * pnorm(x * sqrt(2), lower = FALSE)

## and the inverses
qnorm((1 + x)/2)/sqrt(2)
erfcinv <- function(x) qnorm(x/2, lower = FALSE)/sqrt(2)
```
numericDeriv Evaluate Derivatives Numerically

Description

numericDeriv numerically evaluates the gradient of an expression.

Usage

numericDeriv(expr, theta, rho = parent.frame(), dir = 1.0)

Arguments

expr The expression to be differentiated. The value of this expression should be a numeric vector.
theta A character vector of names of numeric variables used in expr.
rho An environment containing all the variables needed to evaluate expr.
dir A numeric vector of directions to use for the finite differences.

Details

This is a front end to the C function numeric_deriv, which is described in Writing R Extensions.

The numeric variables must be of type real and not integer.

Value

The value of eval(expr, envir = rho) plus a matrix attribute called gradient. The columns of this matrix are the derivatives of the value with respect to the variables listed in theta.

Author(s)

Saikat DebRoy <saikat@stat.wisc.edu>

Examples

myenv <- new.env()
assign("mean", 0., envir = myenv)
assign("sd", 1., envir = myenv)
assign("x", seq(-3., 3., len = 3)), envir = myenv)
numericDeriv(quote(pnorm(x, mean, sd)), c("mean", "sd"), myenv)
Offset

Description
An offset is a term to be added to a linear predictor, such as in a generalised linear model, with known coefficient 1 rather than an estimated coefficient.

Usage
offset(object)

Arguments
object An offset to be included in a model frame

Details
There can be more than one offset in a model formula, but - is not supported for offset terms (and is equivalent to +).

Value
The input value.

See Also
model.offset, model.frame.
For examples see glm and Insurance in package MASS.

One-way Test

Description
Test whether two or more samples from normal distributions have the same means. The variances are not necessarily assumed to be equal.

Usage
oneway.test(formula, data, subset, na.action, var.equal = FALSE)
Arguments

formula a formula of the form lhs ~ rhs where lhs gives the sample values and rhs the corresponding groups.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
var.equal a logical variable indicating whether to treat the variances in the samples as equal. If TRUE, then a simple F test for the equality of means in a one-way analysis of variance is performed. If FALSE, an approximate method of Welch (1951) is used, which generalizes the commonly known 2-sample Welch test to the case of arbitrarily many samples.

Details

If the right-hand side of the formula contains more than one term, their interaction is taken to form the grouping.

Value

A list with class "htest" containing the following components:

statistic the value of the test statistic.
parameter the degrees of freedom of the exact or approximate F distribution of the test statistic.
p.value the p-value of the test.
method a character string indicating the test performed.
data.name a character string giving the names of the data.

References

See Also

The standard t test (t.test) as the special case for two samples; the Kruskal-Wallis test kruskal.test for a nonparametric test for equal location parameters in a one-way layout.

Examples

## Not assuming equal variances
oneway.test(extra ~ group, data = sleep)
## Assuming equal variances
oneway.test(extra ~ group, data = sleep, var.equal = TRUE)
## which gives the same result as
anova(lm(extra ~ group, data = sleep))
optim

General-purpose Optimization

Description

General-purpose optimization based on Nelder-Mead, quasi-Newton and conjugate-gradient algorithms. It includes an option for box-constrained optimization and simulated annealing.

Usage

```r
optim(par, fn, gr = NULL, ...,
      method = c("Nelder-Mead", "BFGS", "CG", "L-BFGS-B", "SANN",
                 "Brent"),
      lower = -Inf, upper = Inf,
      control = list(), hessian = FALSE)

optimHess(par, fn, gr = NULL, ..., control = list())
```

Arguments

- `par` Initial values for the parameters to be optimized over.
- `fn` A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.
- `gr` A function to return the gradient for the "BFGS", "CG" and "L-BFGS-B" methods. If it is `null`, a finite-difference approximation will be used. For the "SANN" method it specifies a function to generate a new candidate point. If it is `null` a default Gaussian Markov kernel is used.
- `...` Further arguments to be passed to `fn` and `gr`.
- `method` The method to be used. See ‘Details’.
- `lower`, `upper` Bounds on the variables for the "L-BFGS-B" method, or bounds in which to search for method "Brent".
- `control` A list of control parameters. See ‘Details’.
- `hessian` Logical. Should a numerically differentiated Hessian matrix be returned?

Details

Note that arguments after `...` must be matched exactly.

By default `optim` performs minimization, but it will maximize if `control$fnscale` is negative. `optimHess` is an auxiliary function to compute the Hessian at a later stage if `hessian = TRUE` was forgotten.

The default method is an implementation of that of Nelder and Mead (1965), that uses only function values and is robust but relatively slow. It will work reasonably well for non-differentiable functions.

Method "BFGS" is a quasi-Newton method (also known as a variable metric algorithm), specifically that published simultaneously in 1970 by Broyden, Fletcher, Goldfarb and Shanno. This uses function values and gradients to build up a picture of the surface to be optimized.
Method "CG" is a conjugate gradients method based on that by Fletcher and Reeves (1964) (but with the option of Polak–Ribiere or Beale–Sorenson updates). Conjugate gradient methods will generally be more fragile than the BFGS method, but as they do not store a matrix they may be successful in much larger optimization problems.

Method "L-BFGS-B" is that of Byrd et. al. (1995) which allows box constraints, that is each variable can be given a lower and/or upper bound. The initial value must satisfy the constraints. This uses a limited-memory modification of the BFGS quasi-Newton method. If non-trivial bounds are supplied, this method will be selected, with a warning.

Nocedal and Wright (1999) is a comprehensive reference for the previous three methods.

Method "SANN" is by default a variant of simulated annealing given in Belisle (1992). Simulated-annealing belongs to the class of stochastic global optimization methods. It uses only function values but is relatively slow. It will also work for non-differentiable functions. This implementation uses the Metropolis function for the acceptance probability. By default the next candidate point is generated from a Gaussian Markov kernel with scale proportional to the actual temperature. If a function to generate a new candidate point is given, method "SANN" can also be used to solve combinatorial optimization problems. Temperatures are decreased according to the logarithmic cooling schedule as given in Belisle (1992, p. 890); specifically, the temperature is set to $\frac{t}{\log((t-1) \% \% \ tmax + \ exp(1)))}$, where $t$ is the current iteration step and $t$ and $tmax$ are specifiable via control, see below. Note that the "SANN" method depends critically on the settings of the control parameters. It is not a general-purpose method but can be very useful in getting to a good value on a very rough surface.

Method "Brent" is for one-dimensional problems only, using optimize(). It can be useful in cases where optim() is used inside other functions where only method can be specified, such as in mle from package stats4.

Function fn can return NA or Inf if the function cannot be evaluated at the supplied value, but the initial value must have a computable finite value of fn. (Except for method "L-BFGS-B" where the values should always be finite.)

optim can be used recursively, and for a single parameter as well as many. It also accepts a zero-length par, and just evaluates the function with that argument.

The control argument is a list that can supply any of the following components:

- trace Non-negative integer. If positive, tracing information on the progress of the optimization is produced. Higher values may produce more tracing information: for method "L-BFGS-B" there are six levels of tracing. (To understand exactly what these do see the source code: higher levels give more detail.)

- fnscale An overall scaling to be applied to the value of fn and gr during optimization. If negative, turns the problem into a maximization problem. Optimization is performed on fn(par)/fnscale.

- parscale A vector of scaling values for the parameters. Optimization is performed on par/parscale and these should be comparable in the sense that a unit change in any element produces about a unit change in the scaled value. Not used (nor needed) for method = "Brent".

- ndeps A vector of step sizes for the finite-difference approximation to the gradient, on par/parscale scale. Defaults to 1e-3.

- maxit The maximum number of iterations. Defaults to 100 for the derivative-based methods, and 500 for "Nelder–Mead".
  For "SANN" maxit gives the total number of function evaluations: there is no other stopping criterion. Defaults to 10000.

- abstol The absolute convergence tolerance. Only useful for non-negative functions, as a tolerance for reaching zero.
reltol Relative convergence tolerance. The algorithm stops if it is unable to reduce the
value by a factor of\( \text{reltol} \times (\text{abs(val)} + \text{reltol}) \) at a step. Defaults to
\( \text{sqrt(Machine}\_\text{double}\_\text{eps}) \), typically about 1e-8.
alpha, beta, gamma Scaling parameters for the "Nelder-Mead" method. alpha is the reflection
factor (default 1.0), beta the contraction factor (0.5) and gamma the expansion factor (2.0).
REPORT The frequency of reports for the "BFGS", "L-BFGS-B" and "SANN" methods if
control$trace is positive. Defaults to every 10 iterations for "BFGS" and "L-BFGS-B", or
every 100 temperatures for "SANN".
type for the conjugate-gradients method. Takes value 1 for the Fletcher-Reeves update, 2 for
Polak–Ribiere and 3 for Beale–Sorenson.
lmm is an integer giving the number of BFGS updates retained in the "L-BFGS-B" method. It de-
defaults to 5.
factr controls the convergence of the "L-BFGS-B" method. Convergence occurs when the reduc-
tion in the objective is within this factor of the machine tolerance. Default is 1e7, that is a
tolerance of about 1e-8.
pgtol helps control the convergence of the "L-BFGS-B" method. It is a tolerance on the projected
gradient in the current search direction. This defaults to zero, when the check is suppressed.
temp controls the "SANN" method. It is the starting temperature for the cooling schedule. Defaults
to 10.
tmax is the number of function evaluations at each temperature for the "SANN" method. Defaults
to 10.

Any names given to par will be copied to the vectors passed to fn and gr. Note that no other
attributes of par are copied over.
The parameter vector passed to fn has special semantics and may be shared between calls: the
function should not change or copy it.

Value

For optim, a list with components:

- par The best set of parameters found.
- value The value of fn corresponding to par.
- counts A two-element integer vector giving the number of calls to fn and gr respectively.
  This excludes those calls needed to compute the Hessian, if requested,
  and any calls to fn to compute a finite-difference approximation to the gradient.
- convergence An integer code. 0 indicates successful completion (which is always the case for
  "SANN" and "Brent"). Possible error codes are
  1 indicates that the iteration limit maxit had been reached.
  10 indicates degeneracy of the Nelder–Mead simplex.
  51 indicates a warning from the "L-BFGS-B" method; see component message
  for further details.
  52 indicates an error from the "L-BFGS-B" method; see component message
  for further details.
- message A character string giving any additional information returned by the optimizer,
or NULL.
- hessian Only if argument hessian is true. A symmetric matrix giving an estimate of the
  Hessian at the solution found. Note that this is the Hessian of the unconstrained
  problem even if the box constraints are active.

For optimHess, the description of the hessian component applies.
Note

optim will work with one-dimensional pars, but the default method does not work well (and will warn). Method "Brent" uses optimize and needs bounds to be available; "BFGS" often works well enough if not.

Source

The code for methods "Nelder-Mead", "BFGS" and "CG" was based originally on Pascal code in Nash (1990) that was translated by p2c and then hand-optimized. Dr Nash has agreed that the code can be made freely available.

The code for method "L-BFGS-B" is based on Fortran code by Zhu, Byrd, Lu-Chen and Nocedal obtained from Netlib (file `opt/lbfgs_bcm.shar`; another version is in `toms/778`).

The code for method "SANN" was contributed by A. Trapletti.

     angle = 10, col = "green")
text(x, y, labels(eurodist), cex = 0.8)

set.seed(123) # chosen to get a good soln relatively quickly
The function `optimize` searches the interval from `lower` to `upper` for a minimum or maximum of the function `f` with respect to its first argument.

`optimise` is an alias for `optimize`.

**Usage**

```r
optimize(f = , interval = , ..., lower = min(interval),
          upper = max(interval), maximum = FALSE,
          tol = .Machine$double.eps^0.25)
optimise(f = , interval = , ..., lower = min(interval),
          upper = max(interval), maximum = FALSE,
          tol = .Machine$double.eps^0.25)
```

**Arguments**

- `f` the function to be optimized. The function is either minimized or maximized over its first argument depending on the value of `maximum`.
- `interval` a vector containing the end-points of the interval to be searched for the minimum.
- `...` additional named or unnamed arguments to be passed to `f`.
- `lower` the lower end point of the interval to be searched.
- `upper` the upper end point of the interval to be searched.
- `maximum` logical. Should we maximize or minimize (the default)?
- `tol` the desired accuracy.

**Details**

Note that arguments after `...` must be matched exactly.

The method used is a combination of golden section search and successive parabolic interpolation, and was designed for use with continuous functions. Convergence is never much slower than that for a Fibonacci search. If `f` has a continuous second derivative which is positive at the minimum (which is not at `lower` or `upper`), then convergence is superlinear, and usually of the order of about 1.324.
The function \( f \) is never evaluated at two points closer together than \( \epsilon |x_0| + (tol/3) \), where \( \epsilon \) is approximately \( \sqrt{\text{Machine}\$\text{double}\.eps} \) and \( x_0 \) is the final abscissa of \( f \). If \( f \) is a unimodal function and the computed values of \( f \) are always unimodal when separated by at least \( \epsilon |x| + (tol/3) \), then \( x_0 \) approximates the abscissa of the global minimum of \( f \) on the interval \( \text{lower}, \text{upper} \) with an error less than \( \epsilon |x_0| + tol \).

If \( f \) is not unimodal, then \( \text{optimize}() \) may approximate a local, but perhaps non-global, minimum to the same accuracy.

The first evaluation of \( f \) is always at \( x_1 = a + (1 - \phi)(b - a) \) where \( (a, b) = (\text{lower}, \text{upper}) \) and \( \phi = (\sqrt{5} - 1)/2 = 0.61803\ldots \) is the golden section ratio. Almost always, the second evaluation is at \( x_2 = a + \phi(b - a) \). Note that a local minimum inside \( [x_1, x_2] \) will be found as solution, even when \( f \) is constant in there, see the last example.

\( f \) will be called as \( f(x, \ldots) \) for a numeric value of \( x \).

The argument passed to \( f \) has special semantics and used to be shared between calls. The function should not copy it.

**Value**

A list with components \texttt{minimum} (or \texttt{maximum}) and \texttt{objective} which give the location of the minimum (or maximum) and the value of the function at that point.

**Source**

A C translation of Fortran code \url{http://www.netlib.org/fmm/fmin.f} (author(s) unstated) based on the Algol 60 procedure \texttt{localmin} given in the reference.

**References**

**See Also**

**Examples**

```r
require(graphics)

f <- function(x, a) (x - a)^2
xmin <- optimize(f, c(0, 1), tol = 0.0001, a = 1/3)
xmin

## See where the function is evaluated:
optimize(function(x) x^2*(print(x)-1), lower = 0, upper = 10)

## "wrong" solution with unlucky interval and piecewise constant \( f() \):
f <- function(x) ifelse(x > -1, ifelse(x < 4, exp(-1/abs(x - 1)), 10), 10)
fp <- function(x) { print(x); f(x) }
plot(f, -2.5, ylim = 0:1, col = 2)
optimize(fp, c(-4, 20))  # doesn't see the minimum
optimize(fp, c(-7, 20))  # ok
```
order.dendrogram  

Ordering or Labels of the Leaves in a Dendrogram

Description

These functions return the order (index) or the "label" attribute for the leaves in a dendrogram. These indices can then be used to access the appropriate components of any additional data.

Usage

order.dendrogram(x)

## S3 method for class 'dendrogram'
lables(object, ...)  

Arguments

x, object a dendrogram (see as.dendrogram).
... additional arguments

Details

The indices or labels for the leaves in left to right order are retrieved.

Value

A vector with length equal to the number of leaves in the dendrogram is returned. From r <- order.dendrogram(), each element is the index into the original data (from which the dendrogram was computed).

Author(s)

R. Gentleman (order.dendrogram) and Martin Maechler (labels.dendrogram).

See Also

reorder.dendrogram.

Examples

set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
hc$order
dd <- as.dendrogram(hc)
order.dendrogram(dd) ## the same:
stopifnot(hc$order == order.dendrogram(dd))

d2 <- as.dendrogram(hclust(dist(USArrests)))
lables(d2) ## in this case the same as
stopifnot(identical(lables(d2), rownames(USArrests)[order.dendrogram(d2)]))
p.adjust

Adjust P-values for Multiple Comparisons

Description

Given a set of p-values, returns p-values adjusted using one of several methods.

Usage

p.adjust(p, method = p.adjust.methods, n = length(p))

p.adjust.methods

# c("holm", "hochberg", "hommel", "bonferroni", "BH", "BY",
#    "fdr", "none")

Arguments

p numeric vector of p-values (possibly with NAs). Any other R is coerced by as.numeric.
method correction method
n number of comparisons, must be at least length(p); only set this (to non-default) when you know what you are doing!

Details

The adjustment methods include the Bonferroni correction ("bonferroni") in which the p-values are multiplied by the number of comparisons. Less conservative corrections are also included by Holm (1979) ("holm"), Hochberg (1988) ("hochberg"), Hommel (1988) ("hommel"), Benjamini & Hochberg (1995) ("BH" or its alias "fdr"), and Benjamini & Yekutieli (2001) ("BY"), respectively. A pass-through option ("none") is also included. The set of methods are contained in the p.adjust.methods vector for the benefit of methods that need to have the method as an option and pass it on to p.adjust.

The first four methods are designed to give strong control of the family-wise error rate. There seems no reason to use the unmodified Bonferroni correction because it is dominated by Holm’s method, which is also valid under arbitrary assumptions.

Hochberg’s and Hommel’s methods are valid when the hypothesis tests are independent or when they are non-negatively associated (Sarkar, 1998; Sarkar and Chang, 1997). Hommel’s method is more powerful than Hochberg’s, but the difference is usually small and the Hochberg p-values are faster to compute.

The "BH" (aka "fdr") and "BY" method of Benjamini, Hochberg, and Yekutieli control the false discovery rate, the expected proportion of false discoveries amongst the rejected hypotheses. The false discovery rate is a less stringent condition than the family-wise error rate, so these methods are more powerful than the others.

Note that you can set n larger than length(p) which means the unobserved p-values are assumed to be greater than all the observed p for "bonferroni" and "holm" methods and equal to 1 for the other methods.

Value

A numeric vector of corrected p-values (of the same length as p, with names copied from p).
References

pairwise.* functions such as pairwise.t.test.

Examples

```
require(graphics)

set.seed(123)
x <- rnorm(50, mean = c(rep(0, 25), rep(3, 25)))
p <- 2*pnorm(sort(-abs(x)))

round(p, 3)
round(p.adjust(p), 3)
round(p.adjust(p, "BH"), 3)

## or all of them at once (dropping the "fdr" alias):
p.adj <- sapply(p.adjust.M, function(meth) p.adjust(p, meth))
p.adj.60 <- sapply(p.adjust.M, function(meth) p.adjust(p, meth, n = 60))
stopifnot(identical(p.adj[,"none"], p), p.adj <= p.adj.60)
round(p.adj, 3)
## or a bit nicer:
noquote(apply(p.adj, 2, format.pval, digits = 3))

## and a graphic:
matplot(p, p.adj, ylab="p.adjust(p, meth)", type="l", xaxs = "i", asp = 1, lty = 1:6,
main = "P-value adjustments")
legend(0.7, 0.6, p.adjust.M, col = 1:6, lty = 1:6)

## Can work with NA's:
```
pairwise.prop.test

Pairwise comparisons for proportions

Description

Calculate pairwise comparisons between pairs of proportions with correction for multiple testing

Usage

cpairwise.prop.test(x, n, p.adjust.method = p.adjust.methods, ...)

Arguments

x Vector of counts of successes or a matrix with 2 columns giving the counts of successes and failures, respectively.
n Vector of counts of trials; ignored if x is a matrix.
p.adjust.method Method for adjusting p values (see p.adjust)
... Additional arguments to pass to prop.test

Value

Object of class "pairwise.htest"

See Also

prop.test, p.adjust

Examples

smokers <- c(83, 90, 129, 70)
patients <- c(86, 93, 136, 82)
pairwise.prop.test(smokers, patients)
pairwise.t.test  

Pairwise t tests

Description

Calculate pairwise comparisons between group levels with corrections for multiple testing

Usage

```r
pairwise.t.test(x, g, p.adjust.method = p.adjust.methods,
    pool.sd = !paired, paired = FALSE,
    alternative = c("two.sided", "less", "greater"),
    ...)
```

Arguments

- `x`: response vector.
- `g`: grouping vector or factor.
- `pool.sd`: switch to allow/disallow the use of a pooled SD
- `paired`: a logical indicating whether you want paired t-tests.
- `alternative`: a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less".
- `...`: additional arguments to pass to `t.test`.

Details

The `pool.sd` switch calculates a common SD for all groups and uses that for all comparisons (this can be useful if some groups are small). This method does not actually call `t.test`, so extra arguments are ignored. Pooling does not generalize to paired tests so `pool.sd` and `paired` cannot both be TRUE.

Only the lower triangle of the matrix of possible comparisons is being calculated, so setting `alternative` to anything other than "two.sided" requires that the levels of `g` are ordered sensibly.

Value

Object of class "pairwise.htest"

See Also

`t.test`, `p.adjust`

Examples

```r
attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
pairwise.t.test(Ozone, Month)
pairwise.t.test(Ozone, Month, p.adj = "bonf")
pairwise.t.test(Ozone, Month, pool.sd = FALSE)
detach()
```
pairwise.table  

Tabulate p values for pairwise comparisons

Description

Creates table of p values for pairwise comparisons with corrections for multiple testing.

Usage

pairwise.table(compare.levels, level.names, p.adjust.method)

Arguments

compare.levels Function to compute (raw) p value given indices i and j
level.names Names of the group levels
p.adjust.method Method for multiple testing adjustment

Details

Functions that do multiple group comparisons create separate compare.levels functions (assumed to be symmetrical in i and j) and passes them to this function.

Value

Table of p values in lower triangular form.

See Also

pairwise.t.test

pairwise.wilcox.test  

Pairwise Wilcoxon Rank Sum Tests

Description

Calculate pairwise comparisons between group levels with corrections for multiple testing.

Usage

pairwise.wilcox.test(x, g, p.adjust.method = p.adjust.methods, paired = FALSE, ...)

Arguments

x response vector.

g grouping vector or factor.
p.adjust.method method for adjusting p values (see p.adjust).
paired a logical indicating whether you want a paired test.
... additional arguments to pass to wilcoxon.test.
Details

Extra arguments that are passed on to wilcox.test may or may not be sensible in this context. In particular, only the lower triangle of the matrix of possible comparisons is being calculated, so setting alternative to anything other than "two.sided" requires that the levels of g are ordered sensibly.

Value

Object of class "pairwise.htest"

See Also

wilcox.test, p.adjust

Examples

attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
## These give warnings because of ties :
pairwise.wilcox.test(Ozone, Month)
pairwise.wilcox.test(Ozone, Month, p.adj = "bonf")
detach()

plot.acf

Plot Autocovariance and Autocorrelation Functions

Description

Plot method for objects of class "acf".

Usage

## S3 method for class 'acf'
plot(x, ci = 0.95, type = "h", xlab = "Lag", ylab = NULL, ylim = NULL, main = NULL, ci.col = "blue", ci.type = c("white", "ma"), max.mfrow = 6, ask = Npgs > 1 && dev.interactive(), mar = if (nser > 2) c(3,2,2,0.8) else par("mar"), oma = if (nser > 2) c(1,1.2,1,1) else par("oma"), mgp = if (nser > 2) c(1.5,0.6,0.6) else par("mgp"), xpd = par("xpd"), cex.main = if (nser > 2) 1 else par("cex.main"), verbose = getOption("verbose"), ...

Arguments

x an object of class "acf".

.ci coverage probability for confidence interval. Plotting of the confidence interval is suppressed if ci is zero or negative.

type the type of plot to be drawn, default to histogram like vertical lines.
xlab  the x label of the plot.
ylab  the y label of the plot.
ylim numeric of length 2 giving the y limits for the plot.
main overall title for the plot.
ci.col colour to plot the confidence interval lines.
ci.type should the confidence limits assume a white noise input or for lag \( k \) an MA\((k-1)\) input?
max.mfrow positive integer; for multivariate \( x \) indicating how many rows and columns of plots should be put on one page, using \( \text{par}(\text{mfrow} = c(m,m)) \).
ask logical; if TRUE, the user is asked before a new page is started.
mar, oma, mgp, xpd, cex.main graphics parameters as in \( \text{par}(\cdot) \), by default adjusted to use smaller than default margins for multivariate \( x \) only.
verbose logical. Should \( R \) report extra information on progress?
... graphics parameters to be passed to the plotting routines.

Note
The confidence interval plotted in \( \text{plot.acf} \) is based on an uncorrelated series and should be treated with appropriate caution. Using \( \text{ci.type} = "ma" \) may be less potentially misleading.

See Also
\( \text{acf} \) which calls \( \text{plot.acf} \) by default.

Examples
\begin{verbatim}
require(graphics)

z4 <- ts(matrix(rnorm(400), 100, 4), start = c(1961, 1), frequency = 12)
z7 <- ts(matrix(rnorm(700), 100, 7), start = c(1961, 1), frequency = 12)
acf(z4)
acf(z7, max.mfrow = 7)  # squeeze onto 1 page
acf(z7)  # multi-page
\end{verbatim
Arguments

\( x \)

a "density" object.

\( \text{main, xlab, ylab, type} \)

plotting parameters with useful defaults.

\( \ldots \)

further plotting parameters.

\( \text{zero.line} \)

logical; if TRUE, add a base line at \( y = 0 \)

Value

None.

See Also

density.

---

plot.HoltWinters

Plot function for \texttt{HoltWinters} objects

Description

Produces a chart of the original time series along with the fitted values. Optionally, predicted values (and their confidence bounds) can also be plotted.

Usage

\[
\text{## S3 method for class 'HoltWinters'} \\
\text{plot}(x, \text{predicted.values} = \text{NA}, \text{intervals} = \text{TRUE}, \text{separat} = \text{TRUE}, \text{col} = 1, \text{col.predicted} = 2, \text{col.intervals} = 4, \text{col.separator} = 1, \text{lty} = 1, \text{lty.predicted} = 1, \text{lty.intervals} = 1, \text{lty.separator} = 3, \text{ylab} = \text{"Observed / Fitted"}, \text{main} = \text{"Holt-Winters filtering"}, \text{ylim} = \text{NULL}, \ldots)
\]

Arguments

\( x \)

Object of class \texttt{"HoltWinters"}

\( \text{predicted.values} \)

Predicted values as returned by \texttt{predict.HoltWinters}

\( \text{intervals} \)

If TRUE, the prediction intervals are plotted (default).

\( \text{separat} \)

If TRUE, a separating line between fitted and predicted values is plotted (default).

\( \text{col}, \text{lty} \)

Color/line type of original data (default: black solid).

\( \text{col.predicted, lty.predicted} \)

Color/line type of fitted and predicted values (default: red solid).

\( \text{col.intervals, lty.intervals} \)

Color/line type of prediction intervals (default: blue solid).

\( \text{col.separator, lty.separator} \)

Color/line type of observed/predicted values separator (default: black dashed).
plot.isoreg

- **ylab**: Label of the y-axis.
- **main**: Main title.
- **ylim**: Limits of the y-axis. If NULL, the range is chosen such that the plot contains the original series, the fitted values, and the predicted values if any.
- **...**: Other graphics parameters.

**Author(s)**

David Meyer <David.Meyer@wu.ac.at>

**References**

---

**plot.isoreg**

*Plot Method for isoreg Objects*

**Description**

The `plot` and `lines` method for R objects of class `isoreg`.

**Usage**

```r
## S3 method for class 'isoreg'
plot(x, plot.type = c("single", "row.wise", "col.wise"),
     main = paste("Isotonic regression", deparse(x$call)),
     xlab = "x0", ylab = "x$y",
     par.fit = list(col = "red", cex = 1.5, pch = 13, lwd = 1.5),
     mar = if (both) 0.1 + c(3.5, 2.5, 1, 1) else par("mar"),
     mgp = if (both) c(1.6, 0.7, 0) else par("mgp"),
     grid = length(x$x) < 12, ...)

## S3 method for class 'isoreg'
lines(x, col = "red", lwd = 1.5,
       do.points = FALSE, cex = 1.5, pch = 13, ...)
```
Arguments

- `x`: an `isoreg` object.
- `plot.type`: character indicating which type of plot is desired. The first (default) only draws the data and the fit, where the others add a plot of the cumulative data and fit.
- `main`: main title of plot, see `title`.
- `main2`: title for second (cumulative) plot.
- `xlab`, `ylab`: x- and y- axis annotation.
- `par.fit`: a list of arguments (for `points` and `lines`) for drawing the fit.
- `mar`, `mgp`: graphical parameters, see `par`, mainly for the case of two plots.
- `grid`: logical indicating if grid lines should be drawn. If true, `grid()` is used for the first plot, where as vertical lines are drawn at ‘touching’ points for the cumulative plot.
- `do.points`: for `lines()`: logical indicating if the step points should be drawn as well (and as they are drawn in `plot()`).
- `col`, `lwd`, `cex`, `pch`: graphical arguments for `lines()`, where `cex` and `pch` are only used when `do.points` is TRUE.
- `...`: further arguments passed to and from methods.

See Also

`isoreg` for computation of `isoreg` objects.

Examples

```r
require(graphics)

utils::example(isoreg) # for the examples there

plot(y3, main = "simple plot(.) + lines(isoreg())")
lines(ir3)

## 'same' plot as above, "proving" that only ranks of 'x' are important
plot(isoreg(2^c(1:9), c(1,0,4,3,3,5,4,2,0)), plot.type = "row", log = "x")

plot(ir3, plot.type = "row", ylab = "y3")
plot(isoreg(y3 - 4), plot.type="r", ylab = "y3 - 4")
plot(ir4, plot.type = "ro", ylab = "y4", xlab = "x = 1:n")

## experiment a bit with these (C=c C-j):
plot(isoreg(sample(9), y3), plot.type = "row")
plot(isoreg(sample(9), y3), plot.type = "col.wise")

plot(ir <- isoreg(sample(10), sample(10), replace = TRUE)),
    plot.type = "r")
```
plot.lm

Plot Diagnostics for an lm Object

Description

Six plots (selectable by which) are currently available: a plot of residuals against fitted values, a
Scale-Location plot of $\sqrt{|\text{residuals}|}$ against fitted values, a Normal Q-Q plot, a plot of Cook’s
distances versus row labels, a plot of residuals against leverages, and a plot of Cook’s distances
against leverage/(1-leverage). By default, the first three and 5 are provided.

Usage

```r
## S3 method for class 'lm'
plot(x, which = c(1:3, 5),
caption = list("Residuals vs Fitted", "Normal Q-Q",
  "Scale-Location", "Cook's distance",
  "Residuals vs Leverage",
  expression("Cook's dist vs Leverage " * h[iii] / (1 - h[iii]))),
panel = if(add.smooth) panel.smooth else points,
sub.caption = NULL, main = ";",
ask = prod(par("mfcol")) < length(which) & dev.interactive(),
...

id.n = 3, labels.id = names(residuals(x)), cex.id = 0.75,
qqline = TRUE, cook.levels = c(0.5, 1.0),
add.smooth =getOption("add.smooth"), label.pos = c(4,2),
cex.caption = 1)
```

Arguments

- `x` lm object, typically result of lm or glm.
- `which` if a subset of the plots is required, specify a subset of the numbers 1:6.
- `caption` captions to appear above the plots; character vector or list of valid graphics
  annotations, see as.graphicsAnnot. Can be set to "" or NA to suppress all
  captions.
- `panel` panel function. The useful alternative to points, panel.smooth can be chosen
  by add.smooth = TRUE.
- `sub.caption` common title—above the figures if there are more than one; used as sub
  (s.title) otherwise. If NULL, as by default, a possible abbreviated version of
deparse(x$call) is used.
- `main` title to each plot—in addition to caption.
- `ask` logical; if TRUE, the user is asked before each plot, see par(ask=.).
- `...` other parameters to be passed through to plotting functions.
- `id.n` number of points to be labelled in each plot, starting with the most extreme.
- `labels.id` vector of labels, from which the labels for extreme points will be chosen. NULL
  uses observation numbers.
- `cex.id` magnification of point labels.
- `qqline` logical indicating if a qqline() should be added to the normal Q-Q plot.
plot.lm

cook.levels levels of Cook’s distance at which to draw contours.
add.smooth logical indicating if a smoother should be added to most plots; see also panel above.
label.pos positioning of labels, for the left half and right half of the graph respectively, for plots 1-3.
cex.caption controls the size of caption.

Details

sub.caption—by default the function call—is shown as a subtitle (under the x-axis title) on each plot when plots are on separate pages, or as a subtitle in the outer margin (if any) when there are multiple plots per page.

The ‘Scale-Location’ plot, also called ‘Spread-Location’ or ‘S-L’ plot, takes the square root of the absolute residuals in order to diminish skewness (\(\sqrt{|E|}\)) is much less skewed than \(|E|\) for Gaussian zero-mean \(E\).

The ‘S-L’, the Q-Q, and the Residual-Leverage plot, use standardized residuals which have identical variance (under the hypothesis). They are given as \(R_i/(s \times \sqrt{1-h_{ii}})\) where \(h_{ii}\) are the diagonal entries of the hat matrix, \texttt{influence()}\$hat (see also \texttt{hat}), and where the Residual-Leverage plot uses standardized Pearson residuals (\texttt{residuals.glm(type = ”pearson”)} for \(R[i]\).

The Residual-Leverage plot shows contours of equal Cook’s distance, for values of \texttt{cook.levels} (by default 0.5 and 1) and omits cases with leverage one with a warning. If the leverages are constant (as is typically the case in a balanced \texttt{aov} situation) the plot uses factor level combinations instead of the leverages for the x-axis. (The factor levels are ordered by mean fitted value.)

In the Cook’s distance vs leverage/(1-leverage) plot, contours of standardized residuals that are equal in magnitude are lines through the origin. The contour lines are labelled with the magnitudes.

Examples

```r
require(graphics)

## Analysis of the life-cycle savings data
## given in Belsley, Kuh and Welsch.
lm.SR <- lm(sr ~ pop15 + pop75 + dpi + ddpi, data = LifeCycleSavings)
plot(lm.SR)

## 4 plots on 1 page;
## allow room for printing model formula in outer margin:
par(mfrow = c(2, 2), oma = c(0, 0, 2, 0))
plot(lm.SR)
plot(lm.SR, id.n = NULL)  # no id's
plot(lm.SR, id.n = 5, labels.id = NULL)  # 5 id numbers

## Was default in R <= 2.1.x:
## Cook's distances instead of Residual-Leverage plot
plot(lm.SR, which = 1:4)

## Fit a smooth curve, where applicable:
plot(lm.SR, panel = panel.smooth)
## Gives a smoother curve
plot(lm.SR, panel = function(x, y) panel.smooth(x, y, span = 1))

par(mfrow = c(2, 1))  # same oma as above
plot(lm.SR, which = 1:2, sub.caption = "Saving Rates, n=50, p=5")
```

Description

Plot ridge functions for projection pursuit regression fit.

Usage

```r
## S3 method for class 'ppr'
plot(x, ask, type = "o", ...)  
```

Arguments

- `x`: A fit of class "ppr" as produced by a call to `ppr`
- `ask`: the graphics parameter `ask`: see `par` for details. If set to `TRUE` will ask between the plot of each cross-section.
- `type`: the type of line to draw
- `...`: further graphical parameters

Value

None
Side Effects

A series of plots are drawn on the current graphical device, one for each term in the fit.

See Also

`ppr`, `par`

Examples

```r
require(graphics)

with(rock, {
  areal <- area/10000; peril <- peri/10000
  par(mfrow = c(3,2)) # maybe: , pty = "s"
  rock.ppr <- ppr(log(perm) ~ area + peril + shape,
                 data = rock, nterms = 2, max.terms = 5)
  plot(rock.ppr, main = "ppr(log(perm)^~ , nterms=2, max.terms=5)"

  plot(update(rock.ppr, bass = 5), main = "update(..., bass = 5)"

  plot(update(rock.ppr, sm.method = "gcv", gcvpen = 2),
       main = "update(..., sm.method="gcv", gcvpen=2)"
  })
```

plot.profile.nls  

Plot a profile.nls Object

Description

Displays a series of plots of the profile t function and interpolated confidence intervals for the parameters in a nonlinear regression model that has been fit with `nls` and profiled with `profile.nls`.

Usage

```r
## S3 method for class 'profile.nls'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100,
     absVal = TRUE, ylab = NULL, lty = 2, ...)
```

Arguments

- `x` an object of class "profile.nls"
- `levels` levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually `conf` is used instead of giving `levels` explicitly.
- `conf` a numeric vector of confidence levels for profile-based confidence intervals on the parameters. Defaults to `c(0.99, 0.95, 0.90, 0.80, 0.50)`.
- `absVal` a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to `TRUE`.
- `lty` the line type to be used for axis and dropped lines.
- `ylab`, `...` other arguments to the `plot.default` function can be passed here (but not `xlab`, `xlim`, `ylim` nor `type`).
Details

The plots are produced in a set of hard-coded colours, but as these are coded by number their effect can be changed by setting the `palette`. Colour 1 is used for the axes and 4 for the profile itself. Colours 3 and 6 are used for the axis line at zero and the horizontal/vertical lines dropping to the axes.

**plot.spec**  
*Plotting Spectral Densities*

Description

Plotting method for objects of class "spec". For multivariate time series it plots the marginal spectra of the series or pairs plots of the coherency and phase of the cross-spectra.

Usage

```r
## S3 method for class 'spec'
plot(x, add = FALSE, ci = 0.95, log = c("yes", "dB", "no"),
     xlab = "frequency", ylab = NULL, type = "l",
     ci.col = "blue", ci.lty = 3,
     main = NULL, sub = NULL,
     plot.type = c("marginal", "coherency", "phase"),
```
plot.spec

plot.spec.phase(x, ci = 0.95,
               xlab = "frequency", ylab = "phase",
               ylim = c(-pi, pi), type = "l",
               main = NULL, ci.col = "blue", ci.lty = 3, ...)

plot.spec.coherency(x, ci = 0.95,
                    xlab = "frequency",
                    ylab = "squared coherency",
                    ylim = c(0, 1), type = "l",
                    main = NULL, ci.col = "blue", ci.lty = 3, ...)

Arguments

x an object of class "spec".

add logical. If TRUE, add to already existing plot. Only valid for
plot.type = "marginal".

ci coverage probability for confidence interval. Plotting of the confidence
bar/limits is omitted unless ci is strictly positive.

log If "dB", plot on log10 (decibel) scale (as S-PLUS), otherwise use conventional
log scale or linear scale. Logical values are also accepted. The default is "yes"
unless options(ts.S.compat = TRUE) has been set, when it is "dB". Only
valid for plot.type = "marginal".

xlab the x label of the plot.

ylab the y label of the plot. If missing a suitable label will be constructed.

type the type of plot to be drawn, defaults to lines.

ci.col colour for plotting confidence bar or confidence intervals for coherency and
phase.

ci.lty line type for confidence intervals for coherency and phase.

main overall title for the plot. If missing, a suitable title is constructed.

sub a sub title for the plot. Only used for plot.type = "marginal". If
missing, a description of the smoothing is used.

plot.type For multivariate time series, the type of plot required. Only the first character is
needed.

ylim, ... Graphical parameters.

plot.stepfun

Plot Step Functions

Description

Method of the generic plot for stepfun objects and utility for plotting piecewise constant functions.

Usage

## S3 method for class 'stepfun'
plot(x, xval, xlim, ylim = range(c(y, Fn.kn)),
     xlab = "x", ylab = "f(x)", main = NULL,
     add = FALSE, verticals = TRUE, do.points = (n < 1000),
     pch = par("pch"), col = par("col"),
     col.points = col, cex.points = par("cex"),
     col.hor = col, col.vert = col,
     lty = par("lty"), lwd = par("lwd"), ...)

## S3 method for class 'stepfun'
lines(x, ...)

Arguments

x an R object inheriting from "stepfun".

xval numeric vector of abscissa values at which to evaluate x. Defaults to knots(x) restricted to xlim.

xlim, ylim limits for the plot region: see plot.window. Both have sensible defaults if omitted.

xlab, ylab labels for x and y axis.

main main title.

add logical; if TRUE only add to an existing plot.

verticals logical; if TRUE, draw vertical lines at steps.

do.points logical; if TRUE, also draw points at the (xlim restricted) knot locations. Default is true, for sample size < 1000.

pch character; point character if do.points.

col default color of all points and lines.

col.points character or integer code; color of points if do.points.

cex.points numeric; character expansion factor if do.points.

col.hor color of horizontal lines.

col.vert color of vertical lines.

lty, lwd line type and thickness for all lines.

... further arguments of plot(.), or if(add) segments(.).
Value

A list with two components

- `t`: abscissa (x) values, including the two outermost ones.
- `y`: y values ‘in between’ the `t[]`.

Author(s)

See Also

- `ecdf` for empirical distribution functions as special step functions, `approxfun` and `splinefun`.

Examples

```r
require(graphics)

y0 <- c(1,2,4,3)
sfun0 <- stepfun(1:3, y0, f = 0)
sfun.2 <- stepfun(1:3, y0, f = .2)
sfun1 <- stepfun(1:3, y0, right = TRUE)

tt <- seq(0, 3, by = 0.1)
op <- par(mfrow = c(2,2))
plot(sfun0); plot(sfun0, xval = tt, add = TRUE, col.hor = "bisque")
plot(sfun.2); plot(sfun.2, xval = tt, add = TRUE, col = "orange") # all colors
plot(sfun1); lines(sfun1, xval = tt, col.hor = "coral")

#-- This is revealing :
plot(sfun0, verticals = FALSE,
     main = "stepfun(x, y0, f=f) for f = 0, .2, 1")
for(i in 1:3)
  lines(list(sfun0, sfun.2, stepfun(1:3, y0, f = i)[[i]], col = i)
legend(2.5, 1.9, paste("f =", c(0, 0.2, 1)), col = 1:3, lty = 1, y.intersp = 1)
par(op)

# Extend and/or restrict 'viewport':
plot(sfun0, xlim = c(0,5), ylim = c(0, 3.5),
     main = "plot(stepfun(*), xlim= ., ylim = .)"

#-- this works too (automatic call to ecdf(.)):
plot.stepfun(rt(50, df = 3), col.vert = "gray20")
```

Description

Plotting method for objects inheriting from class "ts".
Usage

## S3 method for class 'ts'
plot(x, y = NULL, plot.type = c("multiple", "single"),
     xy.labels, xy.lines, panel = lines, nc, yax.flip = FALSE,
     mar.multi = c(0, 5.1, 0, if(yax.flip) 5.1 else 2.1),
     oma.multi = c(6, 0, 5, 0), axes = TRUE, ...)

## S3 method for class 'ts'
lines(x, ...)

Arguments

x, y  
time series objects, usually inheriting from class "ts".

plot.type  
for multivariate time series, should the series be plotted separately (with a common time axis) or on a single plot?

xy.labels  
logical, indicating if `text()` labels should be used for an x-y plot, or character, supplying a vector of labels to be used. The default is to label for up to 150 points, and not for more.

xy.lines  
logical, indicating if `lines` should be drawn for an x-y plot. Defaults to the value of `xy.labels` if that is logical, otherwise to `true`.

panel  
a function(x, col, bg, pch, type, ...) which gives the action to be carried out in each panel of the display for `plot.type = "multiple"`. The default is `lines`.

nc  
the number of columns to use when `type = "multiple"`. Defaults to 1 for up to 4 series, otherwise to 2.

yax.flip  
logical indicating if the y-axis (ticks and numbering) should flip from side 2 (left) to 4 (right) from series to series when `type = "multiple"`.

mar.multi, oma.multi  
the (default) `par` settings for `plot.type = "multiple"`. Modify with care!

axes  
logical indicating if x- and y-axes should be drawn.

...  
additional graphical arguments, see `plot, plot.default` and `par`.

Details

If y is missing, this function creates a time series plot, for multivariate series of one of two kinds depending on `plot.type`.

If y is present, both x and y must be univariate, and a scatter plot y ~ x will be drawn, enhanced by using `text` if `xy.labels` is `TRUE` or character, and `lines` if `xy.lines` is `TRUE`.

See Also

`ts` for basic time series construction and access functionality.

Examples

```r
require(graphics)

## Multivariate
z <- ts(matrix(rt(200 * 8, df = 3), 200, 8),
     start = c(1961, 1), frequency = 12)
```
The Poisson Distribution

Description

Density, distribution function, quantile function and random generation for the Poisson distribution with parameter \( \lambda \).

Usage

```r
dpois(x, lambda, log = FALSE)
ppois(q, lambda, lower.tail = TRUE, log.p = FALSE)
qpois(p, lambda, lower.tail = TRUE, log.p = FALSE)
rpois(n, lambda)
```

Arguments

- `x`: vector of (non-negative integer) quantiles.
- `q`: vector of quantiles.
- `p`: vector of probabilities.
- `n`: number of random values to return.
- `lambda`: vector of (non-negative) means.
- `log`, `log.p`: logical; if TRUE, probabilities p are given as \( \log(p) \).
- `lower.tail`: logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).
Details

The Poisson distribution has density

\[ p(x) = \frac{\lambda^x e^{-\lambda}}{x!} \]

for \( x = 0, 1, 2, \ldots \). The mean and variance are \( E(X) = Var(X) = \lambda \).

If an element of \( x \) is not integer, the result of \( \text{dpois} \) is zero, with a warning. \( p(x) \) is computed using Loader’s algorithm, see the reference in \texttt{dbinom}.

The quantile is right continuous: \( \text{qpois}(p, \lambda) \) is the smallest integer \( x \) such that \( P(X \leq x) \geq p \).

Setting \texttt{lower.tail = FALSE} allows to get much more precise results when the default, \texttt{lower.tail = TRUE} would return 1, see the example below.

Value

dpois gives the (log) density, ppois gives the (log) distribution function, qpois gives the quantile function, and rpois generates random deviates.

Invalid \( \lambda \) will result in return value \texttt{NaN}, with a warning.

The length of the result is determined by \( n \) for \( \text{rpois} \), and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Source

dpois uses C code contributed by Catherine Loader (see \texttt{dbinom}).

ppois uses \texttt{pgamma}.

qpois uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

rpois uses

See Also

\texttt{Distributions} for other standard distributions, including \texttt{dbinom} for the binomial and \texttt{dnbinom} for the negative binomial distribution.

\texttt{poisson.test}.

Examples

\begin{verbatim}
require(graphics)

-log(dpois(0:7, lambda = 1)) * gamma(1+ 0:7)) # == 1
Ni <- rpois(50, lambda = 4); table(factor(Ni, 0:max(Ni)))
1 - ppois(10*(15:25), lambda = 100) # becomes 0 (cancellation)
ppois(10*(15:25), lambda = 100, lower.tail = FALSE) # no cancellation
\end{verbatim}
poisson.test

**Description**
Performs an exact test of a simple null hypothesis about the rate parameter in Poisson distribution, or for the ratio between two rate parameters.

**Usage**
```r
poisson.test(x, T = 1, r = 1, 
  alternative = c("two.sided", "less", "greater"), 
  conf.level = 0.95)
```

**Arguments**
- `x` number of events. A vector of length one or two.
- `T` time base for event count. A vector of length one or two.
- `r` hypothesized rate or rate ratio
- `alternative` indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
- `conf.level` confidence level for the returned confidence interval.

**Details**
Confidence intervals are computed similarly to those of `binom.test` in the one-sample case, and using `binom.test` in the two sample case.

**Value**
A list with class "htest" containing the following components:
- `statistic` the number of events (in the first sample if there are two.)
- `parameter` the corresponding expected count
- `p.value` the p-value of the test.
- `conf.int` a confidence interval for the rate or rate ratio.
- `estimate` the estimated rate or rate ratio.
- `null.value` the rate or rate ratio under the null, `r`.
- `alternative` a character string describing the alternative hypothesis.
- `method` the character string "Exact Poisson test" or "Comparison of Poisson rates" as appropriate.
- `data.name` a character string giving the names of the data.
Note

The rate parameter in Poisson data is often given based on a “time on test” or similar quantity (person-years, population size, or expected number of cases from mortality tables). This is the role of the \( t \) argument.

The one-sample case is effectively the binomial test with a very large \( n \). The two sample case is converted to a binomial test by conditioning on the total event count, and the rate ratio is directly related to the odds in that binomial distribution.

See Also

`binom.test`

Examples

```r
### These are paraphrased from data sets in the ISwR package

### SMR, Welsh Nickel workers
poisson.test(137, 24.19893)

### eba1977, compare Fredericia to other three cities for ages 55-59
poisson.test(c(11, 6+8+7), c(800, 1083+1050+878))
```

---

### poly

#### Compute Orthogonal Polynomials

**Description**

Returns or evaluates orthogonal polynomials of degree 1 to degree over the specified set of points \( x \): these are all orthogonal to the constant polynomial of degree 0. Alternatively, evaluate raw polynomials.

**Usage**

```r
poly(x, ..., degree = 1, coefs = NULL, raw = FALSE)
polym(..., degree = 1, raw = FALSE)
```

```r
## S3 method for class 'poly'
predict(object, newdata, ...)
```

**Arguments**

- `x, newdata`: a numeric vector at which to evaluate the polynomial. \( x \) can also be a matrix. Missing values are not allowed in \( x \).
- `degree`: the degree of the polynomial. Must be less than the number of unique points if `raw = TRUE`.
- `coefs`: for prediction, coefficients from a previous fit.
- `raw`: if true, use raw and not orthogonal polynomials.
- `object`: an object inheriting from class "poly", normally the result of a call to `poly` with a single vector argument.
- `...`: further vectors.
- `predict.poly`: arguments to be passed to or from other methods.
Details

Although formally degree should be named (as it follows ...), an unnamed second argument of length 1 will be interpreted as the degree.

The orthogonal polynomial is summarized by the coefficients, which can be used to evaluate it via the three-term recursion given in Kennedy & Gentle (1980, pp. 343–4), and used in the predict part of the code.

poly using ... is just a convenience wrapper for polym. coef is ignored. Conversely, if polym is called with a single argument in ... it is a wrapper for poly.

Value

For poly with a single vector argument:
A matrix with rows corresponding to points in x and columns corresponding to the degree, with attributes "degree" specifying the degrees of the columns and (unless raw = TRUE) "coeffs" which contains the centering and normalization constants used in constructing the orthogonal polynomials. The matrix has given class c("poly", "matrix").

For poly and polym with more than one input, and predict.poly: a matrix.

Note

This routine is intended for statistical purposes such as contr.poly: it does not attempt to orthogonalize to machine accuracy.

References

See Also

contr.poly.
cars for an example of polynomial regression.

Examples

```r
od <- options(digits = 3) # avoid too much visual clutter
(z <- poly(1:10, 3))
predict(z, seq(2, 4, 0.5))
zapsmall(poly(seq(4, 6, 0.5), 3, coefs = attr(z, "coeffs")))

zapsmall(polym(1:4, c(1, 4:6), degree = 3)) # or just poly()
zapsmall(poly(cbind(1:4, c(1, 4:6)), degree = 3))
options(od)
```
Create a Power Link Object

Description

Creates a link object based on the link function $\eta = \mu^\lambda$.

Usage

```r
power(lambda = 1)
```

Arguments

- `lambda` : a real number.

Details

If `lambda` is non-positive, it is taken as zero, and the log link is obtained. The default `lambda = 1` gives the identity link.

Value

A list with components `linkfun`, `linkinv`, `mu.eta`, and `valideta`. See `make.link` for information on their meaning.

References

See Also

- `make.link`, `family`
- To raise a number to a power, see *Arithmetic*.
- To calculate the power of a test, see various functions in the *stats* package, e.g., `power.t.test`.

Examples

```r
power()
quasi(link = power(1/3))[[c("linkfun", "linkinv")]]
```
power.anova.test  Power Calculations for Balanced One-Way Analysis of Variance Tests

Description

Compute power of test or determine parameters to obtain target power.

Usage

```r
power.anova.test(groups = NULL, n = NULL,
                  between.var = NULL, within.var = NULL,
                  sig.level = 0.05, power = NULL)
```

Arguments

- `groups` Number of groups
- `n` Number of observations (per group)
- `between.var` Between group variance
- `within.var` Within group variance
- `sig.level` Significance level (Type I error probability)
- `power` Power of test (1 minus Type II error probability)

Details

Exactly one of the parameters `groups`, `n`, `between.var`, `power`, `within.var`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that `sig.level` has non-NULL default so `NULL` must be explicitly passed if you want it computed.

Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

Note

`unroot` is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

Author(s)

Claus Ekstrøm

See Also

`anova`, `lm`, `unroot`
Examples

```r
cpyrop.test(groups = 4, n = 5, between.var = 1, within.var = 3)
# Power = 0.3535594

ncpyrop.test(groups = 4, between.var = 1, within.var = 3, power = .80)
# n = 11.92613

## Assume we have prior knowledge of the group means:
groupmeans <- c(120, 130, 140, 150)
cpyrop.test(groups = length(groupmeans),
  between.var = var(groupmeans),
  within.var = 500, power = .90) # n = 15.18834
```

Description

Compute the power of the two-sample test for proportions, or determine parameters to obtain a target power.

Usage

```r
ncpyrop.test(n = NULL, p1 = NULL, p2 = NULL, sig.level = 0.05, power = NULL,
  alternative = c("two.sided", "one.sided"),
  strict = FALSE, tol = .Machine$double.eps^0.25)
```

Arguments

- `n`: number of observations (per group)
- `p1`: probability in one group
- `p2`: probability in other group
- `sig.level`: significance level (Type I error probability)
- `power`: power of test (1 minus Type II error probability)
- `alternative`: one- or two-sided test
- `strict`: use strict interpretation in two-sided case
- `tol`: numerical tolerance used in root finding, the default providing (at least) four significant digits.

Details

Exactly one of the parameters `n`, `p1`, `p2`, `power`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that `sig.level` has a non-NULL default so `NULL` must be explicitly passed if you want it computed.

If `strict = TRUE` is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.
Description

Compute the power of the one- or two-sample t test, or determine parameters to obtain a target power.

Usage

```
power.t.test(n = NULL, delta = NULL, sd = 1, sig.level = 0.05, power = NULL, type = c("two.sample", "one.sample", "paired"), alternative = c("two.sided", "one.sided"), strict = FALSE, tol = .Machine$double.eps*0.25)
```

Arguments

- **n**: number of observations (per group)
- **delta**: true difference in means
- **sd**: standard deviation
- **sig.level**: significance level (Type I error probability)
- **power**: power of test (1 minus Type II error probability)
PP.test

- **type**: string specifying the type of test
- **alternative**: one- or two-sided test
- **strict**: use strict interpretation in two-sided case
- **tol**: numerical tolerance used in root finding, the default providing (at least) four significant digits.

**Details**

Exactly one of the parameters \( n \), \( \delta \), power, sd, and sig.level must be passed as NULL, and that parameter is determined from the others. Notice that the last two have non-NULL defaults, so NULL must be explicitly passed if you want to compute them.

If `strict = TRUE` is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

**Value**

Object of class "power.htest", a list of the arguments (including the computed one) augmented with `method` and `note` elements.

**Note**

`uniroot` is used to solve the power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

**Author(s)**

Peter Dalgaard. Based on previous work by Claus Ekstrøm

**See Also**

`t.test, uniroot`

**Examples**

```r
power.t.test(n = 20, delta = 1)
power.t.test(power = .90, delta = 1)
power.t.test(power = .90, delta = 1, alternative = "one.sided")
```

---

**Description**

Computes the Phillips-Perron test for the null hypothesis that \( x \) has a unit root against a stationary alternative.

**Usage**

```r
PP.test(x, lshort = TRUE)
```
Arguments

- **x**: a numeric vector or univariate time series.
- **short**: a logical indicating whether the short or long version of the truncation lag parameter is used.

Details

The general regression equation which incorporates a constant and a linear trend is used and the corrected t-statistic for a first order autoregressive coefficient equals one is computed. To estimate $\sigma^2$ the Newey-West estimator is used. If `short` is `TRUE`, then the truncation lag parameter is set to $\text{trunc}(4 \times (n/100)^{0.25})$, otherwise $\text{trunc}(12 \times (n/100)^{0.25})$ is used. The p-values are interpolated from Table 4.2, page 103 of Banerjee *et al* (1993).

Missing values are not handled.

Value

A list with class "htest" containing the following components:

- **statistic**: the value of the test statistic.
- **parameter**: the truncation lag parameter.
- **p.value**: the p-value of the test.
- **method**: a character string indicating what type of test was performed.
- **data.name**: a character string giving the name of the data.

Author(s)

A. Trapletti

References

Examples

```r
x <- rnorm(1000)
PP.test(x)
y <- cumsum(x) # has unit root
PP.test(y)
```
Ordinates for Probability Plotting

Description

Generates the sequence of probability points \((1:m - a)/(m + (1-a)-a)\) where \(m\) is either \(n\), if \(\text{length}(n) == 1\), or \(\text{length}(n)\).

Usage

\[
\text{ppoints}(n, a = \text{ifelse}(n <= 10, 3/8, 1/2))
\]

Arguments

- \(n\) either the number of points generated or a vector of observations.
- \(a\) the offset fraction to be used; typically in \((0, 1)\).

Details

If \(0 < a < 1\), the resulting values are within \((0,1)\) (excluding boundaries). In any case, the resulting sequence is symmetric in \([0, 1]\), i.e., \(p + \text{rev}(p) == 1\).

\text{ppoints()}\ is used in \text{qqplot} and \text{qqnorm} to generate the set of probabilities at which to evaluate the inverse distribution.

The choice of \(a\) follows the documentation of the function of the same name in Becker et al (1988), and appears to have been motivated by results from Blom (1958) on approximations to expect normal order statistics (see also \text{quantile}).

References

See Also

\text{qqplot, qqnorm}.

Examples

\[
\text{ppoints(4)} \# \text{the same as } \text{ppoints(1:4)}
\]
\[
\text{ppoints(10)}
\]
\[
\text{ppoints(10, a = 1/2)}
\]
Description

Fit a projection pursuit regression model.

Usage

```r
ppr(x, ...)  
## S3 method for class 'formula'
ppr(formula, data, weights, subset, na.action,
    contrasts = NULL, ..., model = FALSE)

## Default S3 method:
ppr(x, y, weights = rep(1, n),
    ww = rep(1, q), nterms, max.terms = nterms, optlevel = 2,
    sm.method = c("supsmu", "spline", "gcvspath"),
    bass = 0, span = 0, df = 5, gcvp = 1, ...)
```

Arguments

- `formula`: a formula specifying one or more numeric response variables and the explanatory variables.
- `x`: numeric matrix of explanatory variables. Rows represent observations, and columns represent variables. Missing values are not accepted.
- `y`: numeric matrix of response variables. Rows represent observations, and columns represent variables. Missing values are not accepted.
- `nterms`: number of terms to include in the final model.
- `data`: a data frame (or similar: see `model.frame`) from which variables specified in `formula` are preferentially to be taken.
- `weights`: a vector of weights `w_i` for each `case`.
- `ww`: a vector of weights for each `response`, so the fit criterion is the sum over case `i` and responses `j` of `w_ij * (y_ij - fit_ij)^2` divided by the sum of `w_i`.
- `subset`: an index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
- `na.action`: a function to specify the action to be taken if `NAs` are found. The default action is given by `getOption("na.action"). (NOTE: If given, this argument must be named.)
- `contrasts`: the contrasts to be used when any factor explanatory variables are coded.
- `max.terms`: integer from 0 to 3 which determines the thoroughness of an optimization routine in the SMART program. See the ‘Details’ section.
- `optlevel`: the method used for smoothing the ridge functions. The default is to use Friedman’s super smoother `supsmu`. The alternatives are to use the smoothing spline code underlying `smooth.spline`, either with a specified (equivalent) degrees of freedom for each ridge functions, or to allow the smoothness to be chosen by GCV.
bass  super smoother bass tone control used with automatic span selection (see supsmu); the range of values is 0 to 10, with larger values resulting in increased smoothing.

span  super smoother span control (see supsmu). The default, 0, results in automatic span selection by local cross validation. span can also take a value in (0, 1].

df  if sm.method is "spline" specifies the smoothness of each ridge term via the requested equivalent degrees of freedom.

gcvpen  if sm.method is "gcvspline" this is the penalty used in the GCV selection for each degree of freedom used.

...  arguments to be passed to or from other methods.

model  logical. If true, the model frame is returned.

Details

The basic method is given by Friedman (1984), and is essentially the same code used by S-PLUS's pprg. This code is extremely sensitive to the compiler used.

The algorithm first adds up to max. terms ridge terms one at a time; it will use less if it is unable to find a term to add that makes sufficient difference. It then removes the least important term at each step until nterms terms are left.

The levels of optimization (argument optlevel) differ in how thoroughly the models are refitted during this process. At level 0 the existing ridge terms are not refitted. At level 1 the projection directions are not refitted, but the ridge functions and the regression coefficients are.

Levels 2 and 3 refit all the terms and are equivalent for one response; level 3 is more careful to re-balance the contributions from each regressor at each step and so is a little less likely to converge to a saddle point of the sum of squares criterion.

Value

A list with the following components, many of which are for use by the method functions.

call  the matched call

p  the number of explanatory variables (after any coding)

q  the number of response variables

mu  the argument nterms

m  the argument max.terms

gof  the overall residual (weighted) sum of squares for the selected model

gofn  the overall residual (weighted) sum of squares against the number of terms, up to max. terms. Will be invalid (and zero) for less than nterms.

df  the argument df

edf  if sm.method is "spline" or "gcvspline" the equivalent number of degrees of freedom for each ridge term used.

xnames  the names of the explanatory variables

ynames  the names of the response variables

alpha  a matrix of the projection directions, with a column for each ridge term

beta  a matrix of the coefficients applied for each response to the ridge terms: the rows are the responses and the columns the ridge terms

yb  the weighted means of each response
the overall scale factor used: internally the responses are divided by ys to have unit total weighted sum of squares.

fitted.values  the fitted values, as a matrix if q > 1.

residuals       the residuals, as a matrix if q > 1.

smod           internal work array, which includes the ridge functions evaluated at the training set points.

model          (only if model = TRUE) the model frame.

Source

Friedman (1984): converted to double precision and added interface to smoothing splines by B. D. Ripley, originally for the MASS package.

prcomp

Principal Components Analysis

Description

Performs a principal components analysis on the given data matrix and returns the results as an object of class `prcomp`.

Usage

```r
prcomp(x, ...)

## S3 method for class 'formula'
prcomp(formula, data = NULL, subset, na.action, ...)

## Default S3 method:
prcomp(x, retx = TRUE, center = TRUE, scale. = FALSE,
       tol = NULL, ...)

## S3 method for class 'prcomp'
predict(object, newdata, ...)
```

Arguments

- `formula` a formula with no response variable, referring only to numeric variables.
- `data` an optional data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- `subset` an optional vector used to select rows (observations) of the data matrix `x`.
- `na.action` a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The `factory-fresh` default is `na.omit`.
- `...` arguments passed to or from other methods. If `x` is a formula one might specify `scale.` or `tol`.
- `x` a numeric or complex matrix (or data frame) which provides the data for the principal components analysis.
- `retx` a logical value indicating whether the rotated variables should be returned.
- `center` a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of `x` can be supplied. The value is passed to `scale`.
scale.  a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is FALSE for consistency with S, but in general scaling is advisable. Alternatively, a vector of length equal to the number of columns of x can be supplied. The value is passed to scale.

tol  a value indicating the magnitude below which components should be omitted. (Components are omitted if their standard deviations are less than or equal to tol times the standard deviation of the first component.) With the default null setting, no components are omitted. Other settings for tol could be tol = 0 or tol = sqrt(.Machine$double.eps), which would omit essentially constant components.

object  Object of class inheriting from "prcomp"

newdata  An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, newdata must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

Details

The calculation is done by a singular value decomposition of the (centered and possibly scaled) data matrix, not by using eigen on the covariance matrix. This is generally the preferred method for numerical accuracy. The print method for these objects prints the results in a nice format and the plot method produces a scree plot.

Unlike princomp, variances are computed with the usual divisor $N - 1$.

Note that scale = TRUE cannot be used if there are zero or constant (for center = TRUE) variables.

Value

prcomp returns a list with class "prcomp" containing the following components:

- **sdev**  the standard deviations of the principal components (i.e., the square roots of the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix).

- **rotation**  the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). The function princomp returns this in the element loadings.

- **x**  if retx is true the value of the rotated data (the centred (and scaled if requested) data multiplied by the rotation matrix) is returned. Hence, cov(x) is the diagonal matrix diag(sdev^2). For the formula method, napredict() is applied to handle the treatment of values omitted by the na.action.

- **center**, **scale**  the centering and scaling used, or FALSE.

Note

The signs of the columns of the rotation matrix are arbitrary, and so may differ between different programs for PCA, and even between different builds of R.

Predict Model Predictions

Description
   predict is a generic function for predictions from the results of various model fitting functions. The function invokes particular methods which depend on the class of the first argument.

Usage
   predict (object, ...)

Arguments
   object  a model object for which prediction is desired.
   ...     additional arguments affecting the predictions produced.

Details
   Most prediction methods which are similar to those for linear models have an argument newdata specifying the first place to look for explanatory variables to be used for prediction. Some considerable attempts are made to match up the columns in newdata to those used for fitting, for example that they are of comparable types and that any factors have the same level set in the same order (or can be transformed to be so).
   Time series prediction methods in package stats have an argument n.ahead specifying how many time steps ahead to predict.
   Many methods have a logical argument se.fit saying if standard errors are to returned.

Value
   The form of the value returned by predict depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

`predict.glm, predict.lm, predict.loess, predict.nls, predict.poly, predict.princomp, predict.smooth.spline`

`SafePrediction` for prediction from (univariable) polynomial and spline fits.

Examples

```r
require(utils)

## All the "predict" methods found
## NB most of the methods in the standard packages are hidden.
for(fn in methods("predict"))
  try(
    f <- eval(substitute(getAnywhere(fn)$objs[[1]]), list(fn = fn))
    cat(fn, ":\n\t", deparse(args(f)), "\n")
  )
```

---

**predict.Arima**

*Forecast from ARIMA fits*

Description

Forecast from models fitted by `arima`.

Usage

```r
## S3 method for class 'Arima'
predict(object, n.ahead = 1, newxreg = NULL,
         se.fit = TRUE, ...)
```

Arguments

- `object` The result of an `arima` fit.
- `n.ahead` The number of steps ahead for which prediction is required.
- `newxreg` New values of `xreg` to be used for prediction. Must have at least `n.ahead` rows.
- `se.fit` Logical: should standard errors of prediction be returned?
- `...` arguments passed to or from other methods.

Details

Finite-history prediction is used, via `KalmanForecast`. This is only statistically efficient if the MA part of the fit is invertible, so `predict.Arima` will give a warning for non-invertible MA models.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients. According to Harvey (1993, pp. 58–9) the effect is small.
Value

A time series of predictions, or if se.fit = TRUE, a list with components pred, the predictions, and se, the estimated standard errors. Both components are time series.

References

arima

Examples

```r
od <- options(digits = 5) # avoid too much spurious accuracy
predict(arima(1h, order = c(3,0,0)), n.ahead = 12)

(fit <- arima(USAccDeaths, order = c(0,1,1),
seasonal = list(order = c(0,1,1))))
predict(fit, n.ahead = 6)
options(od)
```

predict.glm

Predict Method for GLM Fits

Description

Obtains predictions and optionally estimates standard errors of those predictions from a fitted generalized linear model object.

Usage

```r
## S3 method for class 'glm'
predict(object, newdata = NULL,
        type = c("link", "response", "terms"),
        se.fit = FALSE, dispersion = NULL, terms = NULL,
        na.action = na.pass, ...)
```

Arguments

- **object**: a fitted object of class inheriting from "glm".
- **newdata**: optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.
predict.glm

type

the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities. The "terms" option returns a matrix giving the fitted values of each term in the model formula on the linear predictor scale.

The value of this argument can be abbreviated.

se.fit

logical switch indicating if standard errors are required.

dispersion

the dispersion of the GLM fit to be assumed in computing the standard errors. If omitted, that returned by summary applied to the object is used.

terms

with type = "terms" by default all terms are returned. A character vector specifies which terms are to be returned

na.action

function determining what should be done with missing values in newdata. The default is to predict NA.

... further arguments passed to or from other methods.

Details

If newdata is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear (in predictions and standard errors), with residual value NA. See also napredict.

Value

If se.fit = FALSE, a vector or matrix of predictions. For type = "terms" this is a matrix with a column per term, and may have an attribute "constant".

If se.fit = TRUE, a list with components

fit

Predictions, as for se.fit = FALSE.

se.fit

Estimated standard errors.

residual.scale

A scalar giving the square root of the dispersion used in computing the standard errors.

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

predict.HoltWinters  Prediction Function for Fitted Holt-Winters Models

Description
Computes predictions and prediction intervals for models fitted by the Holt-Winters method.

Usage
## S3 method for class 'HoltWinters'
predict(object, n.ahead = 1, prediction.interval = FALSE,
   level = 0.95, ...)

Arguments

object  An object of class HoltWinters.
n.ahead  Number of future periods to predict.
prediction.interval  logical. If TRUE, the lower and upper bounds of the corresponding prediction
   intervals are computed.
level  Confidence level for the prediction interval.
...  arguments passed to or from other methods.

Value
A time series of the predicted values. If prediction intervals are requested, a multiple time series
is returned with columns fit, lwr and upr for the predicted values and the lower and upper bounds
respectively.

```

---

**predict.lm**  
*Predict method for Linear Model Fits*

Description

Predicted values based on linear model object.

Usage

```r
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
       interval = c("none", "confidence", "prediction"),
       level = 0.95, type = c("response", "terms"),
       terms = NULL, na.action = na.pass,
       pred.var = res.var/weights, weights = 1, ...)
```

Arguments

- **object**: Object of class inheriting from "lm"
- **newdata**: An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.
- **se.fit**: A switch indicating if standard errors are required.
- **scale**: Scale parameter for std.err. calculation.
- **df**: Degrees of freedom for scale.
- **interval**: Type of interval calculation.
- **level**: Tolerance/confidence level.
- **type**: Type of prediction (response or model term).
- **terms**: If `type` = "terms", which terms (default is all terms), a character vector.
- **na.action**: function determining what should be done with missing values in newdata. The default is to predict NA.
predict.lm

pred.var the variance(s) for future observations to be assumed for prediction intervals. See ‘Details’.

weights variance weights for prediction. This can be a numeric vector or a one-sided model formula. In the latter case, it is interpreted as an expression evaluated in newdata.

... further arguments passed to or from other methods.

Details

predict.lm produces predicted values, obtained by evaluating the regression function in the frame newdata (which defaults to model.frame(object)). If the logical se.fit is TRUE, standard errors of the predictions are calculated. If the numeric argument scale is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting intervals specifies computation of confidence or prediction (tolerance) intervals at the specified level, sometimes referred to as narrow vs. wide intervals.

If the fit is rank-deficient, some of the columns of the design matrix will have been dropped. Prediction from such a fit only makes sense if newdata is contained in the same subspace as the original data. That cannot be checked accurately, so a warning is issued.

If newdata is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit are handled is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the predictions, whereas if na.action = na.exclude they will appear (in predictions, standard errors or interval limits), with value NA. See also napredict.

The prediction intervals are for a single observation at each case in newdata (or by default, the data used for the fit) with error variance(s) pred.var. This can be a multiple of res.var, the estimated value of \( \sigma^2 \); the default is to assume that future observations have the same error variance as those used for fitting. If weights is supplied, the inverse of this is used as a scale factor. For a weighted fit, if the prediction is for the original data frame, weights defaults to the weights used for the model fit, with a warning since it might not be the intended result. If the fit was weighted and newdata is given, the default is to assume constant prediction variance, with a warning.

Value

predict.lm produces a vector of predictions or a matrix of predictions and bounds with column names fit, lwr, and upr if interval is set. For type = "terms" this is a matrix with a column per term and may have an attribute "constant".

If se.fit is TRUE, a list with the following components is returned:

fit vector or matrix as above
se.fit standard error of predicted means
residual.scale residual standard deviations
df degrees of freedom for residual

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

Notice that prediction variances and prediction intervals always refer to future observations, possibly corresponding to the same predictors as used for the fit. The variance of the residuals will be smaller.
Strictly speaking, the formula used for prediction limits assumes that the degrees of freedom for the fit are the same as those for the residual variance. This may not be the case if \texttt{res.var} is not obtained from the fit.

\textbf{See Also}

The model fitting function \texttt{lm, predict. SafePrediction} for prediction from (univariable) polynomial and spline fits.

\textbf{Examples}

```r
require(graphics)

## Predictions
x <- rnorm(15)
y <- x + rnorm(15)
predict(lm(y ~ x))
new <- data.frame(x = seq(-3, 3, 0.5))
predict(lm(y ~ x), new, se.fit = TRUE)
pred.w.plim <- predict(lm(y ~ x), new, interval = "prediction")
pred.w.clim <- predict(lm(y ~ x), new, interval = "confidence")
matplot(new$x, cbind(pred.w.clim, pred.w.plim[,1]),
  lty = c(1,2,2,3,3), type = "l", ylab = "predicted y")

## Prediction intervals, special cases
## The first three of these throw warnings
w <- 1 + x^2
fit <- lm(y ~ x)
wfit <- lm(y ~ x, weights = w)
predict(fit, interval = "prediction")
predict(wfit, interval = "prediction")
predict(wfit, new, interval = "prediction")
predict(wfit, new, interval = "prediction", weights = (new$x)^2)
predict(wfit, new, interval = "prediction", weights = -x^2)

##-- From aov(. ) example ---- predict(. terms)
npk.aov <- aov(yield ~ block + N*P*K, npk)
(termL <- attr(terms(npk.aov), "term.labels"))
(pt <- predict(npk.aov, type = "terms"))
pt. <- predict(npk.aov, type = "terms", terms = termL[1:4])
stopifnot(all.equal(pt[,1:4], pt,
  tolerance = 1e-12, check.attributes = FALSE))

predict.loess

\textit{Predict Loess Curve or Surface}

\textbf{Description}

Predictions from a \texttt{loess} fit, optionally with standard errors.

\textbf{Usage}

```r
## S3 method for class 'loess'
predict(object, newdata = NULL, se = FALSE,
  na.action = na.pass, ...)
```
predict.loess

Arguments

- **object**: an object fitted by `loess`.
- **newdata**: an optional data frame in which to look for variables with which to predict, or a matrix or vector containing exactly the variables needed for prediction. If missing, the original data points are used.
- **se**: should standard errors be computed?
- **na.action**: function determining what should be done with missing values in data frame `newdata`. The default is to predict NA.
- **...**: arguments passed to or from other methods.

Details

The standard errors calculation is slower than prediction.

When the fit was made using `surface = "interpolate"` (the default), `predict.loess` will not extrapolate – so points outside an axis-aligned hypercube enclosing the original data will have missing (NA) predictions and standard errors.

Value

If `se = FALSE`, a vector giving the prediction for each row of `newdata` (or the original data). If `se = TRUE`, a list containing components

- **fit**: the predicted values.
- **se**: an estimated standard error for each predicted value.
- **residual.scale**: the estimated scale of the residuals used in computing the standard errors.
- **df**: an estimate of the effective degrees of freedom used in estimating the residual scale, intended for use with t-based confidence intervals.

If `newdata` was the result of a call to `expand.grid`, the predictions (and s.e.’s if requested) will be an array of the appropriate dimensions.

Predictions from infinite inputs will be NA since `loess` does not support extrapolation.

Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

Author(s)

B. D. Ripley, based on the `cloess` package of Cleveland, Grosse and Shyu.

Examples

cars.lo <- loess(dist ~ speed, cars)
predict(cars.lo, data.frame(speed = seq(5, 30, 1)), se = TRUE)
# to get extrapolation

cars.lo2 <- loess(dist ~ speed, cars,
control = loess.control(surface = "direct"))
predict(cars.lo2, data.frame(speed = seq(5, 30, 1)), se = TRUE)

predict.nls

Predicting from Nonlinear Least Squares Fits

Description

predict.nls produces predicted values, obtained by evaluating the regression function in the frame newdata. If the logical se.fit is TRUE, standard errors of the predictions are calculated. If the numeric argument scale is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting intervals specifies computation of confidence or prediction (tolerance) intervals at the specified level.

At present se.fit and interval are ignored.

Usage

## S3 method for class 'nls'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf, interval = c("none", "confidence", "prediction"), level = 0.95, ...)

Arguments

object An object that inherits from class nls.
newdata A named list or data frame in which to look for variables with which to predict. If newdata is missing the fitted values at the original data points are returned.
se.fit A logical value indicating if the standard errors of the predictions should be calculated. Defaults to FALSE. At present this argument is ignored.
scale A numeric scalar. If it is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this information is extracted from the model fit. At present this argument is ignored.
df A positive numeric scalar giving the number of degrees of freedom for the scale estimate. At present this argument is ignored.
interval A character string indicating if prediction intervals or a confidence interval on the mean responses are to be calculated. At present this argument is ignored.
level A numeric scalar between 0 and 1 giving the confidence level for the intervals (if any) to be calculated. At present this argument is ignored.
... Additional optional arguments. At present no optional arguments are used.
Value

predict.nls produces a vector of predictions. When implemented, interval will produce a matrix of predictions and bounds with column names fit, lwr, and upr. When implemented, if se.fit is TRUE, a list with the following components will be returned:

- fit: vector or matrix as above
- se.fit: standard error of predictions
- residual.scale: residual standard deviations
- df: degrees of freedom for residual

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

mtext("Difference quotient approx. (last)", col = "blue")
lines(pp <- predict(cars.spl, xx, deriv = d), col = "red")
}
points(kn, pp$y[i.kn], pch = 3, col = "dark red")
abline(h = 0, lty = 3, col = "gray")
}
detach(); par(op)
```

preplot

Description

Compute an object to be used for plots relating to the given model object.

Usage

preplot(object, ...)

Arguments

object a fitted model object.
...
additional arguments for specific methods.

Details

Only the generic function is currently provided in base R, but some add-on packages have methods. Principally here for S compatibility.

Value

An object set up to make a plot that describes object.

princomp

Description

princomp performs a principal components analysis on the given numeric data matrix and returns the results as an object of class princomp.

Usage

princomp(x, ...)

## S3 method for class 'formula'
princomp(formula, data = NULL, subset, na.action, ...)

## Default S3 method:
princomp(x, cor = FALSE, scores = TRUE, covmat = NULL,
    subset = rep_len(TRUE, nrow(as.matrix(x))), ...)

## S3 method for class 'princomp'
predict(object, newdata, ...)
princomp

Arguments

- **formula**: a formula with no response variable, referring only to numeric variables.
- **data**: an optional data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector used to select rows (observations) of the data matrix `x`.
- **na.action**: a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The ‘factory-fresh’ default is `na.omit`.
- **x**: a numeric matrix or data frame which provides the data for the principal components analysis.
- **cor**: a logical value indicating whether the calculation should use the correlation matrix or the covariance matrix. (The correlation matrix can only be used if there are no constant variables.)
- **scores**: a logical value indicating whether the score on each principal component should be calculated.
- **covmat**: a covariance matrix, or a covariance list as returned by `cov.wt` (and `cov.mve` or `cov.mcd` from package `MASS`). If supplied, this is used rather than the covariance matrix of `x`.
- **...**: arguments passed to or from other methods. If `x` is a formula one might specify `cor` or `scores`.
- **object**: Object of class inheriting from "princomp"
- **newdata**: An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, `newdata` must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

Details

`princomp` is a generic function with "formula" and "default" methods.

The calculation is done using `eigen` on the correlation or covariance matrix, as determined by `cor`. This is done for compatibility with the S-PLUS result. A preferred method of calculation is to use `svd` on `x`, as is done in `prcomp`.

Note that the default calculation uses divisor `n` for the covariance matrix.

The `print` method for these objects prints the results in a nice format and the `plot` method produces a scree plot (`screeplot`). There is also a `biplot` method.

If `x` is a formula then the standard NA-handling is applied to the scores (if requested): see `napredict`.

`princomp` only handles so-called R-mode PCA, that is feature extraction of variables. If a data matrix is supplied (possibly via a formula) it is required that there are at least as many units as variables. For Q-mode PCA use `prcomp`.

Value

`princomp` returns a list with class "princomp" containing the following components:

- **sdev**: the standard deviations of the principal components.
princomp

loadings  the matrix of variable loadings (i.e., a matrix whose columns contain the eigen-
vectors). This is of class "loadings": see loadings for its print method.

center  the means that were subtracted.

scale  the scalings applied to each variable.

n.obs  the number of observations.

scores  if scores = TRUE, the scores of the supplied data on the principal components.
These are non-null only if x was supplied, and if covmat was also supplied if it was a covariance list. For the formula method, napredict() is applied to handle the treatment of values omitted by the na.action.

call  the matched call.

na.action  If relevant.

Note

The signs of the columns of the loadings and scores are arbitrary, and so may differ between different programs for PCA, and even between different builds of R.

```r
(pc.cl <- princomp(stackloss))
```

## Robust

```r
(pc.rob <- princomp(stackloss, covmat = MASS::cov.rob(stackloss)))
```

---

### Description

Print object of class "power.htest" in nice layout.

### Usage

```r
## S3 method for class 'power.htest'
print(x, ...)
```

### Arguments

- **x**: Object of class "power.htest".
- **...**: further arguments to be passed to or from methods.

### Details

A `power.htest` object is just a named list of numbers and character strings, supplemented with method and note elements. The method is displayed as a title, the note as a footnote, and the remaining elements are given in an aligned `name = value` format.

### Value

- none

### Author(s)

Peter Dalgaard

- `power.t.test`, `power.prop.test`
Description

Notably for calendar related time series objects, `format` and `print` methods showing years, months and or quarters respectively.

Usage

```r
## S3 method for class 'ts'
print(x, calendar, ...)
```

Arguments

- `x`: a time series object.
- `calendar`: enable/disable the display of information about month names, quarter names or year when printing. The default is `TRUE` for a frequency of 4 or 12, `FALSE` otherwise.
- `...`: additional arguments to `print` (or `format` methods).

Details

The `print` method for "ts" objects prints a header (basically of `tsp(x)`), if `calendar` is false, and then prints the result of `.preformat.ts(x, *)`, which is typically a `matrix` with `rownames` built from the calendar times where applicable.

See Also

`print, ts`.

Examples

```r
print(ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)
print(sunspot.1 <- window(sunspot.month, end=c(1756, 12)))
m <- .preformat.ts(sunspot.1) # a character matrix
```

---

**printCoefmat**

*Print Coefficient Matrices*

Description

Utility function to be used in higher-level `print` methods, such as those for `summary.lm`, `summary.glm` and `anova`. The goal is to provide a flexible interface with smart defaults such that often, only `x` needs to be specified.
Usage

printCoefmat(x, digits = max(3, getOption("digits") - 2),
        signif.stars = getOption("show.signif.stars"),
        signif.legend = signif.stars,
        dig.tst = max(1, min(5, digits - 1)),
        cs.ind = 1L:k, tst.ind = k + 1L,
        zap.ind = integer(), P.values = NULL,
        has.Pvalue = nc >= 4L &&
        substr(colnames(x)[nc], 1L, 3L) == "Pr(",
        eps.Pvalue = .Machine$double.eps,
        na.print = "NA", ...)

Arguments

x
a numeric matrix like object, to be printed.
digits
minimum number of significant digits to be used for most numbers.
signif.stars
logical; if TRUE, P-values are additionally encoded visually as 'significance
stars' in order to help scanning of long coefficient tables. It defaults to the
show.signif.stars slot of options.
signif.legend
logical; if TRUE, a legend for the 'significance stars' is printed provided
signif.stars = TRUE.
dig.tst
minimum number of significant digits for the test statistics, see tst.ind.
cs.ind
indices (integer) of column numbers which are (like) coefficients and standard
errors to be formatted together.
tst.ind
indices (integer) of column numbers for test statistics.
zap.ind
indices (integer) of column numbers which should be formatted by zapsmall,
i.e., by 'zapping' values close to 0.
P.values
logical or NULL; if TRUE, the last column of x is formatted by format.pval
as P values. If P.values = NULL, the default, it is set to TRUE only if
options("show.coef.PValue") is TRUE and x has at least 4 columns and the
last column name of x starts with "Pr(".
has.Pvalue
logical; if TRUE, the last column of x contains P values; in that case, it is printed
if and only if P.values (above) is true.
eps.Pvalue
number, ...
a.print
a character string to code NA values in printed output.
...
further arguments for print.

Value

Invisibly returns its argument, x.

Author(s)

Martin Maechler

**profile**  
*Generic Function for Profiling Models*

**Description**

Investigates behavior of objective function near the solution represented by `fitted`.

See documentation on method functions for further details.

**Usage**

```r
profile(fitted, ...)
```

**Arguments**

- `fitted`  
  the original fitted model object.
- `...`  
  additional parameters. See documentation on individual methods.

**Value**

A list with an element for each parameter being profiled. See the individual methods for further details.

**See Also**

- `profile.nls`, `profile.glm` in package **MASS**, ...

For profiling R code, see **Rprof**.
Method for Profiling nls Objects

Description

Investigates the profile log-likelihood function for a fitted model of class "nls".

Usage

```r
## S3 method for class 'nls'
profile(fitted, which = 1:npar, maxpts = 100, alphamax = 0.01,
delta.t = cutoff/5, ...)  
```

Arguments

- `fitted` - the original fitted model object.
- `which` - the original model parameters which should be profiled. This can be a numeric or character vector. By default, all non-linear parameters are profiled.
- `maxpts` - maximum number of points to be used for profiling each parameter.
- `alphamax` - highest significance level allowed for the profile t-statistics.
- `delta.t` - suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.
- `...` - further arguments passed to or from other methods.

Details

The profile t-statistics is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

Value

A list with an element for each parameter being profiled. The elements are data-frames with two variables

- `par.vals` - a matrix of parameter values for each fitted model.
- `tau` - the profile t-statistics.

pr1$A
pr1$lrc
# see also example(plot.profile.nls)

Description

proj returns a matrix or list of matrices giving the projections of the data onto the terms of a linear model. It is most frequently used for aov models.

Usage

proj(object, ...)

## S3 method for class 'aov'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

## S3 method for class 'aovlist'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

## Default S3 method:
proj(object, onedf = TRUE, ...)

## S3 method for class 'lm'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

Arguments

object An object of class "lm" or a class inheriting from it, or an object with a similar structure including in particular components qr and effects.

onedf A logical flag. If TRUE, a projection is returned for all the columns of the model matrix. If FALSE, the single-column projections are collapsed by terms of the model (as represented in the analysis of variance table).

unweighted.scale If the fit producing object used weights, this determines if the projections correspond to weighted or unweighted observations.

... Swallow and ignore any other arguments.

Details

A projection is given for each stratum of the object, so for aov models with an Error term the result is a list of projections.
Value

A projection matrix or (for multi-stratum objects) a list of projection matrices.

Each projection is a matrix with a row for each observations and either a column for each term (oneway = FALSE) or for each coefficient (oneway = TRUE). Projection matrices from the default method have orthogonal columns representing the projection of the response onto the column space of the Q matrix from the QR decomposition. The fitted values are the sum of the projections, and the sum of squares for each column is the reduction in sum of squares from fitting that column (after those to the left of it).

The methods for lm and aov models add a column to the projection matrix giving the residuals (the projection of the data onto the orthogonal complement of the model space).

Strictly, when oneway = FALSE the result is not a projection, but the columns represent sums of projections onto the columns of the model matrix corresponding to that term. In this case the matrix does not depend on the coding used.

Author(s)

The design was inspired by the S function of the same name described in Chambers et al (1992).

prop.test

Test of Equal or Given Proportions

Description

prop.test can be used for testing the null that the proportions (probabilities of success) in several groups are the same, or that they equal certain given values.

Usage

prop.test(x, n, p = NULL,
    alternative = c("two.sided", "less", "greater"),
    conf.level = 0.95, correct = TRUE)

Arguments

x a vector of counts of successes, a one-dimensional table with two entries, or a two-dimensional table (or matrix) with 2 columns, giving the counts of successes and failures, respectively.

n a vector of counts of trials; ignored if x is a matrix or a table.

p a vector of probabilities of success. The length of p must be the same as the number of groups specified by x, and its elements must be greater than 0 and less than 1.

alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. Only used for testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.

conf.level confidence level of the returned confidence interval. Must be a single number between 0 and 1. Only used when testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.

correct a logical indicating whether Yates’ continuity correction should be applied where possible.

Details

Only groups with finite numbers of successes and failures are used. Counts of successes and failures must be nonnegative and hence not greater than the corresponding numbers of trials which must be positive. All finite counts should be integers.

If p is NULL and there is more than one group, the null tested is that the proportions in each group are the same. If there are two groups, the alternatives are that the probability of success in the first group is less than, not equal to, or greater than the probability of success in the second group, as specified by alternative. A confidence interval for the difference of proportions with confidence level as specified by conf.level and clipped to [-1, 1] is returned. Continuity correction is used only if it does not exceed the difference of the sample proportions in absolute value. Otherwise, if there are more than 2 groups, the alternative is always "two.sided", the returned confidence interval is NULL, and continuity correction is never used.

If there is only one group, then the null tested is that the underlying probability of success is p, or .5 if p is not given. The alternative is that the probability of success is less than, not equal to, or greater than p or 0.5, respectively, as specified by alternative. A confidence interval for the
underlying proportion with confidence level as specified by conf.level and clipped to \([0, 1]\) is returned. Continuity correction is used only if it does not exceed the difference between sample and null proportions in absolute value. The confidence interval is computed by inverting the score test. Finally, if \(p\) is given and there are more than 2 groups, the null tested is that the underlying probabilities of success are those given by \(p\). The alternative is always "two.sided", the returned confidence interval is NULL, and continuity correction is never used.

### Value

A list with class "htest" containing the following components:

- **statistic**: the value of Pearson's chi-squared test statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- **p.value**: the p-value of the test.
- **estimate**: a vector with the sample proportions \(x/n\).
- **conf.int**: a confidence interval for the true proportion if there is one group, or for the difference in proportions if there are 2 groups and \(p\) is not given, or NULL otherwise. In the cases where it is not NULL, the returned confidence interval has an asymptotic confidence level as specified by conf.level, and is appropriate to the specified alternative hypothesis.
- **null.value**: the value of \(p\) if specified by the null, or NULL otherwise.
- **alternative**: a character string describing the alternative.
- **method**: a character string indicating the method used, and whether Yates’ continuity correction was applied.
- **data.name**: a character string giving the names of the data.

### Examples

```r
heads <- rbinom(1, size = 100, prob = .5)
prop.test(heads, 100)  # continuity correction TRUE by default
prop.test(heads, 100, correct = FALSE)
```

```
## Data from Fleiss (1981), p. 139.
## H0: The null hypothesis is that the four populations from which
## the patients were drawn have the same true proportion of smokers.
## A: The alternative is that this proportion is different in at
## least one of the populations.
```
prop.trend.test

smokers  <-  c(83, 90, 129, 70)
patients  <-  c(86, 93, 136, 82)
prop.test(smokers, patients)

---

prop.trend.test  Test for trend in proportions

Description

Performs chi-squared test for trend in proportions, i.e., a test asymptotically optimal for local alternatives where the log odds vary in proportion with score. By default, score is chosen as the group numbers.

Usage

prop.trend.test(x, n, score = seq_along(x))

Arguments

x  Number of events
n  Number of trials
score  Group score

Value

An object of class "htest" with title, test statistic, p-value, etc.

Note

This really should get integrated with prop.test

Author(s)

Peter Dalgaard

prop.trend.test(smokers, patients)
prop.trend.test(smokers, patients, c(0,0,0,1))
qqnorm

Quantile-Quantile Plots

Description

qqnorm is a generic function the default method of which produces a normal QQ plot of the values in y. qqline adds a line to a “theoretical”, by default normal, quantile-quantile plot which passes through the probs quantiles, by default the first and third quartiles.

qqplot produces a QQ plot of two datasets.

Graphical parameters may be given as arguments to qqnorm, qqplot and qqline.

Usage

qqnorm(y, ...)  
## Default S3 method:
qqnorm(y, ylim, main = "Normal Q-Q Plot",  
       xlab = "Theoretical Quantiles", ylab = "Sample Quantiles",  
       plot.it = TRUE, datax = FALSE, ...)

qqline(y, datax = FALSE, distribution = qnorm,  
       probs = c(0.25, 0.75), qtype = 7, ...)

qqplot(x, y, plot.it = TRUE, xlab = deparse(substitute(x)),  
       ylab = deparse(substitute(y)), ...)

Arguments

x               The first sample for qqplot.
y               The second or only data sample.
xlab, ylab, main  
plot labels. The xlab and ylab refer to the y and x axes respectively if datax = TRUE.
plot.it         logical. Should the result be plotted?
datax            logical. Should data values be on the x-axis?
distribution     quantile function for reference theoretical distribution.
probs            numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.
qtype            the type of quantile computation used in quantile.
ylim, ...        graphical parameters.

Value

For qqnorm and qqplot, a list with components

x               The x coordinates of the points that were/would be plotted
y               The original y vector, i.e., the corresponding y coordinates including NAs.
quade.test

References

ppoints, used by qqnorm to generate approximations to expected order statistics for a normal distribution.

Examples

```r
require(graphics)

y <- rt(200, df = 5)
qqnorm(y); qline(y, col = 2)
qqplot(y, rt(300, df = 5))

qqnorm(precip, ylab = "Precipitation [in/yr] for 70 US cities")

## "QQ-Chisquare" : -----------------------------
y <- rchisq(500, df = 3)
## Q-Q plot for Chi^2 data against true theoretical distribution:
qqplot(qchisq(ppoints(500), df = 3), y, 
   main = expression("Q-Q plot for " ~ \chi^2[nu == 3]))
qline(y, distribution = function(p) qchisq(p, df = 3), 
   prob = c(0.1, 0.6), col = 2)
}

mtext("qline(*, dist = qchisq(., df=3), prob = c(0.1, 0.6))")
```

---

**Quade Test**

Performs a Quade test with unreplicated blocked data.

**Usage**

```r
quade.test(y, ...) 
```

## Default S3 method:
quade.test(y, groups, blocks, ...)

## S3 method for class 'formula'
quade.test(formula, data, subset, na.action, ...)

**Arguments**

- **y**: either a numeric vector of data values, or a data matrix.
- **groups**: a vector giving the group for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.
- **blocks**: a vector giving the block for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.
formula a formula of the form \( a \sim b \mid c \), where \( a, b \) and \( c \) give the data values and corresponding groups and blocks, respectively.

data an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.

... further arguments to be passed to or from methods.

Details

`quade.test` can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in \( y \) for each combination of levels of \( \text{groups} \) and \( \text{blocks} \)) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of \( \text{blocks} \), the location parameter of \( y \) is the same in each of the groups.

If \( y \) is a matrix, \( \text{groups} \) and \( \text{blocks} \) are obtained from the column and row indices, respectively. NA’s are not allowed in \( \text{groups} \) or \( \text{blocks} \); if \( y \) contains NA’s, corresponding blocks are removed.

Value

A list with class "htest" containing the following components:

- statistic the value of Quade’s F statistic.
- parameter a vector with the numerator and denominator degrees of freedom of the approximate F distribution of the test statistic.
- p.value the p-value of the test.
- method the character string "Quade test".
- data.name a character string giving the names of the data.

quade.test(y)

quantile Sample Quantiles

Description
The generic function quantile produces sample quantiles corresponding to the given probabilities.
The smallest observation corresponds to a probability of 0 and the largest to a probability of 1.

Usage
quantile(x, ...)

## Default S3 method:
quantile(x, probs = seq(0, 1, 0.25), na.rm = FALSE,
  names = TRUE, type = 7, ...)

Arguments

x numeric vector whose sample quantiles are wanted, or an object of a class for which a method has been defined (see also ‘details’). NA and NaN values are not allowed in numeric vectors unless na.rm is TRUE.

probs numeric vector of probabilities with values in [0, 1]. (Values up to ‘2e-14’ outside that range are accepted and moved to the nearby endpoint.)

na.rm logical; if true, any NA and NaN’s are removed from x before the quantiles are computed.

names logical; if true, the result has a names attribute. Set to FALSE for speedup with many probs.

type an integer between 1 and 9 selecting one of the nine quantile algorithms detailed below to be used.

... further arguments passed to or from other methods.

Details
A vector of length length(probs) is returned; if names = TRUE, it has a names attribute.
NA and NaN values in probs are propagated to the result.
The default method works with classed objects sufficiently like numeric vectors that sort and (not needed by types 1 and 3) addition of elements and multiplication by a number work correctly. Note that as this is in a namespace, the copy of sort in base will be used, not some S4 generic of that name. Also note that that is no check on the ‘correctly’, and so e.g. quantile can be applied to complex vectors which (apart from ties) will be ordered on their real parts.

There is a method for the date-time classes (see “POSIXt”). Types 1 and 3 can be used for class "Date" and for ordered factors.
quantile returns estimates of underlying distribution quantiles based on one or two order statistics from the supplied elements in x at probabilities in probs. One of the nine quantile algorithms discussed in Hyndman and Fan (1996), selected by type, is employed.

All sample quantiles are defined as weighted averages of consecutive order statistics. Sample quantiles of type $i$ are defined by:

$$Q_i(p) = (1 - \gamma)x_j + \gamma x_{j+1}$$

where $1 \leq i \leq 9$, $\frac{i-m}{n} \leq p < \frac{i-m+1}{n}$, $x_j$ is the $j$th order statistic, $n$ is the sample size, the value of $\gamma$ is a function of $j = \lfloor np + m \rfloor$ and $g = np + m - j$, and $m$ is a constant determined by the sample quantile type.

**Discontinuous sample quantile types 1, 2, and 3**

For types 1, 2 and 3, $Q_i(p)$ is a discontinuous function of $p$, with $m = 0$ when $i = 1$ and $i = 2$, and $m = -1/2$ when $i = 3$.

**Type 1** Inverse of empirical distribution function. $\gamma = 0$ if $g = 0$, and 1 otherwise.

**Type 2** Similar to type 1 but with averaging at discontinuities. $\gamma = 0.5$ if $g = 0$, and 1 otherwise.

**Type 3** SAS definition: nearest even order statistic. $\gamma = 0$ if $g = 0$ and $j$ is even, and 1 otherwise.

**Continuous sample quantile types 4 through 9**

For types 4 through 9, $Q_i(p)$ is a continuous function of $p$, with $\gamma = g$ and $m$ given below. The sample quantiles can be obtained equivalently by linear interpolation between the points $(p_k, x_k)$ where $x_k$ is the $k$th order statistic. Specific expressions for $p_k$ are given below.

**Type 4** $m = 0$. $p_k = \frac{k}{n}$. That is, linear interpolation of the empirical cdf.

**Type 5** $m = 1/2$. $p_k = \frac{k-0.5}{n}$. That is a piecewise linear function where the knots are the values midway through the steps of the empirical cdf. This is popular amongst hydrologists.

**Type 6** $m = p$. $p_k = \frac{k}{n+1}$. Thus $p_k = \mathbb{E}[F(x_k)]$. This is used by Minitab and by SPSS.

**Type 7** $m = 1 - p$. $p_k = \frac{k-1}{n+1}$. In this case, $p_k = \text{mode}[F(x_k)]$. This is used by S.

**Type 8** $m = (p + 1)/3$. $p_k = \frac{k-1/3}{n+1/3}$. Then $p_k \approx \text{median}[F(x_k)]$. The resulting quantile estimates are approximately median-unbiased regardless of the distribution of $x$.

**Type 9** $m = p/4 + 3/8$. $p_k = \frac{k-3/8}{n+3/8}$. The resulting quantile estimates are approximately unbiased for the expected order statistics if $x$ is normally distributed.

Further details are provided in Hyndman and Fan (1996) who recommended type 8. The default method is type 7, as used by S and by R < 2.0.0.

**Author(s)**

of the version used in R >= 2.0.0, Ivan Frohne and Rob J Hyndman.

r2table

Random 2-way Tables with Given Marginals

Description
Generate random 2-way tables with given marginals using Patefield’s algorithm.

Usage
r2table(n, r, c)

Arguments

- **n**
  - a non-negative numeric giving the number of tables to be drawn.

- **r**
  - a non-negative vector of length at least 2 giving the row totals, to be coerced to integer. Must sum to the same as **c**.

- **c**
  - a non-negative vector of length at least 2 giving the column totals, to be coerced to integer.

Value
A list of length **n** containing the generated tables as its components.

References
Examples

```r
## Fisher's Tea Drinker data.
TeaTasting <-
  matrix(c(3, 1, 1, 3),
         nrow = 2,
         dimnames = list(Guess = c("Milk", "Tea"),
                        Truth = c("Milk", "Tea")))
## Simulate permutation test for independence based on the maximum
## Pearson residuals (rather than their sum).
rowTotals <- rowSums(TeaTasting)
colTotals <- colSums(TeaTasting)
noOfCases <- sum(rowTotals)
expected <- outer(rowTotals, colTotals, "*") / noOfCases
maxSqResid <- function(x) max((x - expected) ^ 2 / expected)
simMaxSqResid <-
  sapply(r2dtable(1000, rowTotals, colTotals), maxSqResid)
sum(simMaxSqResid >= maxSqResid(TeaTasting)) / 1000
## Fisher's exact test gives p = 0.4857 ...
```

Description

Read, write and coerce 'flat' contingency tables.

Usage

```r
read.ftable(file, sep = "", quote = "\"",
             row.var.names, col.vars, skip = 0)
write.ftable(x, file = "", quote = TRUE, append = FALSE,
              digits =getOption("digits"), ...)

## S3 method for class 'ftable'
format(x, quote = TRUE, digits =getOption("digits"),
        method = c("non.compact", "row.compact",
                   "col.compact", "compact"),
        lsep = " | ", ...)
## S3 method for class 'ftable'
print(x, digits =getOption("digits"), ...)
```

Arguments

- **file**
either a character string naming a file or a connection which the data are to be read from or written to. "" indicates input from the console for reading and output to the console for writing.

- **sep**
the field separator string. Values on each line of the file are separated by this string.

- **quote**
a character string giving the set of quoting characters for read.ftable; to disable quoting altogether, use quote="". For write.table, a logical indicating whether strings in the data will be surrounded by double quotes.
row.var.names  a character vector with the names of the row variables, in case these cannot be
determined automatically.

col.vars  a list giving the names and levels of the column variables, in case these cannot be
determined automatically.

skip  the number of lines of the data file to skip before beginning to read data.

x  an object of class "ftable".

append  logical. If TRUE and file is the name of a file (and not a connection or "|cmd"),
the output from write.ftable is appended to the file. If FALSE, the contents of
file will be overwritten.

digits  an integer giving the number of significant digits to use for (the cell entries of)
x.

method  string specifying how the "ftable" object is formatted (and printed if used
as in write.ftable() or the print method). Available methods are (see the
examples):

"non.compact"  the default representation of an "ftable" object.

"row.compact"  a row-compact version without empty cells below the column
labels.

"col.compact"  a column-compact version without empty cells to the right of
the row labels.

"compact"  a row- and column-compact version. This may imply a row and a
column label sharing the same cell. They are then separated by the string

"sep"  only for method = "compact", the separation string for row and column labels.

...  further arguments to be passed to or from methods; for write() and print(),
notably arguments such as method, passed to format().

Details

read.ftable reads in a flat-like contingency table from a file. If the file contains the written
representation of a flat table (more precisely, a header with all information on names and levels of
column variables, followed by a line with the names of the row variables), no further arguments are
needed. Similarly, flat tables with only one column variable the name of which is the only entry
in the first line are handled automatically. Other variants can be dealt with by skipping all header
information using skip, and providing the names of the row variables and the names and levels of
the column variable using row.var.names and col.vars, respectively. See the examples below.

Note that flat tables are characterized by their ‘ragged’ display of row (and maybe also column)
labels. If the full grid of levels of the row variables is given, one should instead use read.table to
read in the data, and create the contingency table from this using xtabs.

write.ftable writes a flat table to a file, which is useful for generating ‘pretty’ ASCII representa-
tions of contingency tables. Different versions are available via the method argument, which may
be useful, for example, for constructing LaTeX tables.

## Agresti (1990), page 157, Table 5.8.
## Not in ftable standard format, but o.k.
file <- tempfile()
cat("Intercourse\n",  
"Race Gender Yes No\n",  
"White Male  43 134\n",  
" Female   26 149\n",  
"Black Male  29  23\n",  
" Female   22  36\n",
file = file)
file.show(file)
ft1 <- read.ftable(file)
ft1
unlink(file)

## Agresti (1990), page 297, Table 8.16.
## Almost o.k., but misses the name of the row variable.
file <- tempfile()
cat(" \"Tonsil Size\"\n",  
" \"Not Enl.\" \"Enl.\" \"Greatly Enl.\"\n",  
"Noncarriers  497  560  269\n",  
"Carriers     19   29  24\n",
file = file)
file.show(file)
ft <- read.ftable(file, skip = 2,
  row.var.names = "Status",
  col.vars = list("Tonsil Size" =
                  c("Not Enl.", "Enl.", "Greatly Enl.")))
ft
unlink(file)

ft22 <- ftable(Titanic, row.vars = 2:1, col.vars = 4:3)
write.ftable(ft22, quote = FALSE)
write.ftable(ft22, quote = FALSE, method="row.compact")
write.ftable(ft22, quote = FALSE, method="col.compact")
write.ftable(ft22, quote = FALSE, method="compact")
```

Description

Draws rectangles around the branches of a dendrogram highlighting the corresponding clusters. First the dendrogram is cut at a certain level, then a rectangle is drawn around selected branches.

Usage

```r
rect.hclust(tree, k = NULL, which = NULL, x = NULL, h = NULL,  
        border = 2, cluster = NULL)
```
Arguments

- **tree**: an object of the type produced by `hclust`.
- **k, h**: Scalar. Cut the dendrogram such that either exactly k clusters are produced or by cutting at height h.
- **which, x**: A vector selecting the clusters around which a rectangle should be drawn. which selects clusters by number (from left to right in the tree), x selects clusters containing the respective horizontal coordinates. Default is `which = 1:k`.
- **border**: Vector with border colors for the rectangles.
- **cluster**: Optional vector with cluster memberships as returned by `cutree(hclust.obj, k = k)`, can be specified for efficiency if already computed.

Value

(Invisibly) returns a list where each element contains a vector of data points contained in the respective cluster.

See Also

`hclust`, `identify.hclust`.

Examples

```
require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)
rect.hclust(hca, k = 3, border = "red")
x <- rect.hclust(hca, h = 50, which = c(2,7), border = 3:4)
x
```

---

**relevel**  
*Reorder Levels of Factor*

Description

The levels of a factor are re-ordered so that the level specified by `ref` is first and the others are moved down. This is useful for `contr.treatment` contrasts which take the first level as the reference.

Usage

```
relevel(x, ref, ...)
```

Arguments

- **x**: An unordered factor.
- **ref**: The reference level.
- **...**: Additional arguments for future methods.
reorder.default

Reorder Levels of a Factor

Description

reorder is a generic function. The "default" method treats its first argument as a categorical variable, and reorders its levels based on the values of a second variable, usually numeric.

Usage

reorder(x, ...)  
## Default S3 method:  
reorder(x, X, FUN = mean, ...,  
   order = isordered(x))

Arguments

x An atomic vector, usually a factor (possibly ordered). The vector is treated as a categorical variable whose levels will be reordered. If x is not a factor, its unique values will be used as the implicit levels.

X a vector of the same length as x, whose subset of values for each unique level of x determines the eventual order of that level.

FUN a function whose first argument is a vector and returns a scalar, to be applied to each subset of x determined by the levels of x.

... optional: extra arguments supplied to FUN

order logical, whether return value will be an ordered factor rather than a factor.

Value

A factor or an ordered factor (depending on the value of order), with the order of the levels determined by FUN applied to X grouped by x. The levels are ordered such that the values returned by FUN are in increasing order. Empty levels will be dropped.

Additionally, the values of FUN applied to the subsets of X (in the original order of the levels of x) is returned as the "scores" attribute.

Examples

warpbreaks$tension <- relevel(warpbreaks$tension, ref = "M")  
summary(lm(breaks ~ wool + tension, data = warpbreaks))

1508

Value

A factor of the same length as x.

See Also

factor, contr.treatment, levels, reorder.

Examples

warpbreaks$tension <- relevel(warpbreaks$tension, ref = "M")  
summary(lm(breaks ~ wool + tension, data = warpbreaks))

**reorder.dendrogram**

**Author(s)**

Deepayan Sarkar <deepayan.sarkar@r-project.org>

**See Also**

reorder.dendrogram, levels, relevel.

**Examples**

```r
require(graphics)

bymedian <- with(InsectSprays, reorder(spray, count, median))
boxplot(count ~ bymedian, data = InsectSprays,
       xlab = "Type of spray", ylab = "Insect count",
       main = "InsectSprays data", varwidth = TRUE,
       col = "lightgray")
```

**reorder.dendrogram**  
*Reorder a Dendrogram*

**Description**

A method for the generic function reorder.

There are many different orderings of a dendrogram that are consistent with the structure imposed. This function takes a dendrogram and a vector of values and reorders the dendrogram in the order of the supplied vector, maintaining the constraints on the dendrogram.

**Usage**

```r
## S3 method for class 'dendrogram'
reorder(x, wts, agglo.FUN = sum, ...)
```

**Arguments**

- `x`  
  the (dendrogram) object to be reordered
- `wts`  
  numeric weights (arbitrary values) for reordering.
- `agglo.FUN`  
  a function for weights agglomeration, see below.
- `...`  
  additional arguments

**Details**

Using the weights `wts`, the leaves of the dendrogram are reordered so as to be in an order as consistent as possible with the weights. At each node, the branches are ordered in increasing weights where the weight of a branch is defined as \( f(w_j) \) where \( f \) is `agglo.FUN` and \( w_j \) is the weight of the \( j \)-th sub branch.

**Value**

A dendrogram where each node has a further attribute value with its corresponding weight.
replications

Author(s)
R. Gentleman and M. Maechler

reorder.
rev.dendrogram which simply reverses the nodes’ order; heatmap, cophenetic.

Examples

require(graphics)
set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
dd <- as.dendrogram(hc)
dd.reorder <- reorder(dd, 10:1)
plot(dd, main = "random dendrogram 'dd'")
op <- par(mfcol = 1:2)
plot(dd.reorder, main = "reorder(dd, 10:1)")
plot(reorder(dd, 10:1, agglo.FUN = mean), main = "reorder(dd, 10:1, mean)")
par(op)

<table>
<thead>
<tr>
<th>replications</th>
<th>Number of Replications of Terms</th>
</tr>
</thead>
</table>

Description
Returns a vector or a list of the number of replicates for each term in the formula.

Usage
replications(formula, data = NULL, na.action)

Arguments

- formula: a formula or a terms object or a data frame.
- data: a data frame used to find the objects in formula.
- na.action: function for handling missing values. Defaults to a na.action attribute of data, then a setting of the option na.action, or na.fail if that is not set.

Details
If formula is a data frame and data is missing, formula is used for data with the formula ~ .
Any character vectors in the formula are coerced to factors.
Value

A vector or list with one entry for each term in the formula giving the number(s) of replications for each level. If all levels are balanced (have the same number of replications) the result is a vector, otherwise it is a list with a component for each terms, as a vector, matrix or array as required.

A test for balance is `is.list(replications(formula,data)).`

Author(s)

The design was inspired by the S function of the same name described in Chambers et al (1992).

```

---

**reshape**

Reshape Grouped Data

Description

This function reshapes a data frame between 'wide' format with repeated measurements in separate columns of the same record and 'long' format with the repeated measurements in separate records.

Usage

```r
reshape(data, varying = NULL, v.names = NULL, timevar = "time",
idvar = "id", ids = 1:NROW(data),
times = seq_along(varying[[1]]),
drop = NULL, direction, new.row.names = NULL,
sep = ",",
split = if (sep == "") {
  list(regexp = "[A-Za-z][0-9]", include = TRUE)
} else {
  list(regexp = sep, include = FALSE, fixed = TRUE))
```
Arguments

data a data frame

varying names of sets of variables in the wide format that correspond to single variables in long format (‘time-varying’). This is canonically a list of vectors of variable names, but it can optionally be a matrix of names, or a single vector of names. In each case, the names can be replaced by indices which are interpreted as referring to names(data). See ‘Details’ for more details and options.

v.names names of variables in the long format that correspond to multiple variables in the wide format. See ‘Details’.

timevar the variable in long format that differentiates multiple records from the same group or individual. If more than one record matches, the first will be taken (with a warning).

idvar Names of one or more variables in long format that identify multiple records from the same group/individual. These variables may also be present in wide format.

ids the values to use for a newly created idvar variable in long format.

times the values to use for a newly created timevar variable in long format. See ‘Details’.

drop a vector of names of variables to drop before reshaping.

direction character string, either "wide" to reshape to wide format, or "long" to reshape to long format.

new.row.names character or NULL: a non-null value will be used for the row names of the result.

sep A character vector of length 1, indicating a separating character in the variable names in the wide format. This is used for guessing v.names and times arguments based on the names in varying. If sep == "", the split is just before the first numeral that follows an alphabetic character. This is also used to create variable names when reshaping to wide format.

split A list with three components, regexp, include, and (optionally) fixed. This allows an extended interface to variable name splitting. See ‘Details’.

Details

The arguments to this function are described in terms of longitudinal data, as that is the application motivating the functions. A ‘wide’ longitudinal dataset will have one record for each individual with some time-constant variables that occupy single columns and some time-varying variables that occupy a column for each time point. In ‘long’ format there will be multiple records for each individual, with some variables being constant across these records and others varying across the records. A ‘long’ format dataset also needs a ‘time’ variable identifying which time point each record comes from and an ‘id’ variable showing which records refer to the same person.

If the data frame resulted from a previous reshape then the operation can be reversed simply by reshape(a). The direction argument is optional and the other arguments are stored as attributes on the data frame.

If direction = "wide" and no varying or v.names arguments are supplied it is assumed that all variables except idvar and timevar are time-varying. They are all expanded into multiple variables in wide format.
If `direction = "long"` the varying argument can be a vector of column names (or a corresponding index). The function will attempt to guess the `v.names` and times from these names. The default is variable names like `x.1`, `x.2`, where `sep = "."` specifies to split at the dot and drop it from the name. To have alphabetic followed by numeric times use `sep = ""`.

Variable name splitting as described above is only attempted in the case where varying is an atomic vector, if it is a list or a matrix, `v.names` and times will generally need to be specified, although they will default to, respectively, the first variable name in each set, and sequential times.

Also, guessing is not attempted if `v.names` is given explicitly. Notice that the order of variables in varying is like `x.1.y.1.x.2.y.2`.

The split argument should not usually be necessary. The `split-regexp` component is passed to either `strsplit` or `regexpr`, where the latter is used if `split.include` is `TRUE`, in which case the splitting occurs after the first character of the matched string. In the `strsplit` case, the separator is not included in the result, and it is possible to specify fixed-string matching using `split$fixed`.

**Value**

The reshaped data frame with added attributes to simplify reshaping back to the original form.

**See Also**

`stack`, `aperm`, `relist` for reshaping the result of `unlist`.

**Examples**

```r
summary(Indometh)
wide <- reshape(Indometh, v.names = "conc", idvar = "Subject",
               timevar = "time", direction = "wide")
wide

reshape(wide, direction = "long")
reshape(wide, idvar = "Subject", varying = list(2:12),
        v.names = "conc", direction = "long")

## times need not be numeric
df <- data.frame(id = rep(1:4, rep(2,4)),
                 visit = I(rep(c("Before","After"), 4)),
                 x = rnorm(4), y = runif(4))
df
reshape(df, timevar = "visit", idvar = "id", direction = "wide")
## warns that y is really varying
reshape(df, timevar = "visit", idvar = "id", direction = "wide", v.names = "x")

## unbalanced 'long' data leads to NA fill in 'wide' form
df2 <- df[1:7, ]
df2
reshape(df2, timevar = "visit", idvar = "id", direction = "wide")

## Alternative regular expressions for guessing names
df3 <- data.frame(id = 1:4, age = c(40,50,60,55),
              dose1 = c(1,2,1,2),
              dose2 = c(2,1,2,1),
              dose3 = c(3,3,3,3))
reshape(df3, direction = "long", varying = 3:5, sep = "")

## an example that isn't longitudinal data
```
residuals

Description

residuals is a generic function which extracts model residuals from objects returned by modeling functions.

The abbreviated form resid is an alias for residuals. It is intended to encourage users to access object components through an accessor function rather than by directly referencing an object slot.

All object classes which are returned by model fitting functions should provide a residuals method. (Note that the method is for 'residuals' and not 'resid'.)

Methods can make use of naresid methods to compensate for the omission of missing values. The default, nls and smooth.spline methods do.

Usage

residuals(object, ...)
resid(object, ...)

Arguments

object an object for which the extraction of model residuals is meaningful.

... other arguments.

Value

Residuals extracted from the object object.

References

runmed

Running Medians – Robust Scatter Plot Smoothing

Description

Compute running medians of odd span. This is the ‘most robust’ scatter plot smoothing possible. For efficiency (and historical reason), you can use one of two different algorithms giving identical results.

Usage

runmed(x, k, endrule = c("median", "keep", "constant"), algorithm = NULL, print.level = 0)

Arguments

x numeric vector, the ‘dependent’ variable to be smoothed.

k integer width of median window; must be odd. Turlach had a default of k <- 1 + 2 * min((n-1)/% 2, ceiling(0.1*n)). Use k = 3 for ‘minimal’ robust smoothing eliminating isolated outliers.

drule character string indicating how the values at the beginning and the end (of the data) should be treated.

"keep" keeps the first and last k2 values at both ends, where k2 is the half-bandwidth k2 = k %/ 2, i.e., y[j] = x[j] for j ∈ {1,...,k2; n − k2 + 1,...,n};

"constant" copies median(y[1:k2]) to the first values and analogously for the last ones making the smoothed ends constant;

"median" the default, smooths the ends by using symmetrical medians of subsequently smaller bandwidth, but for the very first and last value where Tukey’s robust end-point rule is applied, see smoothEnds.

algorithm character string (partially matching “Turlach” or “Stuetzle”) or the default NULL, specifying which algorithm should be applied. The default choice depends on n = length(x) and k where “Turlach” will be used for larger problems.

print.level integer, indicating verboseness of algorithm; should rarely be changed by average users.

Details

Apart from the end values, the result y = runmed(x, k) simply has y[j] = median(x[j-k2:(j+k2)]) (k = 2*k2+1), computed very efficiently.

The two algorithms are internally entirely different:

"Turlach" is the Härdle–Steiger algorithm (see Ref.) as implemented by Berwin Turlach. A tree algorithm is used, ensuring performance O(n log k) where n = length(x) which is asymptotically optimal.

See Also

coefficients, fitted.values, glm, lm.
influence.measures for standardized (rstandard) and studentized (rstudent) residuals.
"Stuetzle" is the (older) Stuetzle–Friedman implementation which makes use of median updating when one observation enters and one leaves the smoothing window. While this performs as $O(n \times k)$ which is slower asymptotically, it is considerably faster for small $k$ or $n$.

Currently long vectors are only supported for algorithm = "Stuetzle".

Value

vector of smoothed values of the same length as x with an attribute k containing (the ‘oddified’) k.

Author(s)

Martin Maechler <maechler@stat.math.ethz.ch>, based on Fortran code from Werner Stuetzle and S-PLUS and C code from Berwin Turlach.

References

smoothEnds which implements Tukey’s end point rule and is called by default from runmed(*, endrule = "median"). smooth uses running medians of 3 for its compound smoothers.

Examples

require(graphics)
utils::example(nhtemp)
myNHT <- as.vector(nhtemp)
plot(myNHT, type = "b", ylim = c(48, 60), main = "Running Medians Example")
lines(runmed(myNHT, 7), col = "red")

## special: multiple y values for one x
plot(cars, main = "'cars' data and runmed(dist, 3)")
lines(cars, col = "light gray", type = "c")
with(cars, lines(speed, runmed(dist, k = 3), col = 2))

## nice quadratic with a few outliers
y <- ys <- (-20:20)^2
all(y == runmed(y, 1)) # 1-neighbourhood <==> interpolation
plot(y) # lines(y, lwd = .1, col = "light gray")
lines(lowess(seq(y), y, f = 0.3), col = "brown")
lines(runmed(y, 7), lwd = 2, col = "blue")
lines(runmed(y, 11), lwd = 2, col = "red")
rWishart

Random Wishart Distributed Matrices

Description

Generate \( n \) random matrices, distributed according to the Wishart distribution with parameters \( \Sigma \) and \( df \), \( W_p(\Sigma, m) \), \( m = df \), \( \Sigma = \Sigma \).

Usage

\texttt{rWishart(n, df, Sigma)}

Arguments

\begin{itemize}
  \item \texttt{n} integer sample size.
  \item \texttt{df} numeric parameter, “degrees of freedom”.
  \item \texttt{Sigma} positive definite \((p \times p)\) “scale” matrix, the matrix parameter of the distribution.
\end{itemize}

Details

If \( X_1, \ldots, X_m, X_i \in \mathbb{R}^p \) is a sample of \( m \) independent multivariate Gaussians with mean (vector) 0, and covariance matrix \( \Sigma \), the distribution of \( M = X'X \) is \( W_p(\Sigma, m) \).

Consequently, the expectation of \( M \) is

\[ E[M] = m \times \Sigma. \]

Further, if \( \Sigma \) is scalar \((p = 1)\), the Wishart distribution is a scaled chi-squared \((\chi^2)\) distribution with \( df \) degrees of freedom, \( W_1(\sigma^2, m) = \sigma^2 \chi^2_m \).

The component wise variance is

\[ \text{Var}(M_{ij}) = m(\Sigma_{ij}^2 + \Sigma_{ii}\Sigma_{jj}). \]

Value

a numeric array, say \( R \), of dimension \( p \times p \times n \), where each \( R[\cdot, \cdot, i] \) is a positive definite matrix, a realization of the Wishart distribution \( W_p(\Sigma, m) \), \( m = df \), \( \Sigma = \Sigma \).

Examples

```r
## Artificial
S <- toeplitz((1:10)/10)
s.set.seed(11)
R <- rWishart(1000, 20, S)
dim(R) # 10 10 1000
mR <- apply(R, 1:2, mean) # =~ E[ Wish(S, 20 ) ] = 20 * S
stopifnot(all.equal(mR, 20*S, tolerance = .000))

## See Details, the variance is
Va <- 20*(S^2 + tcrossprod(diag(S)))
vR <- apply(R, 1:2, var)
stopifnot(all.equal(vR, Va, tolerance = 1/16))
```

scatter.smooth

*Scatter Plot with Smooth Curve Fitted by Loess*

Description

Plot and add a smooth curve computed by `loess` to a scatter plot.

Usage

```r
scatter.smooth(x, y = NULL, span = 2/3, degree = 1,
family = c("symmetric", "gaussian"),
xlab = NULL, ylab = NULL,
ylim = range(y, pred$y, na.rm = TRUE),
evaluation = 50, ..., lpars = list())
```

loess.smooth(x, y, span = 2/3, degree = 1,
family = c("symmetric", "gaussian"), evaluation = 50, ...)

Arguments

- **x, y** the x and y arguments provide the x and y coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function `xy.coords` for details.
- **span** smoothness parameter for `loess`.
- **degree** degree of local polynomial used.
- **family** if "gaussian" fitting is by least-squares, and if family = "symmetric" a re-descending M estimator is used.
- **xlab** label for x axis.
**screeplot**

```

Details

loess.smooth is an auxiliary function which evaluates the loess smooth at evaluation equally spaced points covering the range of x.

Value

For scatter.smooth, none.

For loess.smooth, a list with two components, x (the grid of evaluation points) and y (the smoothed values at the grid points).

See Also

loess; smoothScatter for scatter plots with smoothed density color representation.

Examples

```
require(graphics)

with(cars, scatter.smooth(speed, dist))
## or with dotted thick smoothed line results :
with(cars, scatter.smooth(speed, dist, lpars =
  list(col = "red", lwd = 3, lty = 3)))
```

---

**screepplot**  

Screeplot

---

**Description**

screepplot.default plots the variances against the number of the principal component. This is also the plot method for classes "princomp" and "prcomp".

**Usage**

```

## Default S3 method:
screepplot(x,npcs = min(10, length(x$dev)),
  type = c("barplot", "lines"),
  main = deparse(substitute(x)), ...)
```
Arguments

- **x**: an object containing a `sdev` component, such as that returned by `princomp()` and `prcomp()`.
- **npcs**: the number of components to be plotted.
- **type**: the type of plot.
- **main, ...**: graphics parameters.

References

See Also

`princomp` and `prcomp`.

Examples

```r
require(graphics)

## The variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests, cor = TRUE)) # inappropriate
screeplot(pc.cr)

fit <- princomp(covmat = Harman74.cor)
screeplot(fit)
screeplot(fit,npcs = 24, type = "lines")
```

---

**sd**

*Standard Deviation*

Description

This function computes the standard deviation of the values in `x`. If `na.rm` is `TRUE` then missing values are removed before computation proceeds.

Usage

```r
sd(x, na.rm = FALSE)
```

Arguments

- **x**: a numeric vector or an `R` object which is coercible to one by `as.vector(x, "numeric")`.
- **na.rm**: logical. Should missing values be removed?

Details

Like `var` this uses denominator $n - 1$.

The standard deviation of a zero-length vector (after removal of NAs if `na.rm = TRUE`) is not defined and gives an error. The standard deviation of a length-one vector is NA.
See Also

`var` for its square, and `mad`, the most robust alternative.

Examples

```r
sd(1:2) ^ 2
```

---

**se.contrast**  
*Standard Errors for Contrasts in Model Terms*

**Description**

Returns the standard errors for one or more contrasts in an `aov` object.

**Usage**

```r
se.contrast(object, ...)  
## S3 method for class 'aov'
se.contrast(object, contrast.obj,  
            coef = contr.helmert(ncol(contrast))[1,],  
            data = NULL, ...)
```

**Arguments**

- **object**: A suitable fit, usually from `aov`.
- **contrast.obj**: The contrasts for which standard errors are requested. This can be specified via a list or via a matrix. A single contrast can be specified by a list of logical vectors giving the cells to be contrasted. Multiple contrasts should be specified by a matrix, each column of which is a numerical contrast vector (summing to zero).
- **coef**: used when `contrast.obj` is a list; it should be a vector of the same length as the list with zero sum. The default value is the first Helmert contrast, which contrasts the first and second cell means specified by the list.
- **data**: The data frame used to evaluate `contrast.obj`.
- **...**: further arguments passed to or from other methods.

**Details**

Contrasts are usually used to test if certain means are significantly different; it can be easier to use `se.contrast` than compute them directly from the coefficients.

In multistratum models, the contrasts can appear in more than one stratum, in which case the standard errors are computed in the lowest stratum and adjusted for efficiencies and comparisons between strata. (See the comments in the note in the help for `aov` about using orthogonal contrasts.) Such standard errors are often conservative.

Suitable matrices for use with `coef` can be found by calling `contrasts` and indexing the columns by a factor.

**Value**

A vector giving the standard errors for each contrast.
Examples

N <- c(0, 1, 0, 1, 1, 0, 0, 1, 0, 1, 0, 0, 1, 0, 1, 0, 0, 0, 0)
P <- c(0, 1, 0, 0, 0, 1, 1, 1, 0, 0, 0, 1, 0, 1, 1, 0, 0, 0, 0)
K <- c(0, 1, 0, 0, 1, 1, 0, 1, 0, 1, 0, 0, 1, 0, 1, 0, 0, 0, 0)
yield <- c(59.8, 58.5, 55.5, 55.0, 55.8, 60.8, 59.5, 55.8, 62.8, 59.5, 62.8, 59.5, 65.0, 55.0, 62.0, 48.8, 45.5, 44.2, 52.0, 51.5, 49.8, 48.8, 57.2, 59.0, 53.2, 56.0)
npk <- data.frame(block = gl(6, 4), N = factor(N), P = factor(P),
                 K = factor(K), yield = yield)
## Set suitable contrasts.
options(contrasts = c("contr.helmert", "contr.poly"))
npk.aov1 <- aov(yield ~ block + N + K, data = npk)
se.contrast(npk.aov1, list(N == "0", N == "1"), data = npk)
# or via a matrix
cont <- matrix(c(-1, 1, 2, 1, dimnames = list(NULL, "N")))
se.contrast(npk.aov1, cont[N, , drop = FALSE]/12, data = npk)

## test a multi-stratum model

npk.aov2 <- aov(yield ~ N + K + Error(block/(N + K)), data = npk)
se.contrast(npk.aov2, list(N == "0", N == "1"))

## an example looking at an interaction contrast
## Dataset from R.E. Kirk (1995)
## 'Experimental Design: procedures for the behavioural sciences'

score <- c(12, 8, 10, 6, 8, 10, 12, 8, 6, 10, 14, 9, 7, 9, 5, 11, 12,

fit2 <- lme(Yield ~ A + B*C, random = ~1 | Block, data = aovdat)
summary(fit2)$tTable # same estimates, similar (but smaller) se's.

### selfStart

**Construct Self-starting Nonlinear Models**

**Description**

Construct self-starting nonlinear models.

**Usage**

```r
selfStart(model, initial, parameters, template)
```

**Arguments**

- `model` a function object defining a nonlinear model or a nonlinear formula object of the form `~expression`.
- `initial` a function object, taking three arguments: `mCall`, `data`, and `lhs`, representing, respectively, a matched call to the function `model`, a data frame in which to interpret the variables in `mCall`, and the expression from the left-hand side of the model formula in the call to `nls`. This function should return initial values for the parameters in `model`.
- `parameters` a character vector specifying the terms on the right hand side of `model` for which initial estimates should be calculated. Passed as the `namevec` argument to the `deriv` function.
- `template` an optional prototype for the calling sequence of the returned object, passed as the `function.arg` argument to the `deriv` function. By default, a template is generated with the covariates in `model` coming first and the parameters in `model` coming last in the calling sequence.

**Details**

This function is generic; methods functions can be written to handle specific classes of objects.

**Value**

a function object of class "selfStart", for the `formula` method obtained by applying `deriv` to the right hand side of the `model` formula. An initial attribute (defined by the `initial` argument) is added to the function to calculate starting estimates for the parameters in the model automatically.

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

`nls`, `getInitial`. Each of the following are "selfStart" models (with examples) `SSasymp`, `SSasympOff`, `SSasympOrig`, `SSbiexp`, `SSfol`, `SSfpl`, `SSgompertz`, `SSlogis`, `SSmicmen`, `SSweibull"
Examples

```r
### self-starting logistic model

SSlogis <- selfStart(~ Asym/(1 + exp((xmid - x)/scal)),
  function(mCall, data, LHS)
  {
    xy <- sortedXYData(mCall["x"], LHS, data)
    if(nrow(xy) < 4) {
      stop("Too few distinct x values to fit a logistic")
    }
    z <- xy["y"]
    if (min(z) <= 0) { z <- z + 0.05 * max(z) } # avoid zeroes
    z <- z/(1.05 * max(z))  # scale to within unit height
    xy["z"] <- log(z/(1 - z))  # logit transformation
    aux <- coef(lm(x ~ z, xy))
    parameters(xy) <- list(xmid = aux[1], scal = aux[2])
    pars <- as.vector(coef(nls(y ~ 1/(1 + exp((xmid - x)/scal)),
      data = xy, algorithm = "plinear")))
    setNames(c(pars[3], pars[1], pars[2]),
      mCall[c("Asym", "xmid", "scal")])
  }, c("Asym", "xmid", "scal"))

# 'first.order.log.model' is a function object defining a first order
# compartment model
# 'first.order.log.initial' is a function object which calculates initial
# values for the parameters in 'first.order.log.model'

# self-starting first order compartment model
### Not run:
SSfol <- selfStart(first.order.log.model, first.order.log.initial)

### End(Not run)
```

Description

This is a convenience function that sets the names on an object and returns the object. It is most useful at the end of a function definition where one is creating the object to be returned and would prefer not to store it under a name just so the names can be assigned.

Usage

```r
setNames(object = nm, nm)
```
**Arguments**

- `object`: an object for which a `names` attribute will be meaningful
- `nm`: a character vector of names to assign to the object

**Value**

An object of the same sort as `object` with the new names assigned.

**Author(s)**

Douglas M. Bates and Saikat DebRoy

**See Also**

`unname` for removing names.

**Examples**

```r
setNames(1:3, c("foo", "bar", "baz") )
# this is just a short form of
tmp <- 1:3
names(tmp) <- c("foo", "bar", "baz")
tmp

## special case of character vector, using default
setNames(nm = c("First", "2nd"))
```

---

**shapiro.test**

**Shapiro-Wilk Normality Test**

**Description**

Performs the Shapiro-Wilk test of normality.

**Usage**

`shapiro.test(x)`

**Arguments**

- `x`: a numeric vector of data values. Missing values are allowed, but the number of non-missing values must be between 3 and 5000.

**Value**

A list with class "htest" containing the following components:

- `statistic`: the value of the Shapiro-Wilk statistic.
- `p.value`: an approximate p-value for the test. This is said in Royston (1995) to be adequate for `p.value < 0.1`.
- `method`: the character string "Shapiro-Wilk normality test".
- `data.name`: a character string giving the name(s) of the data.
The algorithm used is a C translation of the Fortran code described in Royston (1995) and found at http://lib.stat.cmu.edu/apstat/R94. The calculation of the p value is exact for \( n = 3 \), otherwise approximations are used, separately for \( 4 \leq n \leq 11 \) and \( n \geq 12 \).

References

See Also

`qqnorm` for producing a normal quantile-quantile plot.

Examples

```r
shapiro.test(rnorm(100, mean = 5, sd = 3))
shapiro.test(runif(100, min = 2, max = 4))
```

Description

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon Signed Rank statistic obtained from a sample with size \( n \).

Usage

```r
designrank(x, n, log = FALSE)
pdesignrank(q, n, lower.tail = TRUE, log.p = FALSE)
qdesignrank(p, n, lower.tail = TRUE, log.p = FALSE)
rsdesignrank(nn, n)
```

Arguments

- `x, q` vector of quantiles.
- `p` vector of probabilities.
- `nn` number of observations. If `length(nn) > 1`, the length is taken to be the number required.
- `n` number(s) of observations in the sample(s). A positive integer, or a vector of such integers.
- `log, log.p` logical; if TRUE, probabilities p are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).
**Details**

This distribution is obtained as follows. Let \( x \) be a sample of size \( n \) from a continuous distribution symmetric about the origin. Then the Wilcoxon signed rank statistic is the sum of the ranks of the absolute values \( x[i] \) for which \( x[i] \) is positive. This statistic takes values between 0 and \( n(n+1)/2 \), and its mean and variance are \( n(n+1)/4 \) and \( n(n+1)(2n+1)/24 \), respectively.

If either of the first two arguments is a vector, the recycling rule is used to do the calculations for all combinations of the two up to the length of the longer vector.

**Value**

`dsignrank` gives the density, `psignrank` gives the distribution function, `qsignrank` gives the quantile function, and `rsignrank` generates random deviates.

The length of the result is determined by `n` for `rsignrank`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Author(s)**

Kurt Hornik; efficiency improvement by Ivo Ugrina.

**See Also**

`wilcox.test` to calculate the statistic from data, find p values and so on.

Distributions for standard distributions, including `dwilcox` for the distribution of two-sample Wilcoxon rank sum statistic.

**Examples**

```r
require(graphics)
par(mfrow = c(2,2))
for(n in c(4:5,10,40)) {
  x <- seq(0, n*(n+1)/2, length = 501)
  plot(x, dsignrank(x, n = n), type = "l",
       main = paste0("dsignrank(x, n = ", n, ", "))
    }
```

---

**simulate**

*Simulate Responses*

**Description**

Simulate one or more responses from the distribution corresponding to a fitted model object.

**Usage**

```r
simulate(object, nsim = 1, seed = NULL, ...)
```
simulate

**Arguments**

- `object`: an object representing a fitted model.
- `nsim`: number of response vectors to simulate. Defaults to 1.
- `seed`: an object specifying if and how the random number generator should be initialized ("seeded").
  
  For the "lm" method, either NULL or an integer that will be used in a call to `set.seed` before simulating the response vectors. If set, the value is saved as the "seed" attribute of the returned value. The default, NULL will not change the random generator state, and return `.Random.seed` as the "seed" attribute, see 'Value'.

- `...`: additional optional arguments.

**Details**

This is a generic function. Consult the individual modeling functions for details on how to use this function.

Package `stats` has a method for "lm" objects which is used for `lm` and `glm` fits. There is a method for fits from `glm.nb` in package `MASS`, and hence the case of negative binomial families is not covered by the "lm" method.

The methods for linear models fitted by `lm` or `glm(family = "gaussian")` assume that any weights which have been supplied are inversely proportional to the error variance. For other GLMs the (optional) `simulate` component of the `family` object is used—there is no appropriate simulation method for ‘quasi’ models as they are specified only up to two moments.

For binomial and Poisson GLMs the dispersion is fixed at one. Integer prior weights $w_i$ can be interpreted as meaning that observation $i$ is an average of $w_i$ observations, which is natural for binomials specified as proportions but less so for a Poisson, for which prior weights are ignored with a warning.

For a gamma GLM the shape parameter is estimated by maximum likelihood (using function `gamma.shape` in package `MASS`). The interpretation of weights is as multipliers to a basic shape parameter, since dispersion is inversely proportional to shape.

For an inverse gaussian GLM the model assumed is $IG(\mu_i, \lambda w_i)$ (see [http://en.wikipedia.org/wiki/Inverse_Gaussian_distribution](http://en.wikipedia.org/wiki/Inverse_Gaussian_distribution)) where $\lambda$ is estimated by the inverse of the dispersion estimate for the fit. The variance is $\mu_i^3/(\lambda w_i)$ and hence inversely proportional to the prior weights. The simulation is done by function `rinvgauss` from the `SuppDists` package, which must be installed.

**Value**

Typically, a list of length `nsim` of simulated responses. Where appropriate the result can be a data frame (which is a special type of list).

For the "lm" method, the result is a data frame with an attribute "seed". If argument `seed` is `NULL`, the attribute is the value of `.Random.seed` before the simulation was started; otherwise it is the value of the argument with a "kind" attribute with value `as.list(RNGkind())`.

**See Also**

- `RNG` about random number generation in R,
- `fitted.values` and `residuals` for related methods;
- `glm, lm` for model fitting.

There are further examples in the 'simulate.R' tests file in the sources for package `stats`. 

Examples

x <- 1:5
mod1 <- lm(c(1:3, 7, 6) ~ x)
S1 <- simulate(mod1, nsim = 4)
## repeat the simulation:
.Random.seed <- attr(S1, "seed")
identical(S1, simulate(mod1, nsim = 4))

S2 <- simulate(mod1, nsim = 200, seed = 101)
rowMeans(S2) # should be about the same as fitted(mod1)

## repeat identically:
(sseed <- attr(S2, "seed")) # seed; RNGkind as attribute
stopifnot(identical(S2, simulate(mod1, nsim = 200, seed = sseed)))

## To be sure about the proper RNGkind, e.g., after
RNGversion("2.7.0")
## first set the RNG kind, then simulate
do.call(RNGkind, attr(sseed, "kind"))
identical(S2, simulate(mod1, nsim = 200, seed = sseed))

## Binomial GLM examples
yb1 <- matrix(c(4, 4, 5, 7, 8, 6, 6, 5, 3, 2), ncol = 2)
modb1 <- glm(yb1 ~ x, family = binomial)
S3 <- simulate(modb1, nsim = 4)
# each column of S3 is a two-column matrix.
x2 <- sort(runif(100))
yb2 <- rbinom(100, prob = plogis(2*(x2-1)), size = 1)
yb2 <- factor(1 + yb2, labels = c("failure", "success"))
modb2 <- glm(yb2 ~ x2, family = binomial)
S4 <- simulate(modb2, nsim = 4)
# each column of S4 is a factor

smooth Tukey's (Running Median) Smoothing

Description

Tukey’s smoothers, 3RS3R, 3RSS, 3R, etc.

Usage

smooth(x, kind = c("3RS3R", "3RSS", "3RSR", "3R", "3", "S"),
       twiceit = FALSE, endrule = "Tukey", do.ends = FALSE)

Arguments

  x        a vector or time series

  kind     a character string indicating the kind of smoother required; defaults to "3RS3R".
smooth

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>twiceit</code></td>
<td>logical, indicating if the result should be ‘twiced’. Twicing a smoother $S(y)$ means $S(y) + S(y - S(y))$, i.e., adding smoothed residuals to the smoothed values. This decreases bias (increasing variance).</td>
</tr>
<tr>
<td><code>endrule</code></td>
<td>a character string indicating the rule for smoothing at the boundary. Either &quot;Tukey&quot; (default) or &quot;copy&quot;.</td>
</tr>
<tr>
<td><code>do.ends</code></td>
<td>logical, indicating if the 3-splitting of ties should also happen at the boundaries (ends). This is only used for kind = &quot;S&quot;.</td>
</tr>
</tbody>
</table>

Details

3 is Tukey’s short notation for running median of length 3.
3R stands for Repeated 3 until convergence, and
S for Splitting of horizontal stretches of length 2 or 3.
Hence, 3R3R is a concatenation of 3R, S and 3R, 3RSS similarly, whereas 3R3R means first 3R and then (S and 3) Repeated until convergence – which can be bad.

Value

An object of class "tukeysmooth" (which has print and summary methods) and is a vector or time series containing the smoothed values with additional attributes.

Note

S and S-PLUS use a different (somewhat better) Tukey smoother in smooth(*). Note that there are other smoothing methods which provide rather better results. These were designed for hand calculations and may be used mainly for didactical purposes.
Since R version 1.2, smooth does really implement Tukey’s end-point rule correctly (see argument endrule).
kind = "3RSS" has been the default till R-1.1, but it can have very bad properties, see the examples.
Note that repeated application of smooth(*) does smooth more, for the "3RS*" kinds.

require(graphics)

## see also demo(smooth)!
x1 <- c(4, 1, 3, 6, 6, 4, 1, 6, 2, 4, 2) # very artificial
(x3R <- smooth(x1, "3R")) # 2 iterations of "3"
smooth(x3R, kind = "S")

sm.3RS <- function(x, ...) 
smooth(smooth(x, "3R", ...), "S", ...)

y <- c(1, 1, 19:1)
```
smooth.spline

Description

Fits a cubic smoothing spline to the supplied data.

Usage

\[
\text{smooth.spline}(x, y = \text{NULL}, w = \text{NULL}, \text{df} = \text{NULL}, \text{spar} = \text{NULL}, \text{cv} = \text{FALSE}, \\
\text{all.knots} = \text{FALSE}, \text{n.knots} = \text{.nknots.smooth}, \\
\text{keep.data} = \text{TRUE}, \text{df.offset} = 0, \text{penalty} = 1, \\
\text{control.spar} = \text{list()}, \text{tol} = 1e^{-6} \times \text{IQR}(x))
\]

Arguments

- \(x\) a vector giving the values of the predictor variable, or a list or a two-column matrix specifying \(x\) and \(y\).
- \(y\) responses. If \(y\) is missing or \(\text{NULL}\), the responses are assumed to be specified by \(x\), with \(x\) the index vector.
- \(w\) optional vector of weights of the same length as \(x\); defaults to all 1.
- \(\text{df}\) the desired equivalent number of degrees of freedom (trace of the smoother matrix).
- \(\text{spar}\) smoothing parameter, typically (but not necessarily) in \((0, 1]\). The coefficient \(\lambda\) of the integral of the squared second derivative in the fit (penalized log likelihood) criterion is a monotone function of \(\text{spar}\), see the details below.
- \(\text{cv}\) ordinary (\(\text{TRUE}\)) or ‘generalized’ cross-validation (GCV) when \(\text{FALSE}\); setting it to \(\text{NA}\) skips the evaluation of leverages and any score.
- \(\text{all.knots}\) if \(\text{TRUE}\), all distinct points in \(x\) are used as knots. If \(\text{FALSE}\) (default), a subset of \(x[i]\) is used, specifically \(x[j]\) where the \(\text{n.knots}\) indices are evenly spaced in \(1:n\), see also the next argument \(\text{n.knots}\).
n knots

tight integer or function giving the number of knots to use when
all knots = FALSE. If a function (as by default), the number of knots
is n knots(nx). By default for \( n_x > 49 \) this is less than \( n_x \), the number of
unique x values, see the Note.

keep.data

logical specifying if the input data should be kept in the result. If TRUE (as per
default), fitted values and residuals are available from the result.

df.offset

allows the degrees of freedom to be increased by df.offset in the GCV crite-

ory.

penalty

the coefficient of the penalty for degrees of freedom in the GCV criterion.

control.spar

optional list with named components controlling the root finding when the
smoothing parameter spar is computed, i.e., missing or NULL, see below.

Note that this is partly experimental and may change with general spar compu-
tation improvements!

low: lower bound for spar; defaults to -1.5 (used to implicitly default to 0 in R
versions earlier than 1.4).

high: upper bound for spar; defaults to +1.5.

tol: the absolute precision (tolerance) used; defaults to 1e-4 (formerly 1e-3).

eps: the relative precision used; defaults to 2e-8 (formerly 0.00244).
trace: logical indicating if iterations should be traced.

maxit: integer giving the maximal number of iterations; defaults to 500.

Note that spar is only searched for in the interval [low, high].

tol a tolerance for same-ness or uniqueness of the x values. The values are binned
into bins of size tol and values which fall into the same bin are regarded as the
same. Must be strictly positive (and finite).

details

Neither x nor y are allowed to containing missing or infinite values.

The x vector should contain at least four distinct values. ‘Distinct’ here is controlled by tol: values
which are regarded as the same are replaced by the first of their values and the corresponding
y and w are pooled accordingly.

The computational \( \lambda \) used (as a function of \( s = spar \)) is \( \lambda = r * 256^{3s-1} \) where \( r =
tr(X'WX)/tr(\Sigma), \Sigma \) is the matrix given by \( \Sigma_{ij} = \int B_i''(t)B_j''(t)dt \), X is given by \( X_{ij} = B_j(x_i) \),
W is the diagonal matrix of weights (scaled such that its trace is \( n \), the original number of observa-
tions) and \( B_k(.) \) is the k-th B-spline.

Note that with these definitions, \( f_i = f(x_i) \), and the B-spline basis representation \( f = Xc \) (i.e., c
is the vector of spline coefficients), the penalized log likelihood is \( L = (y - f)'W(y - f) + \lambda e'\Sigma e \),
and hence \( c \) is the solution of the (ridge regression) \( (X'WX + \lambda \Sigma)c = X'Wy \).

If spar is missing or NULL, the value of df is used to determine the degree of smoothing. If both
are missing, leave-one-out cross-validation (ordinary or ‘generalized’ as determined by cv) is used
to determine \( \lambda \). Note that from the above relation,

spar is \( s = s_0 + 0.0601 \times \log \lambda \), which is intentionally different from the S-PLUS implementation
of smooth.spline (where spar is proportional to \( \lambda \)). In \( \Lambda \)'s (\( \log \lambda \)) scale, it makes more sense to
vary spar linearly.

Note however that currently the results may become very unreliable for spar values smaller than
about -1 or -2. The same may happen for values larger than 2 or so. Don’t think of setting spar or
the controls low and high outside such a safe range, unless you know what you are doing!
The 'generalized' cross-validation method will work correctly when there are duplicated points in \( x \). However, it is ambiguous what leave-one-out cross-validation means with duplicated points, and the internal code uses an approximation that involves leaving out groups of duplicated points. \( cv = \text{TRUE} \) is best avoided in that case.

**Value**

An object of class "smooth.spline" with components

- \( x \) the distinct \( x \) values in increasing order, see the 'Details' above.
- \( y \) the fitted values corresponding to \( x \).
- \( w \) the weights used at the unique values of \( x \).
- \( yin \) the \( y \) values used at the unique \( y \) values.
- \( data \) only if \( \text{keep.data} = \text{TRUE} \): itself a list with components \( x, y \) and \( w \) of the same length. These are the original \( (x_i, y_i, w_i), i = 1, \ldots, n \), values where \( data \times x \) may have repeated values and hence be longer than the above \( x \) component; see details.
- \( lev \) (when \( cv \) was not \( \text{NA} \)) leverages, the diagonal values of the smoother matrix.
- \( cv\text{-crit} \) cross-validation score, 'generalized' or true, depending on \( cv \).
- \( \text{pen.crit} \) penalized criterion
- \( \text{crit} \) the criterion value minimized in the underlying \texttt{Fortran} routine 'sslvrg'.
- \( \text{df} \) equivalent degrees of freedom used. Note that (currently) this value may become quite imprecise when the true \( \text{df} \) is between 1 and 2.
- \( \text{spar} \) the value of \( \text{spar} \) computed or given.
- \( \text{lambda} \) the value of \( \lambda \) corresponding to \( \text{spar} \), see the details above.
- \( \text{iparms} \) named integer(3) vector where ..$\text{iparms}['\text{iter}'] \) gives number of \( \text{spar} \) computing iterations used.
- \( \text{fit} \) list for use by \texttt{predict.smooth.spline}, with components
  - \( \text{knot} \) the knot sequence (including the repeated boundary knots).
  - \( \text{nk} \) number of coefficients or number of 'proper' knots plus 2.
  - \( \text{coef} \) coefficients for the spline basis used.
- \( \text{min}, \text{range} \): numbers giving the corresponding quantities of \( x \).

**Note**

The number of unique \( x \) values, \( nx = n_x \), are determined by the \( \text{tol} \) argument, equivalently to

\[
  nx \leftarrow \text{length}(x) - \text{sum}(\text{duplicated}(\text{round}((x - \text{mean}(x)) / \text{tol})))
\]

The default \( \text{all.knots} = \text{FALSE} \) and \( \text{n.knots} = .\text{n.knots}.\text{smoothl} \), entails using only \( O(n_x^{0.2}) \) knots instead of \( n_x \) for \( n_x > 49 \). This cuts speed and memory requirements, but not drastically anymore since \texttt{R} version 1.5.1 where it is only \( O(n_k) + O(n) \) where \( n_k \) is the number of knots.

In this case where not all unique \( x \) values are used as knots, the result is not a smoothing spline in the strict sense, but very close unless a small smoothing parameter (or large \( \text{df} \)) is used.

**Author(s)**

\texttt{R} implementation by B. D. Ripley and Martin Maechler (\texttt{spar/lambda}, etc).
smooth.spline

Source

This function is based on code in the GAMFIT Fortran program by T. Hastie and R. Tibshirani ([http://lib.stat.cmu.edu/general/](http://lib.stat.cmu.edu/general/)), which makes use of spline code by Finbarr O’Sullivan. Its design parallels the smooth.spline function of Chambers & Hastie (1992).

```
## smoothEnds

### Description

Smooth end points of a vector \( y \) using subsequently smaller medians and Tukey's end point rule at the very end. (of odd span).

### Usage

\[
m\text{smoothEnds}(y, k = 3)
\]

### Arguments

- **y**: dependent variable to be smoothed (vector).
- **k**: width of largest median window; must be odd.

### Details

\text{smoothEnds} \text{ is used to only do the 'end point smoothing', i.e., change at most the observations closer to the beginning/end than half the window } k. \text{ The first and last value are computed using } Tukey's end point rule, i.e., sm[1] = median(y[1], sm[2], 3*sm[2] - 2*sm[3]).

### Value

vector of smoothed values, the same length as \( y \).

---

**sortedXyData**

Create a sortedXyData Object

**Description**

This is a constructor function for the class of sortedXyData objects. These objects are mostly used in the initial function for a self-starting nonlinear regression model, which will be of the selfStart class.

**Usage**

`sortedXyData(x, y, data)`

**Arguments**

- `x` a numeric vector or an expression that will evaluate in `data` to a numeric vector
- `y` a numeric vector or an expression that will evaluate in `data` to a numeric vector
- `data` an optional data frame in which to evaluate expressions for `x` and `y`, if they are given as expressions

**Value**

A sortedXyData object. This is a data frame with exactly two numeric columns, named `x` and `y`. The rows are sorted so the `x` column is in increasing order. Duplicate `x` values are eliminated by averaging the corresponding `y` values.
*Spec.ar*

**Author(s)**
José Pinheiro and Douglas Bates

**See Also**

`selfStart`, `NLSstClosestX`, `NLSstLfAsymptote`, `NLSstRtAsymptote`

**Examples**

```r
DNase.2 <- DNase[ DNase$Run == "2", ]
sortedXyData( expression(log(conc)), expression(density), DNase.2 )
```

**Description**
Fits an AR model to `x` (or uses the existing fit) and computes (and by default plots) the spectral density of the fitted model.

**Usage**

```r
spec.ar(x, n.freq, order = NULL, plot = TRUE, na.action = na.fail, method = "yule-walker", ...)```

**Arguments**

- `x` A univariate (not yet: or multivariate) time series or the result of a fit by `ar`.
- `n.freq` The number of points at which to plot.
- `order` The order of the AR model to be fitted. If omitted, the order is chosen by AIC.
- `plot` Plot the periodogram?
- `na.action` NA action function.
- `method` method for `ar` fit.
- `...` Graphical arguments passed to `plot.spec`.

**Value**
An object of class "spec". The result is returned invisibly if `plot` is true.

**Warning**
Some authors, for example Thomson (1990), warn strongly that AR spectra can be misleading.

**Note**
The multivariate case is not yet implemented.

spec.pgram

Estimate Spectral Density of a Time Series by a Smoothed Periodogram

Description

spec.pgram calculates the periodogram using a fast Fourier transform, and optionally smooths the result with a series of modified Daniell smoothers (moving averages giving half weight to the end values).

Usage

spec.pgram(x, spans = NULL, kernel, taper = 0.1,
           pad = 0, fast = TRUE, demean = FALSE, detrend = TRUE,
           plot = TRUE, na.action = na.fail, ...)

Arguments

x univariate or multivariate time series.

spans vector of odd integers giving the widths of modified Daniell smoothers to be used to smooth the periodogram.

kernel alternatively, a kernel smoother of class "tskernel".

taper specifies the proportion of data to taper. A split cosine bell taper is applied to this proportion of the data at the beginning and end of the series.

pad proportion of data to pad. Zeros are added to the end of the series to increase its length by the proportion pad.
spec.pgram

fast logical; if TRUE, pad the series to a highly composite length.
demean logical. If TRUE, subtract the mean of the series.
detrend logical. If TRUE, remove a linear trend from the series. This will also remove the mean.
plot plot the periodogram?
na.action NA action function.
...

graphical arguments passed to plot.spec.

Details

The raw periodogram is not a consistent estimator of the spectral density, but adjacent values are asymptotically independent. Hence a consistent estimator can be derived by smoothing the raw periodogram, assuming that the spectral density is smooth.

The series will be automatically padded with zeros until the series length is a highly composite number in order to help the Fast Fourier Transform. This is controlled by the fast and not the pad argument.

The periodogram at zero is in theory zero as the mean of the series is removed (but this may be affected by tapering): it is replaced by an interpolation of adjacent values during smoothing, and no value is returned for that frequency.

Value

A list object of class "spec" (see spectrum) with the following additional components:

kernel The kernel argument, or the kernel constructed from spans.
df The distribution of the spectral density estimate can be approximated by a (scaled) chi square distribution with df degrees of freedom.
bandwidth The equivalent bandwidth of the kernel smoother as defined by Bloomfield (1976, page 201).
taper The value of the taper argument.
pad The value of the pad argument.
detrend The value of the detrend argument.
demean The value of the demean argument.

The result is returned invisibly if plot is true.

**spec.taper**  
*Taper a Time Series by a Cosine Bell*

Description

Apply a cosine-bell taper to a time series.

Usage

```
spec.taper(x, p = 0.1)
```

Arguments

- **x**  
  A univariate or multivariate time series
- **p**  
  The proportion to be tapered at each end of the series, either a scalar (giving the proportion for all series) or a vector of the length of the number of series (giving the proportion for each series).

Details

The cosine-bell taper is applied to the first and last $p[i]$ observations of time series $x[ , i]$. 
spectrum

Value
A new time series object.

See Also
spec.pgram, cgram

spectrum  Spectral Density Estimation

Description
The spectrum function estimates the spectral density of a time series.

Usage
spectrum(x, ..., method = c("pgram", "ar"))

Arguments
x  A univariate or multivariate time series.
method  String specifying the method used to estimate the spectral density. Allowed methods are "pgram" (the default) and "ar".
...  Further arguments to specific spec methods or plot.spec.

Details
spectrum is a wrapper function which calls the methods spec.pgram and spec.ar.
The spectrum here is defined with scaling 1/frequency(x), following S-PLUS. This makes the spectral density a density over the range \(-\text{frequency}(x)/2, +\text{frequency}(x)/2\], whereas a more common scaling is \(2\pi\) and range \((-0.5, 0.5]\) (e.g., Bloomfield) or 1 and range \((-\pi, \pi]\).

If available, a confidence interval will be plotted by plot.spec: this is asymmetric, and the width of the centre mark indicates the equivalent bandwidth.

Value
An object of class "spec", which is a list containing at least the following components:

freq  vector of frequencies at which the spectral density is estimated. (Possibly approximate Fourier frequencies.) The units are the reciprocal of cycles per unit time (and not per observation spacing): see 'Details' below.
spec  Vector (for univariate series) or matrix (for multivariate series) of estimates of the spectral density at frequencies corresponding to freq.
coh  NULL for univariate series. For multivariate time series, a matrix containing the squared coherency between different series. Column \(i + (j - 1) * (j - 2)/2\) of coh contains the squared coherency between columns \(i\) and \(j\) of \(x\), where \(i < j\).
phase  NULL for univariate series. For multivariate time series a matrix containing the cross-spectrum phase between different series. The format is the same as coh.
series  The name of the time series.
spectrum

snames For multivariate input, the names of the component series.
method The method used to calculate the spectrum.

The result is returned invisibly if plot is true.

Note

The default plot for objects of class "spec" is quite complex, including an error bar and default title,
subtitle and axis labels. The defaults can all be overridden by supplying the appropriate graphical
parameters.

splinefun

Interpolating Splines

Description

Perform cubic (or Hermite) spline interpolation of given data points, returning either a list of points obtained by the interpolation or a function performing the interpolation.

Usage

splinefun(x, y = NULL, method = c("fmm", "periodic", "natural", "monoH.FC", "hyman"), ties = mean)

spline(x, y = NULL, n = 3*length(x), method = "fmm", xmin = min(x), xmax = max(x), xout, ties = mean)

splinefunH(x, y, m)

Arguments

x, y vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see xy.coords.

y must be increasing or decreasing for method = "hyman".

m (for splinefunH()): vector of slopes $m_i$ at the points $(x_i, y_i)$; these together determine the Hermite "spline" which is piecewise cubic, (only) once differentiable continuously.

method specifies the type of spline to be used. Possible values are "fmm", "natural", "periodic", "monoH.FC" and "hyman".

n if xout is left unspecified, interpolation takes place at n equally spaced points spanning the interval $[\text{xmin, xmax}]$.

xmin, xmax left-hand and right-hand endpoint of the interpolation interval (when xout is unspecified).

xout an optional set of values specifying where interpolation is to take place.

ties Handling of tied x values. Either a function with a single vector argument returning a single number result or the string "ordered".

Details

The inputs can contain missing values which are deleted, so at least one complete $(x_i, y_i)$ pair is required. If method = "fmm", the spline used is that of Forsythe, Malcolm and Moler (an exact cubic is fitted through the four points at each end of the data, and this is used to determine the end conditions). Natural splines are used when method = "natural", and periodic splines when method = "periodic".

The method "monoH.FC" computes a monotone Hermite spline according to the method of Fritsch and Carlson. It does so by determining slopes such that the Hermite spline, determined by $(x_i, y_i, m_i)$, is monotone (increasing or decreasing) iff the data are.

Method "hyman" computes a monotone cubic spline using Hyman filtering of an method = "fmm" fit for strictly monotonic inputs. (Added in R 2.15.2.)
These interpolation splines can also be used for extrapolation, that is prediction at points outside the range of \( x \). Extrapolation makes little sense for `method = "fmm"`; for natural splines it is linear using the slope of the interpolating curve at the nearest data point.

**Value**

`spline` returns a list containing components \( x \) and \( y \) which give the ordinates where interpolation took place and the interpolated values.

`splinefun` returns a function with formal arguments \( x \) and `deriv`, the latter defaulting to zero. This function can be used to evaluate the interpolating cubic spline (`deriv = 0`), or its derivatives (`deriv = 1, 2, 3`) at the points \( x \), where the spline function interpolates the data points originally specified. It uses data stored in its environment when it was created, the details of which are subject to change.

**Warning**

The value returned by `splinefun` contains references to the code in the current version of \( \mathbb{R} \): it is not intended to be saved and loaded into a different \( \mathbb{R} \) session. This is safer in \( \mathbb{R} \geq 3.0.0 \).

**Author(s)**

R Core Team.

SSasymp

Self-Starting Nls Asymptotic Regression Model

Description

This selfStart model evaluates the asymptotic regression function and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Asym, R0, and lrc for a given set of data.

Usage

SSasymp(input, Asym, R0, lrc)

Arguments

- **input**: a numeric vector of values at which to evaluate the model.
- **Asym**: a numeric parameter representing the horizontal asymptote on the right side (very large values of input).
- **R0**: a numeric parameter representing the response when input is zero.
- **lrc**: a numeric parameter representing the natural logarithm of the rate constant.

Value

A numeric vector of the same length as input. It is the value of the expression Asym + (R0 - Asym) * exp(-exp(lrc) * input). If all of the arguments Asym, R0, and lrc are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.
SSasympOff

Self-Starting Nls Asymptotic Regression Model with an Offset

Description
This selfStart model evaluates an alternative parametrization of the asymptotic regression function and the gradient with respect to those parameters. It has an initial attribute that creates initial estimates of the parameters Asym, lrc, and c0.

Usage
SSasympOff(input, Asym, lrc, c0)

Arguments

- **input**: a numeric vector of values at which to evaluate the model.
- **Asym**: a numeric parameter representing the horizontal asymptote on the right side (very large values of input).
- **lrc**: a numeric parameter representing the natural logarithm of the rate constant.
- **c0**: a numeric parameter representing the input for which the response is zero.

Value

A numeric vector of the same length as input. It is the value of the expression \( \text{Asym} \times (1 - \exp(-\exp(\text{lrc}) \times (\text{input} - \text{c0}))) \). If all of the arguments Asym, lrc, and c0 are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

Author(s)
José Pinheiro and Douglas Bates
SSasympOrig

Self-Starting Nls Asymptotic Regression Model through the Origin

Description

This selfStart model evaluates the asymptotic regression function through the origin and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Asym and lrc for a given set of data.

Usage

SSasympOrig(input, Asym, lrc)

Arguments

input       a numeric vector of values at which to evaluate the model.
Asym        a numeric parameter representing the horizontal asymptote.
lrc         a numeric parameter representing the natural logarithm of the rate constant.

Value

a numeric vector of the same length as input. It is the value of the expression Asym*(1 - exp(-exp(lrc)*input)). If all of the arguments Asym and lrc are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

```

**SSbiexp**

Self-Starting Nls Biexponential model

Description

This selfStart model evaluates the biexponential model function and its gradient. It has an initial attribute that creates initial estimates of the parameters $A_1, \ln c_1, A_2$, and $\ln c_2$.

Usage

```r
SSbiexp(input, A1, lrc1, A2, lrc2)
```

Arguments

- `input`: a numeric vector of values at which to evaluate the model.
- `A1`: a numeric parameter representing the multiplier of the first exponential.
- `lrc1`: a numeric parameter representing the natural logarithm of the rate constant of the first exponential.
- `A2`: a numeric parameter representing the multiplier of the second exponential.
- `lrc2`: a numeric parameter representing the natural logarithm of the rate constant of the second exponential.

Value

a numeric vector of the same length as `input`. It is the value of the expression $A_1 \exp(-\exp(lrc1) \times \text{input}) + A_2 \exp(-\exp(lrc2) \times \text{input})$. If all of the arguments `A1`, `lrc1`, `A2`, and `lrc2` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

### SSD

**SSD Matrix and Estimated Variance Matrix in Multivariate Models**

**Description**

Functions to compute matrix of residual sums of squares and products, or the estimated variance matrix for multivariate linear models.

**Usage**

- For class `mlm`
  ```r
  SSD(object, ...)  
  ```
- For class `SSD` and `mlm`
  ```r
  estVar(object, ...)  
  ```

**Arguments**

- `object` object of class "mlm", or "SSD" in the case of `estVar`.
- `...` Unused
Value

SSD() returns a list of class "SSD" containing the following components

SSD The residual sums of squares and products matrix
df Degrees of freedom
call Copied from object

estVar returns a matrix with the estimated variances and covariances.

SSf0l

Self-Starting Nls First-order Compartment Model

Description

This selfStart model evaluates the first-order compartment function and its gradient. It has an initial attribute that creates initial estimates of the parameters 1Ke, 1Ka, and 1Cl.

Usage

SSf0l(Dose, input, 1Ke, 1Ka, 1Cl)
Arguments

Dose  a numeric value representing the initial dose.
input a numeric vector at which to evaluate the model.
1Ke  a numeric parameter representing the natural logarithm of the elimination rate constant.
1Ka  a numeric parameter representing the natural logarithm of the absorption rate constant.
1Cl  a numeric parameter representing the natural logarithm of the clearance.

Value

a numeric vector of the same length as input, which is the value of the expression

\[
\text{Dose} \times \exp(\text{1Ke}+\text{1Ka}-\text{1Cl}) \times \left(\exp(-\exp(\text{1Ke})\times\text{input}) - \exp(-\exp(\text{1Ka})\times\text{input})\right) / \left(\exp(\text{1Ka}) - \exp(\text{1Ke})\right)
\]

If all of the arguments 1Ke, 1Ka, and 1Cl are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

SSfpl

Self-Starting Nls Four-Parameter Logistic Model

Description

This selfStart model evaluates the four-parameter logistic function and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters A, B, xmid, and scal for a given set of data.

Usage

SSfpl(input, A, B, xmid, scal)
**SSgompertz**

**Self-Starting Nls Gompertz Growth Model**

**Description**

This selfStart model evaluates the Gompertz growth model and its gradient. It has an initial attribute that creates initial estimates of the parameters Asym, b2, and b3.

**Usage**

`SSgompertz(x, Asym, b2, b3)`

**Arguments**

- `input`: a numeric vector of values at which to evaluate the model.
- `Asym`: a numeric parameter representing the horizontal asymptote on the left side (very small values of `input`).
- `b`: a numeric parameter representing the horizontal asymptote on the right side (very large values of `input`).
- `xmid`: a numeric parameter representing the `input` value at the inflection point of the curve. The value of `SSfp1` will be midway between `A` and `B` at `xmid`.
- `scal`: a numeric scale parameter on the `input` axis.

**Value**

A numeric vector of the same length as `input`. It is the value of the expression \( A + (B - A)/([1 + \exp((xmid - input)/scal))] \). If all of the arguments `A`, `B`, `xmid`, and `scal` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSfp1(Chick.1$Time, 13, 368, 14, 6)  # response only
A <- 13; B <- 368; xmid <- 14; scal <- 6
SSfp1(Chick.1$Time, A, B, xmid, scal)  # response and gradient
print(getInitial(weight ~ SSfp1(Time, A, B, xmid, scal), data = Chick.1),
      digits = 5)
## Initial values are in fact the converged values
fm1 <- nls(weight ~ SSfp1(Time, A, B, xmid, scal), data = Chick.1)
summary(fm1)
```
**Arguments**

- `x` a numeric vector of values at which to evaluate the model.
- `Asym` a numeric parameter representing the asymptote.
- `b2` a numeric parameter related to the value of the function at \( x = 0 \)
- `b3` a numeric parameter related to the scale the \( x \) axis.

**Value**

a numeric vector of the same length as `input`. It is the value of the expression \( \text{Asym} \times \exp(-b2+b3 \times x) \). If all of the arguments `Asym`, `b2`, and `b3` are names of objects the gradient matrix with respect to these names is attached as an attribute named `gradient`.

**SSlogis**

**Self-Starting Nls Logistic Model**

**Description**

This `selfStart` model evaluates the logistic function and its gradient. It has an initial attribute that creates initial estimates of the parameters `Asym`, `xmid`, and `scal`.

**Usage**

`SSlogis(input, Asym, xmid, scal)`

**Arguments**

- `input` a numeric vector of values at which to evaluate the model.
- `Asym` a numeric parameter representing the asymptote.
- `xmid` a numeric parameter representing the \( x \) value at the inflection point of the curve. The value of `SSlogis` will be `Asym/2` at `xmid`.
- `scal` a numeric scale parameter on the input axis.
Value

a numeric vector of the same length as input. It is the value of the expression \( \text{Asym}/(1 + \exp((\text{xmid} - \text{input})/\text{scal})) \). If all of the arguments \text{Asym}, \text{xmid}, and \text{scal} are names of objects the gradient matrix with respect to these names is attached as an attribute named \text{gradient}.

SSmicmen  Self-Starting Nls Michaelis-Menten Model

Description

This selfStart model evaluates the Michaelis-Menten model and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters \text{Vm} and \text{K}

Usage

SSmicmen(input, Vm, K)

Arguments

input  a numeric vector of values at which to evaluate the model.
Vm  a numeric parameter representing the maximum value of the response.
K  a numeric parameter representing the input value at which half the maximum response is attained. In the field of enzyme kinetics this is called the Michaelis parameter.

Value

a numeric vector of the same length as input. It is the value of the expression \( \text{Vm} \times \text{input}/(\text{K} + \text{input}) \). If both the arguments \text{Vm} and \text{K} are names of objects, the gradient matrix with respect to these names is attached as an attribute named \text{gradient}.
SSweibull

Self-Starting Nls Weibull Growth Curve Model

Description

This `selfStart` model evaluates the Weibull model for growth curve data and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters `Asym`, `Drop`, `lrc`, and `pwr` for a given set of data.

Usage

`SSweibull(x, Asym, Drop, lrc, pwr)`

Arguments

- `x` a numeric vector of values at which to evaluate the model.
- `Asym` a numeric parameter representing the horizontal asymptote on the right side (very small values of `x`).
- `Drop` a numeric parameter representing the change from `Asym` to the y intercept.
- `lrc` a numeric parameter representing the natural logarithm of the rate constant.
- `pwr` a numeric parameter representing the power to which `x` is raised.

Details

This model is a generalization of the `SSasym` model in that it reduces to `SSasym` when `pwr` is unity.

Examples

```r
PurTrt <- Puromycin[ Puromycin$state == "treated", ]
SSmicmen(PurTrt$conc, 200, 0.05) # response only
Vm <- 200; K <- 0.05
SSmicmen(PurTrt$conc, Vm, K)   # response and gradient
print(getInitial(rate ~ SSmicmen(conc, Vm, K), data = PurTrt), digits = 3)
## Initial values are in fact the converged values
fm1 <- nls(rate ~ SSmicmen(conc, Vm, K), data = PurTrt)
summary(fm1)
## Alternative call using the subset argument
fm2 <- nls(rate ~ SSmicmen(conc, Vm, K), data = Puromycin,
         subset = state == "treated")
summary(fm2)
```
**Value**

A numeric vector of the same length as `x`. It is the value of the expression `Asym*Drop*exp(-exp(lrc)*x^pwr)`. If all of the arguments `Asym`, `Drop`, `lrc`, and `pwr` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

**See Also**

`nls`, `selfStart`, `SSasymp`

**Examples**

```r
Chick.6 <- subset(ChickWeight, (Chick == 6) & (Time > 0))
SSWeibull(Chick.6$Time, 160, 115, -5.5, 2.5)  # response only
Asym <- 160; Drop <- 115; lrc <- -5.5; pwr <- 2.5
SSWeibull(Chick.6$Time, Asym, Drop, lrc, pwr)  # response and gradient
getInitial(weight ~ SSWeibull(Time, Asym, Drop, lrc, pwr), data = Chick.6)
## Initial values are in fact the converged values
fml <- nls(weight ~ SSWeibull(Time, Asym, Drop, lrc, pwr), data = Chick.6)
summary(fml)
```

---

**Description**

Extract and encode the times the first and last observations were taken. Provided only for compatibility with S version 2.

**Usage**

```r
start(x, ...)
end(x, ...)
```

**Arguments**

- `x` a univariate or multivariate time-series, or a vector or matrix.
- `...` extra arguments for future methods.

**Details**

These are generic functions, which will use the `tsp` attribute of `x` if it exists. Their default methods decode the start time from the original time units, so that for a monthly series 1995.5 is represented as `c(1995, 7)`. For a series of frequency `f`, time `n*i/f` is presented as `c(n, i+1)` (even for `i = 0` and `f = 1`).
Warning

The representation used by start and end has no meaning unless the frequency is supplied.

stat.anova  GLM Anova Statistics

Description

This is a utility function, used in lm and glm methods for anova(..., test != NULL) and should not be used by the average user.

Usage

stat.anova(table, test = c("Rao","LRT", "Chisq", "F", "Cp"),
           scale, df.scale, n)

Arguments

table  numeric matrix as results from anova.lm(..., test = NULL).
test   a character string, matching one of "Rao", "LRT", "Chisq", "F" or "Cp".
scale  a residual mean square or other scale estimate to be used as the denominator in an F test.
df.scale degrees of freedom corresponding to scale.
n number of observations.

Value

A matrix which is the original table, augmented by a column of test statistics, depending on the test argument.

References

See Also

anova.lm, anova.glm.

Examples

###-- Continued from '?glm':

print(ag <- anova(glm.D93))
stat.anova(ag$table, test = "Cp",
          scale = sum(resid(glm.D93, "pearson")^2)/4,
          df.scale = 4, n = 9)
Description

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as the next release.

Usage

```r
plclust(tree, hang = 0.1, unit = FALSE, level = FALSE, hmin = 0,
         square = TRUE, labels = NULL, plot. = TRUE,
         axes = TRUE, frame.plot = FALSE, ann = TRUE,
         main = "", sub = NULL, xlab = NULL, ylab = "Height")
```

Arguments

tree  an object of the type produced by `hclust`.

hang  The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.

unit  logical. If true, the splits are plotted at equally-spaced heights rather than at the height in the object.

labels  A character vector of labels for the leaves of the tree. By default the row names or row numbers of the original data are used. If `labels = FALSE` no labels at all are plotted.

axes, frame.plot, ann  logical flags as in `plot.default`.

main, sub, xlab, ylab  character strings for `title`. `sub` and `xlab` have a non-NULL default when there’s a `tree$call`.

...  Further graphical arguments. E.g., `cex` controls the size of the labels (if plotted) in the same way as `text`.

hmin  numeric. All heights less than `hmin` are regarded as being `hmin`: this can be used to suppress detail at the bottom of the tree.

level, square, plot.  unimplemented arguments for S-PLUS compatibility.

Details

`plclust` is a deprecated wrapper for the `plot` method for `hclust`, provided long ago for S-PLUS compatibility.

`Deprecated`
step

Choose a model by AIC in a Stepwise Algorithm

Description

Select a formula-based model by AIC.

Usage

step(object, scope, scale = 0,
    direction = c("both", "backward", "forward"),
    trace = 1, keep = NULL, steps = 1000, k = 2, ...)

Arguments

object an object representing a model of an appropriate class (mainly "lm" and "glm").
        This is used as the initial model in the stepwise search.

scope defines the range of models examined in the stepwise search. This should be
        either a single formula, or a list containing components upper and lower, both
        formulae. See the details for how to specify the formulae and how they are used.

scale used in the definition of the AIC statistic for selecting the models, currently only
        for lm, aov and glm models. The default value, 0, indicates the scale should be
        estimated: see extractAIC.

direction the mode of stepwise search, can be one of "both", "backward", or "forward",
        with a default of "both". If the scope argument is missing the default for
        direction is "backward".

trace if positive, information is printed during the running of step. Larger values may
        give more detailed information.

keep a filter function whose input is a fitted model object and the associated AIC
        statistic, and whose output is arbitrary. Typically keep will select a subset of the
        components of the object and return them. The default is not to keep anything.

steps the maximum number of steps to be considered. The default is 1000 (essentially
        as many as required). It is typically used to stop the process early.

k the multiple of the number of degrees of freedom used for the penalty. Only
        k = 2 gives the genuine AIC: k = 1og(n) is sometimes referred to as BIC or
        SBC.

... any additional arguments to extractAIC.

Details

step uses add1 and drop1 repeatedly; it will work for any method for which they work, and that
        is determined by having a valid method for extractAIC. When the additive constant can be chosen
        so that AIC is equal to Mallows’ $C_p$, this is done and the tables are labelled appropriately.

The set of models searched is determined by the scope argument. The right-hand-side of its lower
        component is always included in the model, and right-hand-side of the model is included in the
        upper component. If scope is a single formula, it specifies the upper component, and the lower
        model is empty. If scope is missing, the initial model is used as the upper model.
Models specified by scope can be templates to update object as used by `update.formula`. So using `.` in a scope formula means ‘what is already there’, with `.^2` indicating all interactions of existing terms.

There is a potential problem in using `glm` fits with a variable scale, as in that case the deviance is not simply related to the maximized log-likelihood. The "glm" method for function `extractAIC` makes the appropriate adjustment for a `gaussian` family, but may need to be amended for other cases. (The `binomial` and `poisson` families have fixed `scale` by default and do not correspond to a particular maximum-likelihood problem for variable `scale`.)

**Value**

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log-likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).

**Warning**

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and R's default of `na.action = na.omit` is used. We suggest you remove the missing values first.

Calls to the function `nobs` are used to check that the number of observations involved in the fitting process remains unchanged.

**Note**

This function differs considerably from the function in S, which uses a number of approximations and does not in general compute the correct AIC.

This is a minimal implementation. Use `stepAIC` in package `MASS` for a wider range of object classes.

**Author(s)**

B. D. Ripley: `step` is a slightly simplified version of `stepAIC` in package `MASS` (Venables & Ripley, 2002 and earlier editions).

The idea of a `step` function follows that described in Hastie & Pregibon (1992); but the implementation in R is more general.

Step Functions - Creation and Class

Given the vectors \((x_1, \ldots, x_n)\) and \((y_0, y_1, \ldots, y_n)\) (one value more!), \(\text{stepfun}(x, y, \ldots)\) returns an interpolating 'step' function, say \(fn\). I.e., \(fn(t) = c_i\) (constant) for \(t \in (x_i, x_{i+1})\) and at the abscissa values, if (by default) \(\text{right} = \text{FALSE}\), \(fn(x_i) = y_i\) and for \(\text{right} = \text{TRUE}\), \(fn(x_i) = y_{i-1}\), for \(i = 1, \ldots, n\).

The value of the constant \(c_i\) above depends on the 'continuity' parameter \(f\). For the default, \(\text{right} = \text{FALSE}\), \(f = 0\), \(fn\) is a \textit{cadlag} function, i.e., continuous from the right, limits from the left, so that the function is piecewise constant on intervals that include their left endpoint. In general, \(c_i\) is interpolated in between the neighbouring \(y\) values, \(c_i = (1-f)y_i + f \cdot y_{i+1}\). Therefore, for non-0 values of \(f\), \(fn\) may no longer be a proper step function, since it can be discontinuous from both sides, unless \(\text{right} = \text{TRUE}\), \(f = 1\) which is left-continuous (i.e., constant pieces contain their right endpoint).

Usage

```r
stepfun(x, y, f = as.numeric(right), ties = "ordered",
        right = \text{FALSE})
```

```r
is.stepfun(x)
```

```
knotted(Fn, ...)
```

```r
as.stepfun(x, ...)
```

```r
## S3 method for class 'stepfun'
print(x, digits = getOption("digits") - 2, ...)
```

```r
## S3 method for class 'stepfun'
summary(object, ...)
```

Arguments

- **x**
  numeric vector giving the knots or jump locations of the step function for \(\text{stepfun}()\). For the other functions, \(x\) is as object below.

- **y**
  numeric vector one longer than \(x\), giving the heights of the function values between the \(x\) values.

- **f**
  a number between 0 and 1, indicating how interpolation outside the given \(x\) values should happen. See \texttt{approxfun}.
ties Handling of tied x values. Either a function or the string "ordered". See approxfun.

right logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.

fn, object an R object inheriting from "stepfun".

digits number of significant digits to use, see print.

... potentially further arguments (required by the generic).

Value

A function of class "stepfun", say fn.

There are methods available for summarizing ("summary(.)"), representing ("print(.)") and plotting ("plot(.)", see plot.stepfun) "stepfun" objects.

The environment of fn contains all the information needed;

"x", "y" the original arguments

"n" number of knots (x values)

"f" continuity parameter

"yleft", "yright" the function values outside the knots

"method" (always == "constant", from approxfun(.)).

The knots are also available via knots(fn).

Note

The objects of class "stepfun" are not intended to be used for permanent storage and may change structure between versions of R (and did at R 3.0.0). They can usually be re-created by

```
  eval(attr(old_obj, "call"), environment(old_obj))
```

since the data used is stored as part of the object’s environment.

Examples

```R
y0 <- c(1., 2., 4., 3.)
sfun0 <- stepfun(1:3, y0, f = 0)
sfun.2 <- stepfun(1:3, y0, f = 0.2)
sfun1 <- stepfun(1:3, y0, f = 1)
sfun1c <- stepfun(1:3, y0, right = TRUE) # hence f=1
sfun0
summary(sfun0)
```
stl

Seasonal Decomposition of Time Series by Loess

Description

Decompose a time series into seasonal, trend and irregular components using `loess`, acronym STL.

Usage

```r
stl(x, s.window, s.degree = 0,
    t.window = NULL, t.degree = 1,
    l.window = nextodd(period), l.degree = t.degree,
    s.jump = ceiling(s.window/10),
    t.jump = ceiling(t.window/10),
    l.jump = ceiling(l.window/10),
    robust = FALSE,
    inner = if(robust) 1 else 2,
    outer = if(robust) 15 else 0,
    na.action = na.fail)
```

Arguments

- **x**: univariate time series to be decomposed. This should be an object of class "ts" with a frequency greater than one.
- **s.window**: either the character string "periodic" or the span (in lags) of the loess window for seasonal extraction, which should be odd. This has no default.
- **s.degree**: degree of locally-fitted polynomial in seasonal extraction. Should be zero or one.
- **t.window**: the span (in lags) of the loess window for trend extraction, which should be odd. If NULL, the default, `nextodd(ceiling((1.5*period) / (1-(1.5/s.window))))`, is taken.
- **t.degree**: degree of locally-fitted polynomial in trend extraction. Should be zero or one.
- **l.window**: the span (in lags) of the loess window of the low-pass filter used for each subseries. Defaults to the smallest odd integer greater than or equal to `frequency(x)` which is recommended since it prevents competition between the trend and seasonal components. If not an odd integer its given value is increased to the next odd one.
stl

1. degree  
   degree of locally-fitted polynomial for the subseries low-pass filter. Must be 0 or 1.

s.jump, t.jump, l.jump  
   integers at least one to increase speed of the respective smoother. Linear interpolation happens between every \* jump value.

robust  
   logical indicating if robust fitting be used in the loess procedure.

inner  
   integer; the number of ‘inner’ (backfitting) iterations; usually very few (2) iterations suffice.

outer  
   integer; the number of ‘outer’ robustness iterations.

na.action  
   action on missing values.

Details

The seasonal component is found by loess smoothing the seasonal sub-series (the series of all January values, ...); if s.window = "periodic" smoothing is effectively replaced by taking the mean. The seasonal values are removed, and the remainder smoothed to find the trend. The overall level is removed from the seasonal component and added to the trend component. This process is iterated a few times. The remainder component is the residuals from the seasonal plus trend fit.

Several methods for the resulting class "stl" objects, see, plot.stl.

Value

stl returns an object of class "stl" with components

time.series  
   a multiple time series with columns seasonal, trend and remainder.

weights  
   the final robust weights (all one if fitting is not done robustly).

call  
   the matched call.

win  
   integer (length 3 vector) with the spans used for the "s", "t", and "l" smoothers.

deg  
   integer (length 3) vector with the polynomial degrees for these smoothers.

jump  
   integer (length 3) vector with the ‘jumps’ (skips) used for these smoothers.

ni  
   number of inner iterations

no  
   number of outer robustness iterations

Note

This is similar to but not identical to the stl function in S-PLUS. The remainder component given by S-PLUS is the sum of the trend and remainder series from this function.

References

See Also

`plot.stl` for `stl` methods; `loess` in package `stats` (which is not actually used in `stl`).

`StructTS` for different kind of decomposition.

Examples

```r
require(graphics)

plot(stl(nottem, "per"))
plot(stl(nottem, s.window = 4, t.window = 50, t.jump = 1))

plot(stllc <- stl(log(co2), s.window = 21))
summary(stllc)
## linear trend, strict period.
plot(stl(log(co2), s.window = "per", t.window = 1000))
## Two STL plotted side by side:
stdm <- stl(mdeaths, s.window = "per") # non-robust
summary(stmR <- stl(mdeaths, s.window = "per", robust = TRUE))
op <- par(mar = c(0, 4, 0, 3), oma = c(5, 0, 4, 0), mfcol = c(4, 2))
plot(stdm, set.pars = NULL, labels = NULL,
main = "stl(mdeaths, s.w = \"per\", robust = FALSE / TRUE ")
plot(stmR, set.pars = NULL)
# mark the 'outliers':
(i0 <- which(stmR $weights < 1e-8)) # 10 were considered outliers
sts <- stmR$time.series
points(time(sts)[i0], 0.8 * sts[,"remainder", i0], pch = 4, col = "red")
par(op) # reset
```

Description

Methods for objects of class `stl`, typically the result of `stl`. The `plot` method does a multiple figure plot with some flexibility.

There are also (non-visible) print and summary methods.

Usage

```r
## S3 method for class 'stl'
plot(x, labels = colnames(X),
    set.pars = list(mar = c(0, 6, 0, 6), oma = c(6, 0, 4, 0),
                   tck = -0.01, mfrow = c(npplot, 1)),
    main = NULL, range.bars = TRUE, ...,
    col.range = "light gray")
```

Arguments

- `x`         `stl` object.
- `labels`    character of length 4 giving the names of the component time-series.
set.pars settings for par(.) when setting up the plot.
main plot main title.
range.bars logical indicating if each plot should have a bar at its right side which are of equal heights in user coordinates.
... further arguments passed to or from other methods.
col.range colour to be used for the range bars, if plotted. Note this appears after ... and so cannot be abbreviated.

plot.ts and stl, particularly for examples.

Description
Fit a structural model for a time series by maximum likelihood.

Usage
StructTS(x, type = c("level", "trend", "BSM"), init = NULL, fixed = NULL, optim.control = NULL)

Arguments
x a univariate numeric time series. Missing values are allowed.
type the class of structural model. If omitted, a BSM is used for a time series with frequency(x) > 1, and a local trend model otherwise.
init initial values of the variance parameters.
fixed optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in fixed will be varied. Probably most useful for setting variances to zero.
optim.control List of control parameters for optim. Method "L-BFGS-B" is used.

Details
Structural time series models are (linear Gaussian) state-space models for (univariate) time series based on a decomposition of the series into a number of components. They are specified by a set of error variances, some of which may be zero.

The simplest model is the local level model specified by type = "level". This has an underlying level \( \mu_t \) which evolves by
\[
\mu_{t+1} = \mu_t + \xi_t, \quad \xi_t \sim N(0, \sigma^2_\xi)
\]
The observations are
\[
x_t = \mu_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma^2_\epsilon)
\]
There are two parameters, \( \sigma^2_\xi \) and \( \sigma^2_\epsilon \). It is an ARIMA(0,1,1) model, but with restrictions on the parameter set.
The local linear trend model, type = "trend", has the same measurement equation, but with a time-varying slope in the dynamics for \( \mu_t \), given by

\[
\mu_{t+1} = \mu_t + \nu_t + \xi_t, \quad \xi_t \sim N(0, \sigma^2_\xi)
\]

\[
\nu_{t+1} = \nu_t + \zeta_t, \quad \zeta_t \sim N(0, \sigma^2_\zeta)
\]

with three variance parameters. It is not uncommon to find \( \sigma^2_\xi = 0 \) (which reduces to the local level model) or \( \sigma^2_\zeta = 0 \), which ensures a smooth trend. This is a restricted ARIMA(0,2,2) model.

The basic structural model, type = "BSM", is a local trend model with an additional seasonal component. Thus the measurement equation is

\[
x_t = \mu_t + \gamma_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma^2_\epsilon)
\]

where \( \gamma_t \) is a seasonal component with dynamics

\[
\gamma_{t+1} = -\gamma_t + \cdots + \gamma_{t-s+2} + \omega_t, \quad \omega_t \sim N(0, \sigma^2_\omega)
\]

The boundary case \( \sigma^2_\omega = 0 \) corresponds to a deterministic (but arbitrary) seasonal pattern. (This is sometimes known as the ‘dummy variable’ version of the BSM.)

**Value**

A list of class "StructTS" with components:

- `coef`: the estimated variances of the components.
- `loglik`: the maximized log-likelihood. Note that as all these models are non-stationary this includes a diffuse prior for some observations and hence is not comparable to `arima` nor different types of structural models.
- `loglik0`: the maximized log-likelihood with the constant used prior to R 3.0.0, for backwards compatibility.
- `data`: the time series `x`.
- `residuals`: the standardized residuals.
- `fitted`: a multiple time series with one component for the level, slope and seasonal components, estimated contemporaneously (that is at time `t` and not at the end of the series).
- `call`: the matched call.
- `series`: the name of the series `x`.
- `code`: the convergence code returned by `optim`.
- `model`, `model0`: Lists representing the Kalman Filter used in the fitting. See `KalmanLike`.
- `xtsp`: the `tsp` attributes of `x`.

**Note**

Optimization of structural models is a lot harder than many of the references admit. For example, the `AirPassengers` data are considered in Brockwell & Davis (1996): their solution appears to be a local maximum, but nowhere near as good a fit as that produced by `StructTS`. It is quite common to find fits with one or more variances zero, and this can include \( \sigma^2_\epsilon \).
summary.aov

References

KalmanLike, tsSmooth; stl for different kind of (seasonal) decomposition.

Examples

```r
## see also JohnsonJohnson, Nile and AirPassengers
require(graphics)

trees <- window(treering, start = 0)
(fit <- StructTS(trees, type = "level"))
plot(trees)
lines(fitted(fit), col = "green")
tsdiag(fit)

(fit <- StructTS(log10(UKgas), type = "BSM"))
par(mfrow = c(4, 1)) # to give appropriate aspect ratio for next plot.
plot(log10(UKgas))
plot(cbind(fitted(fit), resid=resid(fit)), main = "UK gas consumption")

## keep some parameters fixed; trace optimizer:
StructTS(log10(UKgas), type = "BSM", fixed = c(0.1,0.001,NA,NA),
optim.control = list(trace = TRUE))
```

---

**summary.aov**

**Summarize an Analysis of Variance Model**

Description

Summarize an analysis of variance model.

Usage

```r
## S3 method for class 'aov'
summary(object, intercept = FALSE, split,
    expand.split = TRUE, keep.zero.df = TRUE, ...)

## S3 method for class 'aovlist'
summary(object, ...)```
Arguments

object An object of class "aov" or "aovlist".
intercept logical: should intercept terms be included?
split an optional named list, with names corresponding to terms in the model. Each component is itself a list with integer components giving contrasts whose contributions are to be summed.
expand.split logical: should the split apply also to interactions involving the factor?
keep.zero.df logical: should terms with no degrees of freedom be included?
... Arguments to be passed to or from other methods, for summary.aovlist including those for summary.aov.

Value

An object of class c("summary.aov", "listof") or "summary.aovlist" respectively.

For fits with a single stratum the result will be a list of ANOVA tables, one for each response (even if there is only one response): the tables are of class "anova" inheriting from class "data.frame". They have columns "Df", "Sum Sq", "Mean Sq", as well as "F value" and "Pr(>F)" if there are non-zero residual degrees of freedom. There is a row for each term in the model, plus one for "Residuals" if there are any.

For multistratum fits the return value is a list of such summaries, one for each stratum.

Note

The use of expand.split = TRUE is little tested: it is always possible to set it to FALSE and specify exactly all the splits required.

aov, summary, model.tables, TukeyHSD

Examples

## For a simple example see example(aov)

# Cochran and Cox (1957, p.164)
# 3x3 factorial with ordered factors, each is average of 12.
CC <- data.frame(
    y = c(449, 413, 326, 409, 358, 291, 341, 278, 312)/12,
    P = ordered(gl(3, 3)),
    N = ordered(gl(3, 1, 9))
)
CC.aov <- aov(y ~ N * P, data = CC, weights = rep(12, 9))
summary(CC.aov)

# Split both main effects into linear and quadratic parts.
summary(CC.aov, split = list(N = list(L = 1, Q = 2),
    P = list(L = 1, Q = 2)))

# Split only the interaction
summary(CC.aov, split = list("N:P" = list(L.L = 1, Q = 2:4)))

# split on just one var
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)))
summary.glm

```
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)),
        expand.split = FALSE)
```

summary.glm  

**Summarizing Generalized Linear Model Fits**

**Description**

These functions are all methods for class `glm` or `summary.glm` objects.

**Usage**

```r
## S3 method for class 'glm'
summary(object, dispersion = NULL, correlation = FALSE,
         symbolic.cor = FALSE, ...)

## S3 method for class 'summary.glm'
print(x, digits = max(3,getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)
```

**Arguments**

- `object` an object of class "glm", usually, a result of a call to `glm`.
- `x` an object of class "summary.glm", usually, a result of a call to `summary.glm`.
- `dispersion` the dispersion parameter for the family used. Either a single numerical value or `NULL` (the default), when it is inferred from `object` (see 'Details').
- `correlation` logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
- `digits` the number of significant digits to use when printing.
- `symbolic.cor` logical. If TRUE, print the correlations in a symbolic form (see `symnum`) rather than as numbers.
- `signif.stars` logical. If TRUE, 'significance stars' are printed for each coefficient.
- `...` further arguments passed to or from other methods.

**Details**

`print.summary.glm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is TRUE. The coefficients component of the result gives the estimated coefficients and their estimated standard errors, together with their ratio. This third column is labelled `t ratio` if the dispersion is estimated, and `z ratio` if the dispersion is known (or fixed by the family). A fourth column gives the two-tailed p-value corresponding to the `t` or `z` ratio based on a Student `t` or Normal reference distribution. (It is possible that the dispersion is not known and there are no residual degrees of freedom from which to estimate it. In that case the estimate is NaN.)

Aliased coefficients are omitted in the returned object but restored by the `print` method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.
The dispersion of a GLM is not used in the fitting process, but it is needed to find standard errors. If dispersion is not supplied or NULL, the dispersion is taken as 1 for the binomial and Poisson families, and otherwise estimated by the residual Chisquared statistic (calculated from cases with non-zero weights) divided by the residual degrees of freedom.

`summary` can be used with Gaussian `glm` fits to handle the case of a linear regression with known error variance, something not handled by `summary.lm`.

### Value

`summary.glm` returns an object of class "summary.glm", a list with components

- `call` the component from object.
- `family` the component from object.
- `deviance` the component from object.
- `contrasts` the component from object.
- `df.residual` the component from object.
- `null.deviance` the component from object.
- `df.null` the component from object.
- `deviance.resid` the deviance residuals: see `residuals.glm`.
- `coefficients` the matrix of coefficients, standard errors, z-values and p-values. Aliased coefficients are omitted.
- `aliased` named logical vector showing if the original coefficients are aliased.
- `dispersion` either the supplied argument or the inferred/estimated dispersion if the latter is NULL.
- `df` a 3-vector of the rank of the model and the number of residual degrees of freedom, plus number of coefficients (including aliased ones).
- `cov.unscaled` the unscaled (dispersion = 1) estimated covariance matrix of the estimated coefficients.
- `cov.scaled` ditto, scaled by dispersion.
- `correlation` (only if correlation is true.) The estimated correlations of the estimated coefficients.
- `symbolic.cor` (only if correlation is true.) The value of the argument `symbolic.cor`.

### See Also

`glm`, `summary`.

### Examples

```r
## For examples see example(glm)
```
Summary

Summary method for class "lm".

Usage

```r
## S3 method for class 'lm'
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

## S3 method for class 'summary.lm'
print(x, digits = max(3, getOption("digits") - 3),
symbolic.cor = x$symbolic.cor,
signif.stars = getOption("show.signif.stars"), ...)
```

Arguments

- `object`: an object of class "lm", usually, a result of a call to `lm`.
- `x`: an object of class "summary.lm", usually, a result of a call to `summary.lm`.
- `correlation`: logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
- `digits`: the number of significant digits to use when printing.
- `symbolic.cor`: logical. If TRUE, print the correlations in a symbolic form (see `symnum`) rather than as numbers.
- `signif.stars`: logical. If TRUE, 'significance stars' are printed for each coefficient.
- `...`: further arguments passed to or from other methods.

Details

`print.summary.lm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is TRUE.

Aliased coefficients are omitted in the returned object but restored by the `print` method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

Value

The function `summary.lm` computes and returns a list of summary statistics of the fitted linear model given in `object`, using the components (list elements) "call" and "terms" from its argument, plus

- `residuals`: the weighted residuals, the usual residuals rescaled by the square root of the weights specified in the call to `lm`.
- `coefficients`: a p × 4 matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value. Aliased coefficients are omitted.
- `aliased`: named logical vector showing if the original coefficients are aliased.
sigma

the square root of the estimated variance of the random error

$$\hat{\sigma}^2 = \frac{1}{n-p} \sum_i w_i R_i^2,$$

where $R_i$ is the $i$-th residual, residuals[i].

df

degrees of freedom, a 3-vector $(p, n-p, p^*)$, the first being the number of non-aliased coefficients, the last being the total number of coefficients.

fstatistic

(for models including non-intercept terms) a 3-vector with the value of the F-statistic with its numerator and denominator degrees of freedom.

r.squared

$R^2$, the ‘fraction of variance explained by the model’,

$$R^2 = 1 - \frac{\sum_i R_i^2}{\sum_i (y_i - \bar{y})^2},$$

where $\bar{y}$ is the mean of $y_i$ if there is an intercept and zero otherwise.

adj.r.squared

the above $R^2$ statistic ‘adjusted’, penalizing for higher $p$.

cov.unscaled

a $p \times p$ matrix of (unscaled) covariances of the $\hat{\beta}_j, j = 1, \ldots, p$.

correlation

the correlation matrix corresponding to the above cov.unscaled, if correlation = TRUE is specified.

symbolic.cor

(only if correlation is true.) The value of the argument symbolic.cor.

na.action

from object, if present there.

See Also

The model fitting function lm, summary.

Function coef will extract the matrix of coefficients with standard errors, t-statistics and p-values.

Examples

```r
#--- Continuing the lm(.) example:
coef(lm.D90) # the bare coefficients
sld90 <- summary(lm.D90 <- lm(weight ~ group -1)) # omitting intercept
sld90
coef(sld90) # much more

# model with *aliased* coefficient:
lm.D9. <- lm(weight ~ group + I(group != "Ctl"))
Sm.D9. <- summary(lm.D9.)
Sm.D9. # shows the NA NA NA NA line
stopifnot(length(cc <- coef(lm.D9.)) == 3, is.na(cc[3]),
  dim(coef(Sm.D9.)) == c(2,4), Sm.D9.$df == c(2, 18, 3))
```
**Description**

A summary method for class "manova".

**Usage**

```r
## S3 method for class 'manova'
summary(object, 
  test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy"), 
  intercept = FALSE, tol = 1e-7, ...)
```

**Arguments**

- `object` An object of class "manova" or an `aov` object with multiple responses.
- `test` The name of the test statistic to be used. Partial matching is used so the name can be abbreviated.
- `intercept` logical. If `TRUE`, the intercept term is included in the table.
- `tol` tolerance to be used in deciding if the residuals are rank-deficient: see `qr`.
- `...` further arguments passed to or from other methods.

**Details**

The `summary.manova` method uses a multivariate test statistic for the summary table. Wilks’ statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987).

The table gives a transformation of the test statistic which has approximately an F distribution. The approximations used follow S-PLUS and SAS (the latter apart from some cases of the Hotelling–Lawley statistic), but many other distributional approximations exist: see Anderson (1984) and Krzanowski and Marriott (1994) for further references. All four approximate F statistics are the same when the term being tested has one degree of freedom, but in other cases that for the Roy statistic is an upper bound.

The tolerance `tol` is applied to the QR decomposition of the residual correlation matrix (unless some response has essentially zero residuals, when it is unscaled). Thus the default value guards against very highly correlated responses: it can be reduced but doing so will allow rather inaccurate results and it will normally be better to transform the responses to remove the high correlation.

**Value**

An object of class "summary.manova". If there is a positive residual degrees of freedom, this is a list with components

- `row.names` The names of the terms, the row names of the `stats` table if present.
- `SS` A named list of sums of squares and product matrices.
- `Eigenvalues` A matrix of eigenvalues.
- `stats` A matrix of the statistics, approximate F value, degrees of freedom and P value.

otherwise components `row.names`, `SS` and `Df` (degrees of freedom) for the terms (and not the residuals).

Examples

```r
## Example on producing plastic film from Krzanowski (1998, p. 381)
tear <- c(6.5, 6.2, 5.8, 6.5, 6.5, 6.9, 7.2, 6.9, 6.1, 6.3,
          6.7, 6.6, 7.2, 7.1, 6.8, 7.1, 7.0, 7.2, 7.5, 7.6)
gloss <- c(9.5, 9.9, 9.6, 9.6, 9.2, 9.1, 10.0, 9.9, 9.5, 9.4,
          9.1, 9.3, 8.3, 8.4, 8.5, 9.2, 8.8, 9.7, 10.1, 9.2)
opacity <- c(4.4, 6.4, 3.0, 4.1, 0.8, 5.7, 2.0, 3.9, 1.9, 5.7,
            2.8, 4.1, 3.8, 1.6, 3.4, 8.4, 5.2, 6.9, 2.7, 1.9)
Y <- cbind(tear, gloss, opacity)
rate <- factor(gl(2,10), labels = c("Low", "High"))
additive <- factor(gl(2, 5, length = 20), labels = c("Low", "High"))

fit <- manova(Y ~ rate * additive)
summary.aov(fit)  # univariate ANOVA tables
summary(fit, test = "Wilks")  # ANOVA table of Wilks' lambda
summary(fit)       # same F statistics as single-df terms
```

**summary.nls**

*Summarizing Non-Linear Least-Squares Model Fits*

**Description**

`summary` method for class "nls".

**Usage**

```r
## S3 method for class 'nls'
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

## S3 method for class 'summary.nls'
print(x, digits = max(3,getOption("digits") - 3),
       symbolic.cor =getOption("show.symbolic.cor"),
       signif.stars =getOption("show.signif.stars"), ...)
```
Arguments

- **object**: an object of class "nls".
- **x**: an object of class "summary.nls", usually the result of a call to `summary.nls`.
- **correlation**: logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
- **digits**: the number of significant digits to use when printing.
- **symbolic.cor**: logical. If TRUE, print the correlations in a symbolic form (see `symnum`) rather than as numbers.
- **signif.stars**: logical. If TRUE, ‘significance stars’ are printed for each coefficient.
- **...**: further arguments passed to or from other methods.

Details

The distribution theory used to find the distribution of the standard errors and of the residual standard error (for t ratios) is based on linearization and is approximate, maybe very approximate.

`print.summary.nls` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives ‘significance stars’ if `signif.stars` is TRUE.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

Value

The function `summary.nls` computes and returns a list of summary statistics of the fitted model given in `object`, using the component "formula" from its argument, plus

- **residuals**: the weighted residuals, the usual residuals rescaled by the square root of the weights specified in the call to `nls`.
- **coefficients**: a \( p \times 4 \) matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value.
- **sigma**: the square root of the estimated variance of the random error

\[
\hat{\sigma}^2 = \frac{1}{n - p} \sum_i R_i^2,
\]

where \( R_i \) is the \( i \)-th weighted residual.

- **df**: degrees of freedom, a 2-vector \((p, n - p)\). (Here and elsewhere \( n \) omits observations with zero weights.)
- **cov.unscaled**: a \( p \times p \) matrix of (unscaled) covariances of the parameter estimates.
- **correlation**: the correlation matrix corresponding to the above `cov.unscaled`, if `correlation = TRUE` is specified and there are a non-zero number of residual degrees of freedom.
- **symbolic.cor**: (only if `correlation` is true.) The value of the argument `symbolic.cor`.

See Also

The model fitting function `nls, summary`.

Function `coef` will extract the matrix of coefficients with standard errors, t-statistics and p-values.
summary.princomp

Summary method for Principal Components Analysis

Description

The `summary` method for class "princomp".

Usage

```r
## S3 method for class 'princomp'
summary(object, loadings = FALSE, cutoff = 0.1, ...)

## S3 method for class 'summary.princomp'
print(x, digits = 3, loadings = x$print.loadings,
      cutoff = x$cutoff, ...)
```

Arguments

- `object` an object of class "princomp", as from `princomp()`.
- `loadings` logical. Should loadings be included?
- `cutoff` numeric. Loadings below this cutoff in absolute value are shown as blank in the output.
- `x` an object of class "summary.princomp".
- `digits` the number of significant digits to be used in listing loadings.
- `...` arguments to be passed to or from other methods.

Value

`object` with additional components `cutoff` and `print.loadings`.

See Also

`princomp`

Examples

```r
summary(pc.cr <- princomp(USArrests, cor = TRUE))
## The signs of the loading columns are arbitrary
print(summary(princomp(USArrests, cor = TRUE),
         loadings = TRUE, cutoff = 0.2), digits = 2)
```
**supsmu**

*Friedman’s SuperSmoother*

**Description**

Smooth the \((x, y)\) values by Friedman’s ‘super smoother’.

**Usage**

\[
supsmu(x, y, wt, span = "cv", periodic = FALSE, bass = 0)
\]

**Arguments**

- **x**  
  x values for smoothing
- **y**  
  y values for smoothing
- **wt**  
  case weights, by default all equal
- **span**  
  the fraction of the observations in the span of the running lines smoother, or "cv" to choose this by leave-one-out cross-validation.
- **periodic**  
  if TRUE, the x values are assumed to be in \([0, 1]\) and of period 1.
- **bass**  
  controls the smoothness of the fitted curve. Values of up to 10 indicate increasing smoothness.

**Details**

`supsmu` is a running lines smoother which chooses between three spans for the lines. The running lines smoothers are symmetric, with \(k/2\) data points each side of the predicted point, and values of \(k\) as \(0.5 \times n, 0.2 \times n\) and \(0.05 \times n\), where \(n\) is the number of data points. If `span` is specified, a single smoother with `span` \(\times n\) is used.

The best of the three smoothers is chosen by cross-validation for each prediction. The best spans are then smoothed by a running lines smoother and the final prediction chosen by linear interpolation.

The FORTRAN code says: “For small samples \((n < 40)\) or if there are substantial serial correlations between observations close in x-value, then a pre-specified fixed span smoother \((\text{span} > 0)\) should be used. Reasonable span values are 0.2 to 0.4.”

Cases with non-finite values of \(x, y\) or \(wt\) are dropped, with a warning.

**Value**

A list with components

- **x**  
  the input values in increasing order with duplicates removed.
- **y**  
  the corresponding y values on the fitted curve.

**References**

Examples

```r
require(graphics)

with(cars, {
  plot(speed, dist)
  lines(supsmu(speed, dist))
  lines(supsmu(speed, dist, bass = 7), lty = 2)
})
```

symnum

Symbolic Number Coding

Description

Symbolically encode a given numeric or logical vector or array. Particularly useful for visualization of structured matrices, e.g., correlation, sparse, or logical ones.

Usage

```r
symnum(x, cutpoints = c(0.3, 0.6, 0.8, 0.9, 0.95),
   symbols = if(numeric.x) c("\", ".", ",", "+", "x", "B")
   else c("\", ","),
   legend = length(symbols) >= 3,
   na = "?", eps = 1e-5, numeric.x = is.numeric(x),
   corr = missing(cutpoints) && numeric.x,
   show.max = if(corr) "1", show.min = NULL,
   abbr.colnames = has.colnames,
   lower.triangular = corr && is.numeric(x) && is.matrix(x),
   diag.lower.tri = corr && !is.null(show.max))
```

Arguments

- `x` numeric or logical vector or array.
- `cutpoints` numeric vector whose values `cutpoints[j] = c_j` (after augmentation, see corr below) are used for intervals.
- `symbols` character vector, one shorter than (the augmented, see corr below) cutpoints. symbols[j]= s_j are used as ‘code’ for the (half open) interval (c_j,c_j+1] . When numeric.x is FALSE, i.e., by default when argument x is logical, the default is c("\", ","), (graphical 0 / 1 s).
- `legend` logical indicating if a "legend" attribute is desired.
- `na` character or logical. How NAs are coded. If na == FALSE, NAs are coded invisibly, including the "legend" attribute below, which otherwise mentions NA coding.
- `eps` absolute precision to be used at left and right boundary.
- `numeric.x` logical indicating if x should be treated as numbers, otherwise as logical.
symnum

corr logical. If TRUE, x contains correlations. The cutpoints are augmented by 0 and 1 and abs(x) is coded.

show.max if TRUE, or of mode character, the maximal cutpoint is coded especially.

show.min if TRUE, or of mode character, the minimal cutpoint is coded especially.

abbr.colnames logical, integer or NULL indicating how column names should be abbreviated (if they are); if NULL (or FALSE and x has no column names), the column names will all be empty, i.e., ""; otherwise if abbr.colnames is false, they are left unchanged. If TRUE or integer, existing column names will be abbreviated to abbreviate(*, minlength = abbr.colnames).

lower.triangular logical. If TRUE and x is a matrix, only the lower triangular part of the matrix is coded as non-blank.

diag.lower.tri logical. If lower.triangular and this are TRUE, the diagonal part of the matrix is shown.

Value

An atomic character object of class noquote and the same dimensions as x.

If legend is TRUE (as by default when there are more than two classes), the result has an attribute "legend" containing a legend of the returned character codes, in the form

\[ c_1 s_1 c_2 s_2 \ldots c_n s_{n+1} \]

where \( c_j \) = cutpoints[j] and \( s_j \) = symbols[j].

Note

The optional (mostly logical) arguments all try to use smart defaults. Specifying them explicitly may lead to considerably improved output in many cases.

Examples

```r
ii <- setNames(0:8, 0:8)
symnum(ii, cut = 2*(0:4), sym = c("accine", "-n", "+n", ",\$\))
symnum(ii, cut = 2*(0:4), sym = c("accine", "-n", "+n", ",\$\), show.max = TRUE)
symnum(1:12 %% 3 == 0) # --> ",\$\" = TRUE, ",\$\" = FALSE for logical

## Pascal's Triangle modulo 2 -- odd and even numbers:
N <- 38
pascal <- t(sapply(0:N, function(n) round(choose(n, 0:N - (N-n)%/%2)))))
rownames(pascal) <- rep("accine", 1+N) # -- to improve "graphic"
symnum(pascal %% 2, symbols = c("accine", "A"), numeric = FALSE)

##-- Symbolic correlation matrices:
```

**t.test**

**Student’s t-Test**

**Description**

Performs one and two sample t-tests on vectors of data.

**Usage**

t.test(x, ...)

---

**Arguments**

- **x**: a (non-empty) numeric vector of data values.
- **y**: an optional (non-empty) numeric vector of data values.
- **alternative**: a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
- **mu**: a number indicating the true value of the mean (or difference in means if you are performing a two sample test).
paired  a logical indicating whether you want a paired t-test.

var.equal  a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.

conf.level  confidence level of the interval.

formula  a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.

data  an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset  an optional vector specifying a subset of observations to be used.

na.action  a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").

...  further arguments to be passed to or from methods.

Details

The formula interface is only applicable for the 2-sample tests.

alternative = "greater" is the alternative that x has a larger mean than y.

If paired is TRUE then both x and y must be specified and they must be the same length. Missing values are silently removed (in pairs if paired is TRUE). If var.equal is TRUE then the pooled estimate of the variance is used. By default, if var.equal is FALSE then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.

If the input data are effectively constant (compared to the larger of the two means) an error is generated.

Value

A list with class "htest" containing the following components:

statistic  the value of the t-statistic.

parameter  the degrees of freedom for the t-statistic.

p.value  the p-value for the test.

conf.int  a confidence interval for the mean appropriate to the specified alternative hypothesis.

estimate  the estimated mean or difference in means depending on whether it was a one-sample test or a two-sample test.

null.value  the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test.

alternative  a character string describing the alternative hypothesis.

method  a character string indicating what type of t-test was performed.

data.name  a character string giving the name(s) of the data.

See Also

prop.test
Examples

```r
require(graphics)

t.test(1:10, y = c(7:20))  # P = .00001855

t.test(1:10, y = c(7:20, 200)) # P = .1245 -- NOT significant anymore

### Classical example: Student’s sleep data
plot(extra ~ group, data = sleep)
### Traditional interface
with(sleep, t.test(extra[group == 1], extra[group == 2]))
### Formula interface

t.test(extra ~ group, data = sleep)
```

**TDist**

_The Student t Distribution_

**Description**

Density, distribution function, quantile function and random generation for the t distribution with \( df \) degrees of freedom (and optional non-centrality parameter \( ncp \)).

**Usage**

```r
dt(x, df, ncp, log = FALSE)
pt(q, df, ncp, lower.tail = TRUE, log.p = FALSE)
qt(p, df, ncp, lower.tail = TRUE, log.p = FALSE)
rt(n, df, ncp)
```

**Arguments**

- **x, q** vector of quantiles.
- **p** vector of probabilities.
- **n** number of observations. If `length(n) > 1`, the length is taken to be the number required.
- **df** degrees of freedom (> 0, maybe non-integer). \( df = \text{Inf} \) is allowed.
- **ncp** non-centrality parameter \( \delta \); currently except for \( \text{rt()} \), only for \( \text{abs(ncp)} < 37.62 \). If omitted, use the central t distribution.
- **log, log.p** logical; if TRUE, probabilities p are given as log(p).
- **lower.tail** logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

**Details**

The t distribution with \( df = \nu \) degrees of freedom has density

\[
f(x) = \frac{\Gamma((\nu + 1)/2)}{\sqrt{\pi \nu \Gamma(\nu/2)}} \left(1 + x^2/\nu\right)^{-(\nu+1)/2}
\]

for all real \( x \). It has mean 0 (for \( \nu > 1 \)) and variance \( \frac{\nu}{\nu-2} \) (for \( \nu > 2 \)).

The general non-central t with parameters \((\nu, \delta) = (df, ncp)\) is defined as the distribution of \( T_{\nu}(\delta) := (U + \delta)/\sqrt{V/\nu} \) where \( U \) and \( V \) are independent random variables, \( U \sim N(0,1) \) and \( V \sim \chi^2_\nu \) (see Chisquare).
The most used applications are power calculations for $t$-tests:

Let $T = \frac{\bar{X} - \mu_0}{S/\sqrt{n}}$ where $\bar{X}$ is the mean and $S$ the sample standard deviation (sd) of $X_1, X_2, \ldots, X_n$ which are i.i.d. $\mathcal{N}(\mu, \sigma^2)$. Then $T$ is distributed as non-central $t$ with $df = n - 1$ degrees of freedom and non-centrality parameter $ncp = (\mu - \mu_0)\sqrt{n}/\sigma$.

**Value**

dt gives the density, pt gives the distribution function, qt gives the quantile function, and rt generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by $n$ for rt, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than $n$ are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

Supplying $ncp = 0$ uses the algorithm for the non-central distribution, which is not the same algorithm used if $ncp$ is omitted. This is to give consistent behaviour in extreme cases with values of $ncp$ very near zero.

The code for non-zero $ncp$ is principally intended to be used for moderate values of $ncp$: it will not be highly accurate, especially in the tails, for large values.

**Source**

The central dt is computed via an accurate formula provided by Catherine Loader (see the reference in dbinom).

For the non-central case of dt, C code contributed by Claus Ekstrøm based on the relationship (for $x \neq 0$) to the cumulative distribution.

For the central case of pt, a normal approximation in the tails, otherwise via pbeta.

For the non-central case of pt based on a C translation of

This computes the lower tail only, so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant.

For central qt, a C translation of

altered to take account of

The non-central case is done by inversion.

Distributions for other standard distributions, including df for the F distribution.

Examples

```
require(graphics)

1 - pt(1:5, df = 1)
qt(.975, df = c(1:10,20,50,100,1000))

tt <- seq(0, 10, len = 21)
ncp <- seq(0, 6, len = 31)
ptn <- outer(tt, ncp, function(t, d) pt(t, df = 3, ncp = d))
t.tit <- "Non-central t - Probabilities"
image(tt, ncp, ptn, zlim = c(0,1), main = t.tit)
persp(tt, ncp, ptn, zlim = 0:1, r = 2, phi = 20, theta = 200, main = t.tit,
     xlab = "t", ylab = "non-centrality parameter",
     zlab = "Pr(T <= t)"

plot(function(x) dt(x, df = 3, ncp = 2), -3, 3, ylim = c(0, 0.32),
     main = "Non-central t - Density", yaxs = "i")
```

**termplot**

Plot Regression Terms

Description

Plots regression terms against their predictors, optionally with standard errors and partial residuals added.

Usage

```
termplot(model, data = NULL, envir = environment(formula(model)),
    partial.resid = FALSE, rug = FALSE,
    terms = NULL, se = FALSE,
    xlabs = NULL, ylabs = NULL, main = NULL,
    col.term = 2, lwd.term = 1.5,
    col.se = "orange", lty.se = 2, lwd.se = 1,
    col.res = "gray", cex = 1, pch = par("pch"),
    col.smth = "darkred", lty.smth = 2, span.smth = 2/3,
    ask = dev.interactive() & nb.fig < n.tms,
use.factor.levels = TRUE, smooth = NULL, ylim = "common",
    plot = TRUE, transform.x = FALSE, ...)
```

Arguments

- **model**: fitted model object
- **data**: data frame in which variables in model can be found
- **envir**: environment in which variables in model can be found
- **partial.resid**: logical; should partial residuals be plotted?
- **rug**: add rugplots (jittered 1-d histograms) to the axes?
The model object must have a predict method that accepts type = "terms", e.g., glm in the stats package, coxph and survreg in the survival package.

For the partial.resid = TRUE option model must have a residuals method that accepts type = "partial", which lm and glm do.

The data argument should rarely be needed, but in some cases termplot may be unable to reconstruct the original data frame. Using na.action=na.exclude makes these problems less likely.

Nothing sensible happens for interaction terms, and they may cause errors.

The plot = FALSE option is useful when some special action is needed, e.g. to overlay the results of two different models or to plot confidence bands.
Value

For plot = FALSE, a list with one element for each plot which would have been produced. Each element of the list is a data frame with variables x, y, and optionally the pointwise standard errors se. For continuous predictors x will contain the ordered unique values and for a factor it will be a factor containing one instance of each level. The list has attribute "constant" copied from the predicted terms object.

Otherwise, the number of terms, invisibly.

  smooth=panel.smooth)
}

<table>
<thead>
<tr>
<th>terms</th>
<th>Model Terms</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

The function terms is a generic function which can be used to extract terms objects from various kinds of R data objects.

Usage

terms(x, ...)

terms.formula

Arguments

x object used to select a method to dispatch.
...

Details

There are methods for classes "aovlist", and "terms" "formula" (see terms.formula): the default method just extracts the terms component of the object, or failing that a "terms" attribute (as used by model.frame).

There are print and labels methods for class "terms": the latter prints the term labels (see terms.object).

Value

An object of class c("terms", "formula") which contains the terms representation of a symbolic model. See terms.object for its structure.

References

See Also

terms.object, terms.formula.lm, glm.formula.

terms.formula Construct a terms Object from a Formula

Description

This function takes a formula and some optional arguments and constructs a terms object. The terms object can then be used to construct a model.matrix.

Usage

## S3 method for class 'formula'
terms(x, specials = NULL, abb = NULL, data = NULL, neg.out = TRUE,
keep.order = FALSE, simplify = FALSE, ...,
allowDotAsName = FALSE)

Arguments

x a formula.
specials which functions in the formula should be marked as special in the terms object? A character vector or NULL.
abb Not implemented in R.
data a data frame from which the meaning of the special symbol . can be inferred. It is unused if there is no . in the formula.
neg.out Not implemented in R.
terms.object

keep.order a logical value indicating whether the terms should keep their positions. If FALSE
the terms are reordered so that main effects come first, followed by the interac-
tions, all second-order, all third-order and so on. Effects of a given order are
kept in the order specified.

simplify should the formula be expanded and simplified, the pre-1.7.0 behaviour?

... further arguments passed to or from other methods.

allowDotAsName normally . in a formula refers to the remaining variables contained in data.
Exceptionally, . can be treated as a name for non-standard uses of formulae.

Details

Not all of the options work in the same way that they do in S and not all are implemented.

Value

A terms.object object is returned. The object itself is the re-ordered (unless keep.order = TRUE)
formula. In all cases variables within an interaction term in the formula are re-ordered by the order-
ing of the “variables” attribute, which is the order in which the variables occur in the formula.

See Also

terms, terms.object

terms.object Description of Terms Objects

Description

An object of class terms holds information about a model. Usually the model was specified in
terms of a formula and that formula was used to determine the terms object.

Value

The object itself is simply the formula supplied to the call of terms.formula. The object has a
number of attributes and they are used to construct the model frame:

factors A matrix of variables by terms showing which variables appear in which terms.
The entries are 0 if the variable does not occur in the term, 1 if it does occur
and should be coded by contrasts, and 2 if it occurs and should be coded via
dummy variables for all levels (as when a lower-order term is missing). Note
that variables in main effects always receive 1, even if the intercept is missing
(in which case the first one should be coded with dummy variables). If there are
no terms other than an intercept and offsets, this is numeric(0).

term.labels A character vector containing the labels for each of the terms in the model,
except for offsets. Note that these are after possible re-ordering of terms.
Non-syntactic names will be quoted by backticks: this makes it easier to re-
construct the formula from the term labels.

variables A call to list of the variables in the model.

intercept Either 0, indicating no intercept is to be fit, or 1 indicating that an intercept is to
be fit.
**time**

**Sampling Times of Time Series**

time creates the vector of times at which a time series was sampled.

cycle gives the positions in the cycle of each observation.

frequency returns the number of samples per unit time and delt at the time interval between observations (see ts).

**order**
A vector of the same length as term.labels indicating the order of interaction for each term.

**response**
The index of the variable (in variables) of the response (the left hand side of the formula). Zero, if there is no response.

**offset**
If the model contains offset terms there is an offset attribute indicating which variable(s) are offsets.

**specials**
If a specials argument was given to terms.formula there is a specials attribute, a pairlist of vectors (one for each specified special function) giving numeric indices of the arguments of the list returned as the variables attribute which contain these special functions.

**dataClasses**
optional. A named character vector giving the classes (as given by .MFclass) of the variables used in a fit.

**predvars**
optional. An expression to help in computing predictions at new covariate values; see makepredictcall.

The object has class c("terms", "formula").

**Note**
These objects are different from those found in S. In particular there is no formula attribute: instead the object is itself a formula. (Thus, the mode of a terms object is different.)

Examples of the specials argument can be seen in the aov and coxph functions, the latter from package survival.

**See Also**
terms, formula.

**Examples**

```r
## use of specials (as used for gam() in packages mgcv and gam)
(tf <- terms(y ~ x + x:x + s(x), specials = "s"))
## Note that the "factors" attribute has variables as row names
## and term labels as column names, both as character vectors.
attr(tf, "specials")  # index 's' variable(s)
rownames(attr(tf, "factors"))[attr(tf, "specials")$s]

## we can keep the order by
terms(y ~ x + x:x + s(x), specials = "s", keep.order = TRUE)
```

---

**time**

Sampling Times of Time Series

time creates the vector of times at which a time series was sampled.

cycle gives the positions in the cycle of each observation.

frequency returns the number of samples per unit time and delt at the time interval between observations (see ts).
toeplitz

Usage

time(x, ...)  
## Default S3 method:  
time(x, offset = 0, ...)  

cycle(x, ...)  
frequency(x, ...)  
deltat(x, ...)  

Arguments

x  
a univariate or multivariate time-series, or a vector or matrix.  

offset  
can be used to indicate when sampling took place in the time unit. 0 (the default) indicates the start of the unit, 0.5 the middle and 1 the end of the interval.  

...  
extra arguments for future methods.  

Details

These are all generic functions, which will use the tsp attribute of x if it exists. time and cycle have methods for class ts that coerce the result to that class.  

References

See Also

*ts, start, tsp, window.*  
date for clock time, system.time for CPU usage.  

Examples

```r  
require(graphics)  

cycle(presidents)  
# a simple series plot  
plot(as.vector(time(presidents)), as.vector(presidents), type = "l")  
```

---

**toeplitz**  
*Form Symmetric Toeplitz Matrix*

Description

Forms a symmetric Toeplitz matrix given its first row.  

Usage

toeplitz(x, ...)
Arguments

- `x`: the first row to form the Toeplitz matrix.
- `...`: potential further arguments (for methods); none here.

Value

The Toeplitz matrix.

Author(s)

A. Trapletti

Examples

```r
x <- 1:5
toeplitz(x)
```

Description

The function `ts` is used to create time-series objects. `as.ts` and `is.ts` coerce an object to a time-series and test whether an object is a time series.

Usage

```r
ts(data = NA, start = 1, end = numeric(), frequency = 1,
    deltat = 1, ts.eps = getOption("ts.eps"), class = , names = )
as.ts(x, ...)
is.ts(x)
```

Arguments

- `data`: a vector or matrix of the observed time-series values. A data frame will be coerced to a numeric matrix via `data.matrix`. (See also ‘Details’.)
- `start`: the time of the first observation. Either a single number or a vector of two integers, which specify a natural time unit and a (1-based) number of samples into the time unit. See the examples for the use of the second form.
- `end`: the time of the last observation, specified in the same way as `start`.
- `frequency`: the number of observations per unit of time.
- `deltat`: the fraction of the sampling period between successive observations; e.g., 1/12 for monthly data. Only one of `frequency` or `deltat` should be provided.
- `ts.eps`: time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than `ts.eps`.
- `class`: class to be given to the result, or none if `NULL` or "none". The default is "ts" for a single series, `c("mts", "ts", "matrix")` for multiple series.
- `names`: a character vector of names for the series in a multiple series: defaults to the colnames of `data`, or `Series 1, Series 2, ....`
- `x`: an arbitrary `R` object.
- `...`: arguments passed to methods (unused for the default method).
Details

The function `ts` is used to create time-series objects. These are vector or matrices with class of "ts" (and additional attributes) which represent data which has been sampled at equispaced points in time. In the matrix case, each column of the matrix data is assumed to contain a single (univariate) time series. Time series must have at least one observation, and although they need not be numeric there is very limited support for non-numeric series.

Class "ts" has a number of methods. In particular arithmetic will attempt to align time axes, and subsetting to extract subsets of series can be used (e.g., `EuStockMarkets[, "DAX"]`). However, subsetting the first (or only) dimension will return a matrix or vector, as will matrix subsetting. Subassignment can be used to replace values but not to extend a series (see `window`). There is a method for `t` that transposes the series as a matrix (a one-column matrix if a vector) and hence returns a result that does not inherit from class "ts".

The value of argument `frequency` is used when the series is sampled an integral number of times in each unit time interval. For example, one could use a value of 7 for `frequency` when the data are sampled daily, and the natural time period is a week, or 12 when the data are sampled monthly and the natural time period is a year. Values of 4 and 12 are assumed in (e.g.) print methods to imply a quarterly and monthly series respectively.

`as.ts` is generic. Its default method will use the `tsp` attribute of the object if it has one to set the start and end times and frequency.

`is.ts` tests if an object is a time series. It is generic: you can write methods to handle specific classes of objects, see `InternalMethods`.

References

See Also

`tsp`, `frequency`, `start`, `end`, `time`, `window`; `print.ts`, the print method for time series objects; `plot.ts`, the plot method for time series objects.

For other definitions of 'time series' (e.g., time-ordered observations) see the CRAN task view at http://cran.r-project.org/web/views/TimeSeries.html.

Examples

```r
require(graphics)

ts(1:10, frequency = 4, start = c(1959, 2)) # 2nd Quarter of 1959
p

## Using July 1954 as start date:
gnp <- ts(csum(1 + round(rnorm(100), 2)),
          start = c(1954, 7), frequency = 12)
plot(gnp) # using 'plot.ts' for time-series plot

## Multivariate
z <- ts(matrix(rnorm(300), 100, 3), start = c(1961, 1), frequency = 12)
class(z)
head(z) # as "matrix"
plot(z)
plot(z, plot.type = "single", lty = 1:3)
```
### A phase plot:
```r
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",
     main = "Lag plot of New Haven temperatures")
```
ts.plot  

Plot Multiple Time Series

Description
Plot several time series on a common plot. Unlike `plot.ts` the series can have a different time bases, but they should have the same frequency.

Usage
`ts.plot(..., gpars = list())`

Arguments
- `...`: one or more univariate or multivariate time series.
- `gpars`: list of named graphics parameters to be passed to the plotting functions. Those commonly used can be supplied directly in `...`

Value
None.

Note
Although this can be used for a single time series, `plot.ts` is easier to use and is preferred.

See Also
- `plot.ts`

Examples
```r
require(graphics)

ts.plot(ldeaths, mdeaths, fdeaths,
        gpars=list(xlab="year", ylab="deaths", lty=c(1:3)))
```

---

ts.union  

Bind Two or More Time Series

Description
Bind time series which have a common frequency. `ts.union` pads with NAs to the total time coverage, `ts.intersect` restricts to the time covered by all the series.

Usage
```r
ts.intersect(..., dframe = FALSE)
ts.union(..., dframe = FALSE)
```
Arguments

... two or more univariate or multivariate time series, or objects which can coerced to time series.
dframe logical; if TRUE return the result as a data frame.

Details

As a special case, ... can contain vectors or matrices of the same length as the combined time series of the time series present, as well as those of a single row.

Value

A time series object if dframe is FALSE, otherwise a data frame.

See Also

cbind.

Examples

ts.union(mdeaths, fdeaths)
cbind(mdeaths, fdeaths) # same as the previous line
ts.intersect(window(mdeaths, 1976), window(fdeaths, 1974, 1978))

sales1 <- ts.union(BJsales, lead = BJsales.lead)
ts.intersect(sales1, lead3 = lag(BJsales.lead, -3))
Value

None. Diagnostics are plotted.

tsp

Tsp Attribute of Time-Series-like Objects

Description

tsp returns the tsp attribute (or NULL). It is included for compatibility with S version 2. tsp<- sets the tsp attribute. hasTsp ensures x has a tsp attribute, by adding one if needed.

Usage

tsp(x)
tsp(x) <- value
hasTsp(x)

Arguments

x a vector or matrix or univariate or multivariate time-series.
value a numeric vector of length 3 or NULL.

Details

The tsp attribute gives the start time in time units, the end time and the frequency (the number of observations per unit of time, e.g. 12 for a monthly series).
Assignments are checked for consistency.
Assigning NULL which removes the tsp attribute and any "ts" (or "mts") class of x.

Value

An object which differs from x only in the tsp attribute (unless NULL is assigned).
hasTsp adds, if needed, an attribute with a start time and frequency of 1 and end time NROW(x).
tsSmooth

ts, time, start.

---

Use Fixed-Interval Smoothing on Time Series

Description

Performs fixed-interval smoothing on a univariate time series via a state-space model. Fixed-interval smoothing gives the best estimate of the state at each time point based on the whole observed series.

Usage

tsSmooth(object, ...)

Arguments

object a time-series fit. Currently only class "StructTS" is supported
... possible arguments for future methods.

Value

A time series, with as many dimensions as the state space and results at each time point of the original series. (For seasonal models, only the current seasonal component is returned.)

Author(s)

B. D. Ripley

The Studentized Range Distribution

Description

Functions of the distribution of the studentized range, $R/s$, where $R$ is the range of a standard normal sample and $df \times s^2$ is independently distributed as chi-squared with $df$ degrees of freedom, see \texttt{pchisq}.

Usage

\begin{verbatim}
ptukey(q, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
qtukey(p, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
\end{verbatim}

Arguments

- \texttt{q} vector of quantiles.
- \texttt{p} vector of probabilities.
- \texttt{nmeans} sample size for range (same for each group).
- \texttt{df} degrees of freedom for $s$ (see below).
- \texttt{nranges} number of groups whose maximum range is considered.
- \texttt{log.p} logical; if TRUE, probabilities \texttt{p} are given as \texttt{log(p)}.
- \texttt{lower.tail} logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

If $n_g = nranges$ is greater than one, $R$ is the maximum of $n_g$ groups of $nmeans$ observations each.

Value

\texttt{ptukey} gives the distribution function and \texttt{qtukey} its inverse, the quantile function.

The length of the result is the maximum of the lengths of the numerical arguments. The other numerical arguments are recycled to that length. Only the first elements of the logical arguments are used.

Note

A Legendre 16-point formula is used for the integral of ptukey. The computations are relatively expensive, especially for \texttt{qtukey} which uses a simple secant method for finding the inverse of ptukey. \texttt{qtukey} will be accurate to the 4th decimal place.

Source

\texttt{qtukey} is in part adapted from Odeh and Evans (1974).
TukeyHSD

References

See Also

*Distributions* for standard distributions, including `pnorm` and `qnorm` for the corresponding functions for the normal distribution.

Examples

```r
if(interactive())
  curve(ptukey(x, nn = 6, df = 5), from = -1, to = 8, n = 101)
  (ptt <- ptukey(0.10, 2, df = 5))
  (qtt <- qtukey(.95, 2, df = 2:11))
  ## The precision may be not much more than about 8 digits:
  summary(abs(.95 - ptukey(qtt, 2, df = 2:11)))
```

TukeyHSD

*Compute Tukey Honest Significant Differences*

Description

Create a set of confidence intervals on the differences between the means of the levels of a factor with the specified family-wise probability of coverage. The intervals are based on the Studentized range statistic, Tukey’s ‘Honest Significant Difference’ method.

Usage

`TukeyHSD(x, which, ordered = FALSE, conf.level = 0.95, ...)`

Arguments

- `x` A fitted model object, usually an `aov` fit.
- `which` A character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms.
- `ordered` A logical value indicating if the levels of the factor should be ordered according to increasing average in the sample before taking differences. If `ordered` is true then the calculated differences in the means will all be positive. The significant differences will be those for which the lower end point is positive.
- `conf.level` A numeric value between zero and one giving the family-wise confidence level to use.
- `...` Optional additional arguments. None are used at present.
**Details**

When comparing the means for the levels of a factor in an analysis of variance, a simple comparison using t-tests will inflate the probability of declaring a significant difference when it is not in fact present. This because the intervals are calculated with a given coverage probability for each interval but the interpretation of the coverage is usually with respect to the entire family of intervals.

John Tukey introduced intervals based on the range of the sample means rather than the individual differences. The intervals returned by this function are based on this Studentized range statistics.

The intervals constructed in this way would only apply exactly to balanced designs where there are the same number of observations made at each level of the factor. This function incorporates an adjustment for sample size that produces sensible intervals for mildly unbalanced designs.

If which specifies non-factor terms these will be dropped with a warning: if no terms are left this is an error.

In R 2.15.2 and earlier the results were NA for fits with na.action methods such as `na.exclude`.

**Value**

A list of class `c("multcomp", "TukeyHSD")`, with one component for each term requested in which. Each component is a matrix with columns `diff` giving the difference in the observed means, `lwr` giving the lower end point of the interval, `upr` giving the upper end point and `p adj` giving the p-value after adjustment for the multiple comparisons.

There are print and plot methods for class "TukeyHSD". The plot method does not accept `xlab`, `ylab` or `main` arguments and creates its own values for each plot.

**Author(s)**

Douglas Bates

**References**

**See Also**

`aov, qtukey, model.tables, glht` in package `multcomp`.

**Examples**

```r
require(graphics)

summary(fm1 <- aov(breaks ~ wool + tension, data = warpbreaks))
TukeyHSD(fm1, "tension", ordered = TRUE)
plot(TukeyHSD(fm1, "tension"))
```
Description

These functions provide information about the uniform distribution on the interval from \(\min\) to \(\max\). \(\text{dunif}\) gives the density, \(\text{punif}\) gives the distribution function \(\text{qunif}\) gives the quantile function and \(\text{runif}\) generates random deviates.

Usage

\[
\begin{align*}
\text{dunif}(x, \min = 0, \max = 1, \log = \text{FALSE}) \\
\text{punif}(q, \min = 0, \max = 1, \text{lower.tail} = \text{TRUE}, \log.p = \text{FALSE}) \\
\text{qunif}(p, \min = 0, \max = 1, \text{lower.tail} = \text{TRUE}, \log.p = \text{FALSE}) \\
\text{runif}(n, \min = 0, \max = 1)
\end{align*}
\]

Arguments

- \(x, q\) vector of quantiles.
- \(p\) vector of probabilities.
- \(n\) number of observations. If \(\text{length}(n) > 1\), the length is taken to be the number required.
- \(\min, max\) lower and upper limits of the distribution. Must be finite.
- \(\log, \log.p\) logical; if \(\text{TRUE}\), probabilities \(p\) are given as \(\text{log}(p)\).
- \(\text{lower.tail}\) logical; if \(\text{TRUE}\) (default), probabilities are \(P[X \leq x]\), otherwise, \(P[X > x]\).

Details

If \(\min\) or \(\max\) are not specified they assume the default values of 0 and 1 respectively.

The uniform distribution has density

\[
f(x) = \frac{1}{\max - \min}
\]

for \(\min \leq x \leq \max\).

For the case of \(u := \min == \max\), the limit case of \(X \equiv u\) is assumed, although there is no density in that case and \(\text{dunif}\) will return NaN (the error condition).

\(\text{runif}\) will not generate either of the extreme values unless \(\max = \min\) or \(\max - \min\) is small compared to \(\min\), and in particular not for the default arguments.

Value

\(\text{dunif}\) gives the density, \(\text{punif}\) gives the distribution function, \(\text{qunif}\) gives the quantile function, and \(\text{runif}\) generates random deviates.

The length of the result is determined by \(n\) for \(\text{runif}\), and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \(n\) are recycled to the length of the result. Only the first elements of the logical arguments are used.
Note

The characteristics of output from pseudo-random number generators (such as precision and periodicity) vary widely. See `.Random.seed` for more information on R’s random number generation algorithms.

References

See Also

`RNG` about random number generation in R.

`Distributions` for other standard distributions.

Examples

```r
u <- runif(20)

## The following relations always hold:
punif(u) == u
dunif(u) == 1

var(runif(10000)) # ~ = 1/12 = .08333
```

Description

The function `unirroot` searches the interval from `lower` to `upper` for a root (i.e., zero) of the function `f` with respect to its first argument.

Setting `extendInt` to a non-"no" string, means searching for the correct interval = `c(lower, upper)` if `sign(f(x))` does not satisfy the requirements at the interval end points; see the ‘Details’ section.

Usage

```r
unirroot(f, interval, ..., 
lower = min(interval), upper = max(interval), 
f.lower = f(lower, ...), f.upper = f(upper, ...),
extendInt = c("no", "yes", "downX", "upX"), check.conv = FALSE, 
tol = .Machine$double.eps^0.25, maxiter = 1000, trace = 0)
```

Arguments

- `f` the function for which the root is sought.
- `interval` a vector containing the end-points of the interval to be searched for the root.
- `...` additional named or unnamed arguments to be passed to `f`
- `lower`, `upper` the lower and upper end points of the interval to be searched.
uniroot

1605

f.lower, f.upper
the same as f(upper) and f(lower), respectively. Passing these values from the
caller where they are often known is more economical as soon as f() contains
non-trivial computations.

extendInt
character string specifying if the interval c(lower, upper) should be extended
or directly produce an error when f() does not have differing signs at the end-
points. The default, "no", keeps the search interval and hence produces an error.

check.conv
logical indicating whether a convergence warning of the underlying uniroot
should be caught as an error and if non-convergence in maxiter iterations
should be an error instead of a warning.

tol
the desired accuracy (convergence tolerance).

maxiter
the maximum number of iterations.

trace
integer number; if positive, tracing information is produced. Higher values giv-
ing more details.

Details

Note that arguments after ... must be matched exactly.

Either interval or both lower and upper must be specified: the upper endpoint must be strictly
larger than the lower endpoint. The function values at the endpoints must be of opposite signs (or
zero), for extendInt="no", the default. Otherwise, if extendInt="yes", the interval is extended
on both sides, in search of a sign change, i.e., until the search interval [l, u] satisfies
f(l) · f(u) ≤ 0.

If it is known how f changes sign at the root x₀, that is, if the function is increasing or decreas-
ing there, extendInt can (and typically should) be specified as "upX" (for "upward crossing") or
"downX", respectively. Equivalently, define S := ±1, to require S = sign(f(x₀ + ε)) at the so-
lution. In that case, the search interval [l, u] possibly is extended to be such that S · f(l) ≤ 0 and
S · f(u) ≥ 0.

uniroot() uses Fortran subroutine "zeroin" (from Netlib) based on algorithms given in the
reference below. They assume a continuous function (which then is known to have at least one root
in the interval).

Convergence is declared either if f(x) == 0 or the change in x for one step of the algorithm is less
than tol (plus an allowance for representation error in x).

If the algorithm does not converge in maxiter steps, a warning is printed and the current approxi-
mation is returned.

f will be called as f(x, ... ) for a numeric value of x.

The argument passed to f has special semantics and used to be shared between calls. The function
should not copy it.

Value

A list with at least four components: root and f.root give the location of the root and the value
of the function evaluated at that point. iter and estim.prec give the number of iterations used
and an approximate estimated precision for root. (If the root occurs at one of the endpoints, the
estimated precision is NA.)

Further components may be added in future: component init.it was added in R 3.1.0.

Examples

```r
require(stats) # for str

## some platforms hit zero exactly on the first step:
## if so the estimated precision is 2/3.
fn <- function(x, a) x - a
str(maxmin <- uniroot(fn, c(0, 1), tol = 0.0001, a = 1/3))

## hand held calculator example: fixed point of cos(.):
uniroot(function(x) cos(x) - x, lower = -pi, upper = pi, tol = 1e-9)$root
str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
tol = 0.0001))
str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
tol = 1e-10))

## Find the smallest value x for which exp(x) > 0 (numerically):
r <- uniroot(function(x) 1e80*exp(x) - 1e-300, c(-1000, 0), tol = 1e-15)
str(r, digits.d = 15) # around -745, depending on the platform.

exp(r$root) # = 0, but not for r$root * 0.9999...
minexp <- r$root + (1 - 10*.Machine$double.eps)
exp(minexp) # typically denormalized

### unroot() with new interval extension + checking features: 

```
Update and Re-fit a Model Call

Description

update will update and (by default) re-fit a model. It does this by extracting the call stored in the object, updating the call and (by default) evaluating that call. Sometimes it is useful to call update with only one argument, for example if the data frame has been corrected.

"Extracting the call" in update() and similar functions uses getCall() which itself is a (S3) generic function with a default method that simply gets x$call.

Because of this, update() will often work (via its default method) on new model classes, either automatically, or by providing a simple getCall() method for that class.
Usage

update(object, ...)
## Default S3 method:
update(object, formula., ..., evaluate = TRUE)

getCall(x, ...)

Arguments

object, x An existing fit from a model function such as \texttt{lm}, \texttt{glm} and many others.
formula. Changes to the formula – see \texttt{update.formula} for details.
... Additional arguments to the call, or arguments with changed values. Use name = NULL to remove the argument name.
evaluate If true evaluate the new call else return the call.

Value

If evaluate = \texttt{TRUE} the fitted object, otherwise the updated call.

lm.D9 <- lm(weight ~ group)
lm.D9
summary(lm.D90 <- update(lm.D9, . ~ . - 1))
options(contrasts = c("contr.helmert", "contr.poly"))
update(lm.D9)
getCall(lm.D90) # "through the origin"

options(oldcon)

**Description**

`update.formula` is used to update model formulae. This typically involves adding or dropping terms, but updates can be more general.

**Usage**

```r
## S3 method for class 'formula'
update(old, new, 
```

**Arguments**

- `old` a model formula to be updated.
- `new` a formula giving a template which specifies how to update.
- `...` further arguments passed to or from other methods.

**Details**

Either or both of `old` and `new` can be objects such as length-one character vectors which can be coerced to a formula via `as.formula`.

The function works by first identifying the *left-hand side* and *right-hand side* of the `old` formula. It then examines the `new` formula and substitutes the *lhs* of the `old` formula for any occurrence of `.` on the left of `new`, and substitutes the *rhs* of the `old` formula for any occurrence of `.` on the right of `new`. The result is then simplified via `terms.formula(simplify = TRUE)`.

**Value**

The updated formula is returned. The environment of the result is that of `old`.

**See Also**

`terms, model.matrix`.

**Examples**

```r
update(y ~ x, ~ . + x2) \#> y ~ x + x2
update(y ~ x, log(.) ~ .) \#> log(y) ~ x
```
Description

Performs an F test to compare the variances of two samples from normal populations.

Usage

```r
var.test(x, ...)  
```

```r
# Default S3 method:
var.test(x, y, ratio = 1,  
  alternative = c("two.sided", "less", "greater"),  
  conf.level = 0.95, ...)
```

```r
# S3 method for class 'formula'
var.test(formula, data, subset, na.action, ...)
```

Arguments

- **x, y**: numeric vectors of data values, or fitted linear model objects (inheriting from class "lm").
- **ratio**: the hypothesized ratio of the population variances of `x` and `y`.
- **alternative**: a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
- **conf.level**: confidence level for the returned confidence interval.
- **formula**: a formula of the form `lhs ~ rhs` where `lhs` is a numeric variable giving the data values and `rhs` a factor with two levels giving the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- **...**: further arguments to be passed to or from methods.

Details

The null hypothesis is that the ratio of the variances of the populations from which `x` and `y` were drawn, or in the data to which the linear models `x` and `y` were fitted, is equal to `ratio`.

Value

A list with class "htest" containing the following components:

- **statistic**: the value of the F test statistic.
- **parameter**: the degrees of the freedom of the F distribution of the test statistic.
p.value the p-value of the test.
certainty a confident interval for the ratio of the population variances.
null.value the ratio of the sample variances of \( x \) and \( y \).
null.value the ratio of population variances under the null.
alternative a character string describing the alternative hypothesis.
method the character string "F test to compare two variances".
data.name a character string giving the names of the data.

See Also

bartlett.test for testing homogeneity of variances in more than two samples from normal distributions; ansari.test and mood.test for two rank based (nonparametric) two-sample tests for difference in scale.

Examples

```r
x <- rnorm(50, mean = 0, sd = 2)
y <- rnorm(30, mean = 1, sd = 1)
var.test(x, y)  # Do x and y have the same variance?
var.test(lm(x - 1), lm(y - 1))  # The same.
```

varimix

Rotation Methods for Factor Analysis

Description

These functions ‘rotate’ loading matrices in factor analysis.

Usage

```r
varimax(x, normalize = TRUE, eps = 1e-5)
prmax(x, m = 4)
```

Arguments

- **x** A loadings matrix, with \( p \) rows and \( k < p \) columns
- **m** The power used the target for promax. Values of 2 to 4 are recommended.
- **normalize** logical. Should Kaiser normalization be performed? If so the rows of \( x \) are re-scaled to unit length before rotation, and scaled back afterwards.
- **eps** The tolerance for stopping: the relative change in the sum of singular values.

Details

These seek a ‘rotation’ of the factors \( x \% \% T \) that aims to clarify the structure of the loadings matrix. The matrix \( T \) is a rotation (possibly with reflection) for varimax, but a general linear transformation for promax, with the variance of the factors being preserved.
Value

A list with components

loadings The ‘rotated’ loadings matrix, \(X \times %\) \(R\), of class "loadings".

rotmat The ‘rotation’ matrix.

References

See Also

`factanal`, `Harman74.cor`.

Examples

```r
## varimax with normalize = TRUE is the default
fa <- factanal(~., 2, data = swiss)
varimax(loadings(fa), normalize = FALSE)
promax(loadings(fa))
```

---

**vcov**

*Calculate Variance-Covariance Matrix for a Fitted Model Object*

**Description**

Returns the variance-covariance matrix of the main parameters of a fitted model object.

**Usage**

`vcov(object, ...)`

**Arguments**

- `object` a fitted model object, typically. Sometimes also a `summary()` object of such a fitted model.
- `...` additional arguments for method functions. For the `glm` method this can be used to pass a dispersion parameter.
Weibull

**Details**

This is a generic function. Functions with names beginning in `vcov` will be methods for this function. Classes with methods for this function include: `lm, mlm, glm, nls, summary.lm, summary.glm, negbin, polr, rlm` (in package `MASS`), `multinom` (in package `nnet`), `gls`, `lme` (in package `nlme`), `coxph` and `survreg` (in package `survival`).

`(vcov)` methods for summary objects allow more efficient and still encapsulated access when both `summary(mod)` and `vcov(mod)` are needed.

**Value**

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model. This should have row and column names corresponding to the parameter names given by the `coef` method.

---

**Weibull**

The Weibull Distribution

**Description**

Density, distribution function, quantile function and random generation for the Weibull distribution with parameters shape and scale.

**Usage**

```r
dweibull(x, shape, scale = 1, log = FALSE)
pweibull(q, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
qweibull(p, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
rweibull(n, shape, scale = 1)
```

**Arguments**

- `x, q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `shape, scale` shape and scale parameters, the latter defaulting to 1.
- `log, log.p` logical; if TRUE, probabilities p are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are $P[X ≤ x]$, otherwise, $P[X > x]$.  

**Details**

The Weibull distribution with shape parameter $a$ and scale parameter $\sigma$ has density given by

$$f(x) = (a/\sigma)(x/\sigma)^{a-1}\exp(-(x/\sigma)^a)$$

for $x > 0$. The cumulative distribution function is $F(x) = 1 - \exp(-(x/\sigma)^a)$ on $x > 0$, the mean is $E(X) = \sigma\Gamma(1 + 1/a)$, and the $Var(X) = \sigma^2(\Gamma(1 + 2/a) - (\Gamma(1 + 1/a))^2)$.  

Value

dweibull gives the density, pweibull gives the distribution function, qweibull gives the quantile function, and rweibull generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rweibull, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is

\[-pweibull(t, a, b, lower = \text{FALSE}, \log = \text{TRUE})\]

which is just \( H(t) = (t/b)^a \).

Source

[dpq]weibull are calculated directly from the definitions. rweibull uses inversion.

References

See Also

Distributions for other standard distributions, including the Exponential which is a special case of the Weibull distribution.

Examples

```r
x <- c(0, rlnorm(50))
all.equal(dweibull(x, shape = 1), dexp(x))
all.equal(pweibull(x, shape = 1, scale = pi), pexp(x, rate = 1/pi))
## Cumulative hazard H():
all.equal(pweibull(x, 2.5, pi, lower.tail = \text{FALSE}, \log.p = \text{TRUE}),
-(x/pi)^2.5, tolerance = 1e-15)
all.equal(qweibull(x/11, shape = 1, scale = pi), qexp(x/11, rate = 1/pi))
```

**weighted.mean**

*Weighted Arithmetic Mean*

**Description**

Compute a weighted mean.
Yweighted.mean

Usage

weighted.mean(x, w, ...)

## Default S3 method:
weighted.mean(x, w, ..., na.rm = FALSE)

Arguments

x  an object containing the values whose weighted mean is to be computed.
w  a numerical vector of weights the same length as x giving the weights to use for elements of x.
... arguments to be passed to or from methods.
na.rm a logical value indicating whether NA values in x should be stripped before the computation proceeds.

Details

This is a generic function and methods can be defined for the first argument x: apart from the default methods there are methods for the date-time classes "POSIXct", "POSIXlt", "difftime" and "Date". The default method will work for any numeric-like object for which [, multiplication, division and sum have suitable methods, including complex vectors.

If w is missing then all elements of x are given the same weight, otherwise the weights coerced to numeric by as.numeric and normalized to sum to one (if possible: if their sum is zero or infinite the value is likely to be NaN).

Missing values in w are not handled specially and so give a missing value as the result. However, zero weights are handled specially and the corresponding x values are omitted from the sum.

Value

For the default method, a length-one numeric vector.

See Also

mean

Examples

## GPA from Siegel 1994
wt <- c(5, 5, 4, 1)/15
x <- c(3.7, 3.3, 3.5, 2.8)
xm <- weighted.mean(x, wt)
weighted.residuals  
**Compute Weighted Residuals**

**Description**

Computed weighted residuals from a linear model fit.

**Usage**

```r
weighted.residuals(obj, drop0 = TRUE)
```

**Arguments**

- `obj`: R object, typically of class `lm` or `glm`.
- `drop0`: logical. If `TRUE`, drop all cases with `weights == 0`.

**Details**

Weighted residuals are based on the deviance residuals, which for a `lm` fit are the raw residuals $R_i$ multiplied by $\sqrt{w_i}$, where $w_i$ are the weights as specified in `lm`'s call.

Dropping cases with weights zero is compatible with `influence` and related functions.

**Value**

Numeric vector of length $n'$, where $n'$ is the number of non-0 weights (`drop0 = TRUE`) or the number of observations, otherwise.

**See Also**

`residuals`, `lm.influence`, etc.

**Examples**

```r
## following on from example(lm)

all.equal(weighted.residuals(lm.09), residuals(lm.09))
x <- 1:10
w <- 0:9
y <- rnorm(x)
weighted.residuals(lmxy <- lm(y ~ x, weights = w))
weighted.residuals(lmxy, drop0 = FALSE)
```
weights

**weights**

*Extract Model Weights*

**Description**

weights is a generic function which extracts fitting weights from objects returned by modeling functions.

Methods can make use of `napredict` methods to compensate for the omission of missing values. The default methods does so.

**Usage**

`weights(object, ...)`

**Arguments**

- `object`: an object for which the extraction of model weights is meaningful.
- `...`: other arguments passed to methods.

**Value**

Weights extracted from the object `object`: the default method looks for component "weights" and if not NULL calls `napredict` on it.

**References**

**See Also**

`weights.glm`

wilcox.test

*Wilcoxon Rank Sum and Signed Rank Tests*

**Description**

Performs one- and two-sample Wilcoxon tests on vectors of data; the latter is also known as ‘Mann-Whitney’ test.

**Usage**

`wilcox.test(x, ...)`

## Default S3 method:

```r
wilcox.test(x, y = NULL, 
  alternative = c("two.sided", "less", "greater"), 
  mu = 0, paired = FALSE, exact = NULL, correct = TRUE, 
  conf.int = FALSE, conf.level = 0.95, ...)
```

## S3 method for class 'formula'

```r
wilcox.test(formula, data, subset, na.action, ...)
```
Arguments

- **x**: numeric vector of data values. Non-finite (e.g., infinite or missing) values will be omitted.
- **y**: an optional numeric vector of data values: as with x non-finite values will be omitted.
- **alternative**: a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
- **mu**: a number specifying an optional parameter used to form the null hypothesis. See 'Details'.
- **paired**: a logical indicating whether you want a paired test.
- **exact**: a logical indicating whether an exact p-value should be computed.
- **correct**: a logical indicating whether to apply continuity correction in the normal approximation for the p-value.
- **conf.int**: a logical indicating whether a confidence interval should be computed.
- **conf.level**: confidence level of the interval.
- **formula**: a formula of the form `lhs ~ rhs` where `lhs` is a numeric variable giving the data values and `rhs` a factor with two levels giving the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- **...**: further arguments to be passed to or from methods.

Details

The formula interface is only applicable for the 2-sample tests.

If only x is given, or if both x and y are given and `paired` is TRUE, a Wilcoxon signed rank test of the null that the distribution of x (in the one sample case) or of x ~ y (in the paired two sample case) is symmetric about `mu` is performed.

Otherwise, if both x and y are given and `paired` is FALSE, a Wilcoxon rank sum test (equivalent to the Mann-Whitney test: see the Note) is carried out. In this case, the null hypothesis is that the distributions of x and y differ by a location shift of `mu` and the alternative is that they differ by some other location shift (and the one-sided alternative "greater" is that x is shifted to the right of y).

By default (if `exact` is not specified), an exact p-value is computed if the samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

 Optionally (if argument `conf.int` is true), a nonparametric confidence interval and an estimator for the pseudomedian (one-sample case) or for the difference of the location parameters x-y is computed. (The pseudomedian of a distribution $F$ is the median of the distribution of $(u + v)/2$, where $u$ and $v$ are independent, each with distribution $F$. If $F$ is symmetric, then the pseudomedian and median coincide. See Hollander & Wolfe (1973), page 34.) Note that in the two-sample case the estimator for the difference in location parameters does not estimate the difference in medians (a common misconception) but rather the median of the difference between a sample from x and a sample from y.
If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations. These are continuity-corrected for the interval but not the estimate (as the correction depends on the alternative).

With small samples it may not be possible to achieve very high confidence interval coverages. If this happens a warning will be given and an interval with lower coverage will be substituted.

Value

A list with class "htest" containing the following components:

- statistic: the value of the test statistic with a name describing it.
- parameter: the parameter(s) for the exact distribution of the test statistic.
- p.value: the p-value for the test.
- null.value: the location parameter mu.
- alternative: a character string describing the alternative hypothesis.
- method: the type of test applied.
- data.name: a character string giving the names of the data.
- conf.int: a confidence interval for the location parameter. (Only present if argument conf.int = TRUE.)
- estimate: an estimate of the location parameter. (Only present if argument conf.int = TRUE.)

Warning

This function can use large amounts of memory and stack (and even crash R if the stack limit is exceeded) if exact = TRUE and one sample is large (several thousands or more).

Note

The literature is not unanimous about the definitions of the Wilcoxon rank sum and Mann-Whitney tests. The two most common definitions correspond to the sum of the ranks of the first sample with the minimum value subtracted or not: R subtracts and S-PLUS does not, giving a value which is larger by \( m(m+1)/2 \) for a first sample of size \( m \). (It seems Wilcoxon’s original paper used the unadjusted sum of the ranks but subsequent tables subtracted the minimum.)

R’s value can also be computed as the number of all pairs \((x[i], y[j])\) for which \(y[j]\) is not greater than \(x[i]\), the most common definition of the Mann-Whitney test.

---

**Distribution of the Wilcoxon Rank Sum Statistic**

**Description**

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon rank sum statistic obtained from samples with size \( m \) and \( n \), respectively.
Arguments

- `x`, `q` vector of quantiles.
- `p` vector of probabilities.
- `nn` number of observations. If `length(nn) > 1`, the length is taken to be the number required.
- `m`, `n` numbers of observations in the first and second sample, respectively. Can be vectors of positive integers.
- `log`, `log.p` logical; if TRUE, probabilities `p` are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

This distribution is obtained as follows. Let $x$ and $y$ be two random, independent samples of size $m$ and $n$. Then the Wilcoxon rank sum statistic is the number of all pairs $(x[i], y[j])$ for which $y[j]$ is not greater than $x[i]$. This statistic takes values between 0 and $m \cdot n$, and its mean and variance are $m \cdot n / 2$ and $m \cdot n \cdot (m + n + 1) / 12$, respectively.

If any of the first three arguments are vectors, the recycling rule is used to do the calculations for all combinations of the three up to the length of the longest vector.

Value

dwilcox gives the density, pwilcox gives the distribution function, qwilcox gives the quantile function, and rwilcox generates random deviates.

The length of the result is determined by `nn` for `rwilcox`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `nn` are recycled to the length of the result. Only the first elements of the logical arguments are used.

Warning

These functions can use large amounts of memory and stack (and even crash R if the stack limit is exceeded and stack-checking is not in place) if one sample is large (several thousands or more).

Note

S-PLUS uses a different (but equivalent) definition of the Wilcoxon statistic: see `wilcox.test` for details.

Author(s)

Kurt Hornik
Source

These are calculated via recursion, based on \( c_{\text{wilcox}}(k, m, n) \), the number of choices with statistic \( k \) from samples of size \( m \) and \( n \), which is itself calculated recursively and the results cached. Then \( d_{\text{wilcox}} \) and \( p_{\text{wilcox}} \) sum appropriate values of \( c_{\text{wilcox}} \), and \( q_{\text{wilcox}} \) is based on inversion. \( r_{\text{wilcox}} \) generates a random permutation of ranks and evaluates the statistic.

See Also

\texttt{wilcox.test} to calculate the statistic from data, find \( p \) values and so on.

Distributions for standard distributions, including \texttt{dsignrank} for the distribution of the one-sample Wilcoxon signed rank statistic.

Examples

```r
require(graphics)
x <- -1:(4*6 + 1)
fx <- dwilcox(x, 4, 6)
Fx <- pwilcox(x, 4, 6)

layout(rbind(1,2), widths = 1, heights = c(3, 2))
plot(x, fx, type = "h", col = "violet",
     main = "Probabilities (density) of Wilcoxon-Statistic.\(n=6, m=4\)"
     plot(x, Fx, type = "s", col = "blue",
     main = "Distribution of Wilcoxon-Statistic.\(n=6, m=4\)"
abline(h = 0:1, col = "gray20", lty = 2)
layout(1) # set back

N <- 200
hist(U <- rwilcox(N, m = 4, n = 6), breaks = 0:25 - 1/2,
    border = "red", col = "pink", sub = paste("N =",N))
mtext("N * f(x), f() = true \"density\"", side = 3, col = "blue")
lines(x, N+fx, type = "h", col = "blue", lwd = 2)
points(x, N+fx, cex = 2)

## Better is a Quantile-Quantile Plot
qqplot(U, qw <- qwilcox((1:N - 1/2)/N, m = 4, n = 6),
     main = paste("Q-Q-Plot of empirical and theoretical quantiles",
     "Wilcoxon Statistic, (m=4, n=6)", sep = "\n")
n <- as.numeric(names(print(tU <- table(U)))))
text(n+.2, n+.5, labels = tU, col = "red")
```

Description

\texttt{window} is a generic function which extracts the subset of the object \( x \) observed between the times \texttt{start} and \texttt{end}. If a frequency is specified, the series is then re-sampled at the new frequency.
Usage

```r
window(x, ...)  
## S3 method for class 'ts'
window(x, ...)  
## Default S3 method:
window(x, start = NULL, end = NULL,
       frequency = NULL, deltat = NULL, extend = FALSE, ...)

window(x, ...) <- value  
## S3 replacement method for class 'ts'
window(x, start, end, frequency, deltat, ...) <- value
```

Arguments

- **x**: a time-series (or other object if not replacing values).
- **start**: the start time of the period of interest.
- **end**: the end time of the period of interest.
- **frequency, deltat**: the new frequency can be specified by either (or both if they are consistent).
- **extend**: logical. If true, the `start` and `end` values are allowed to extend the series. If false, attempts to extend the series give a warning and are ignored.
- **...**: further arguments passed to or from other methods.
- **value**: replacement values.

Details

The start and end times can be specified as for `ts`. If there is no observation at the new `start` or `end`, the immediately following (`start`) or preceding (`end`) observation time is used.

The replacement function has a method for `ts` objects, and is allowed to extend the series (with a warning). There is no default method.

Value

The value depends on the method. `window.default` will return a vector or matrix with an appropriate `tsp` attribute.

`window.ts` differs from `window.default` only in ensuring the result is a `ts` object.

If `extend = TRUE` the series will be padded with NAs if needed.

window(presidents, start = c(1945,3), deltat = 1)  # All Qtr3s
window(presidents, 1944, c(1979,2), extend = TRUE)

pres <- window(presidents, 1945, c(1949,4))  # values in the 1940's
window(pres, 1945.25, 1945.50) <- c(50, 70)
window(pres, 1944, 1944.75) <- 0 # will generate a warning
window(pres, c(1945,4), c(1949,4), frequency = 1) <- 85:89
pres
```

xtabs  

Cross Tabulation

Description

Create a contingency table (optionally a sparse matrix) from cross-classifying factors, usually contained in a data frame, using a formula interface.

Usage

```r
xtabs(formula = ~., data = parent.frame(), subset, sparse = FALSE, na.action, exclude = c(NA, NaN), drop.unused.levels = FALSE)
```

Arguments

- `formula`: a formula object with the cross-classifying variables (separated by +) on the right hand side (or an object which can be coerced to a formula). Interactions are not allowed. On the left hand side, one may optionally give a vector or a matrix of counts; in the latter case, the columns are interpreted as corresponding to the levels of a variable. This is useful if the data have already been tabulated, see the examples below.

- `data`: an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.

- `subset`: an optional vector specifying a subset of observations to be used.

- `sparse`: logical specifying if the result should be a sparse matrix, i.e., inheriting from `sparseMatrix`. Only works for two factors (since there are no higher-order sparse array classes yet).

- `na.action`: a function which indicates what should happen when the data contain NAs.

- `exclude`: a vector of values to be excluded when forming the set of levels of the classifying factors.

- `drop.unused.levels`: a logical indicating whether to drop unused levels in the classifying factors. If this is `FALSE` and there are unused levels, the table will contain zero marginals, and a subsequent chi-squared test for independence of the factors will not work.
Details

There is a summary method for contingency table objects created by `table` or `xtabs(*, sparse = FALSE)`, which gives basic information and performs a chi-squared test for independence of factors (note that the function `chisq.test` currently only handles 2-d tables).

If a left hand side is given in `formula`, its entries are simply summed over the cells corresponding to the right hand side; this also works if the lhs does not give counts.

For variables in `formula` which are factors, `exclude` must be specified explicitly; the default exclusions will not be used.

Value

By default, when `sparse = FALSE`, a contingency table in array representation of S3 class `c(“xtabs”, “table”), with a “call” attribute storing the matched call.

When `sparse = TRUE`, a sparse numeric matrix, specifically an object of S4 class `dgTMatrix` from package `Matrix`.

See Also

`table` for traditional cross-tabulation, and `as.data.frame.table` which is the inverse operation of `xtabs` (see the DF example below).

`sparseMatrix` on sparse matrices in package `Matrix`.

Examples

```r
## 'esoph' has the frequencies of cases and controls for all levels of
## the variables 'agegp', 'alcgp', and 'tobgp'.
xtabs(cbind(ncases, ncontrols) ~ ., data = esoph)
## Output is not really helpful ... flat tables are better:
ftable(xtabs(cbind(ncases, ncontrols) ~ ., data = esoph))
## In particular if we have fewer factors ...
ftable(xtabs(cbind(ncases, ncontrols) ~ agegp, data = esoph))

## This is already a contingency table in array form.
DF <- as.data.frame(UCBAdmissions)
## Now 'DF' is a data frame with a grid of the factors and the counts
## in variable 'Freq'.
DF
## Nice for taking margins ...
xtabs(Freq ~ Gender + Admit, DF)
## And for testing independence ...
summary(xtabs(Freq ~ ., DF))

## Create a nice display for the warp break data.
warpbreaks$replicate <- rep(1:9, len = 54)
ftable(xtabs(breaks ~ wool + tension + replicate, data = warpbreaks))

### ---- Sparse Examples ----

if(require("Matrix")) {
## similar to "nlme"s 'ergoStool' :
d.ergo <- data.frame(Type = paste0("T", rep(1:4, 9*4)),
                     Subj = gl(9, 4, 36*4))
print(xtabs(~ Type + Subj, data = d.ergo)) # 4 replicates each
}```
set.seed(15) # a subset of cases:
print(xtabs(~ Type + Subj, data = d.ergo[sample(36, 10), ], sparse = TRUE))

## Hypothetical two level setup:
inner <- factor(sample(letters[1:25], 100, replace = TRUE))
inout <- factor(sample(LETTERS[1:5], 25, replace = TRUE))
fr <- data.frame(inner = inner, outer = inout[as.integer(inner)])
print(xtabs(~ inner + outer, fr, sparse = TRUE))
}
Chapter 11

The stats4 package

---

**Description**

Statistical Functions using S4 classes.

**Details**

This package contains functions and classes for statistics using the S version 4 class system. The methods currently support maximum likelihood (function `mle()` returning class "mle"), including methods for `logLik` for use with `AIC`.

**Author(s)**

R Core Team and contributors worldwide

Maintainer: R Core Team <R-core@r-project.org>

---

**Methods for Function coef in Package stats4**

**Description**

Extract the coefficient vector from "mle" objects.

**Methods**

- `signature(object = "ANY")` Generic function: see `coef`.
- `signature(object = "mle")` Extract the full coefficient vector (including any fixed coefficients) from the fit.
- `signature(object = "summary.mle")` Extract the coefficient vector and standard errors from the summary of the fit.
confint-methods  Methods for Function confint in Package stats4

Description
Generate confidence intervals

Methods
signature(object = "ANY") Generic function: see confint.
signature(object = "mle") First generate profile and then confidence intervals from the profile.
signature(object = "profile.mle") Generate confidence intervals based on likelihood profile.

logLik-methods  Methods for Function logLik in Package stats4

Description
Extract the maximized log-likelihood from "mle" objects.

Methods
signature(object = "ANY") Generic function: see logLik.
signature(object = "mle") Extract log-likelihood from the fit.

Note
The mle method does not know about the number of observations unless nobs was specified on the call and so may not be suitable for use with BIC.

mle  Maximum Likelihood Estimation

Description
Estimate parameters by the method of maximum likelihood.

Usage
mle(minuslogl, start = formals(minuslogl), method = "BFGS",
fixed = list(), nobs, ...)
Arguments

minuslogl  Function to calculate negative log-likelihood.
start     Named list. Initial values for optimizer.
method    Optimization method to use. See optim.
fixed     Named list. Parameter values to keep fixed during optimization.
nobs      optional integer: the number of observations, to be used for e.g. computing BIC.
...       Further arguments to pass to optim.

Details

The optim optimizer is used to find the minimum of the negative log-likelihood. An approximate covariance matrix for the parameters is obtained by inverting the Hessian matrix at the optimum.

Value

An object of class mle-class.

Note

Be careful to note that the argument is -log L (not -2 log L). It is for the user to ensure that the likelihood is correct, and that asymptotic likelihood inference is valid.

See Also

mle-class

Examples

### Avoid printing to unwarranted accuracy

od <- options(digits = 5)
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)

### Easy one-dimensional MLE:

nL <- function(lambda) -sum(stats::dpois(y, lambda, log = TRUE))
fit0 <- mle(nL, start = list(lambda = 5), nobs = NROW(y))
# For R, this is preferable:
fit1 <- mle(nL, start = list(lambda = 5), nobs = NROW(y),
            method = "Brent", lower = 1, upper = 20)
stopifnot(nobs(fit0) == length(y))

### This needs a constrained parameter space: most methods will accept NA

l1 <- function(ymax = 15, xhalf = 6) {
  if(ymax > 0 && xhalf > 0) -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
  else NA
}
(fit <- mle(l1, nobs = length(y)))
mle(l1, fixed = list(xhalf = 6))

### alternative using bounds on optimization

l12 <- function(ymax = 15, xhalf = 6)
  -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
mle(l12, method = "L-BFGS-B", lower = rep(0, 2))
AIC(fit)
BIC(fit)

summary(fit)
logLik(fit)
vcof(fit)
plot(profile(fit), absVal = FALSE)
confint(fit)

## Use bounded optimization
## The lower bounds are really > 0.
## but we use >=@ to stress-test profiling
(fit2 <- mle(ll, method = "L-BFGS-B", lower = c(0, 0)))
plot(profile(fit2), absVal = FALSE)

## a better parametrization:
ll3 <- function(lymax = log(15), lxhalf = log(6))
  -sum(stats::dpois(y, lambda = exp(lymax)/(1+x/exp(lxhalf)), log = TRUE))
(fit3 <- mle(ll3))
plot(profile(fit3), absVal = FALSE)
exp(confint(fit3))

options(od)

---

mle-class  
Class "mle" for Results of Maximum Likelihood Estimation

Description

This class encapsulates results of a generic maximum likelihood procedure.

Objects from the Class

Objects can be created by calls of the form new("mle", ...), but most often as the result of a call to mle.

Slots

call: Object of class "language". The call to mle.
coef: Object of class "numeric". Estimated parameters.
fullcoef: Object of class "numeric". Fixed and estimated parameters.
vcof: Object of class "matrix". Approximate variance-covariance matrix.
min: Object of class "numeric". Minimum value of objective function.
details: a "list", as returned from optim.
minuslogl: Object of class "function". The negative loglikelihood function.
nobs: "integer" of length one. The number of observations (often NA, when not set in call explicitly).
method: Object of class "character". The optimization method used.
Methods

confint signature(object = "mle"): Confidence intervals from likelihood profiles.
logLik signature(object = "mle"): Extract maximized log-likelihood.
profile signature(fitted = "mle"): Likelihood profile generation.
nobs signature(object = "mle"): Number of observations, here simply accessing the nobs slot mentioned above.
show signature(object = "mle"): Display object briefly.
summary signature(object = "mle"): Generate object summary.
update signature(object = "mle"): Update fit.
vcov signature(object = "mle"): Extract variance-covariance matrix.

plot-methods

Methods for Function plot in Package stats4

Description

Plot profile likelihoods for "mle" objects.

Usage

## S4 method for signature 'profile.mle,missing'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100, nseg = 50,
     absVal = TRUE, ...)

Arguments

x an object of class "profile.mle"
levels levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually conf is used instead of giving levels explicitly.
conf a numeric vector of confidence levels for profile-based confidence intervals on the parameters.
nseg an integer value giving the number of segments to use in the spline interpolation of the profile t curves.
absVal a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to TRUE.
... other arguments to the plot function can be passed here.

Methods

signature(x = "ANY", y = "ANY") Generic function: see plot.
signature(x = "profile.mle", y = "missing") Plot likelihood profiles for x.
Description

Profile likelihood for "mle" objects.

Usage

```r
## S4 method for signature 'mle'
profile(fitted, which = 1:p, maxsteps = 100, alpha = 0.01,
        zmax = sqrt(qchisq(1 - alpha, 1L)), del = zmax/5,
        trace = FALSE, ...)
```

Arguments

- `fitted`: Object to be profiled
- `which`: Optionally select subset of parameters to profile.
- `maxsteps`: Maximum number of steps to bracket `zmax`.
- `alpha`: Significance level corresponding to `zmax`, based on a Scheffe-style multiple testing interval. Ignored if `zmax` is specified.
- `zmax`: Cutoff for the profiled value of the signed root-likelihood.
- `del`: Initial stepsize on root-likelihood scale.
- `trace`: Logical. Print intermediate results.
- `...`: Currently unused.

Details

The profiling algorithm tries to find an approximately evenly spaced set of at least five parameter values (in each direction from the optimum) to cover the root-likelihood function. Some care is taken to try and get sensible results in cases of high parameter curvature. Notice that it may not always be possible to obtain the cutoff value, since the likelihood might level off.

Value

An object of class "profile.mle", see "profile.mle-class".

Methods

```r
signature(fitted = "ANY") Generic function: see profile.
signature(fitted = "mle") Profile the likelihood in the vicinity of the optimum of an "mle" object.
```
profile.mle-class

Description

Likelihood profiles along each parameter of likelihood function

Objects from the Class

Objects can be created by calls of the form `new("profile.mle", ...), but most often by invoking `profile` on an "mle" object.

Slots

profile: Object of class "list". List of profiles, one for each requested parameter. Each profile is a data frame with the first column called `z` being the signed square root of the -2 log likelihood ratio, and the others being the parameters with names prefixed by `par.NvaNs`.

summary: Object of class "summary.mle". Summary of object being profiled.

Methods

`confint` signature(object = "profile.mle"): Use profile to generate approximate confidence intervals for parameters.

`plot` signature(x = "profile.mle", y = "missing"): Plot profiles for each parameter.

See Also

`mle, mle-class, summary.mle-class`

show-methods

Methods for Function `show` in Package `stats4`

Description

Show objects of classes `mle` and `summary.mle`

Methods

`signature(object = "mle")` Print simple summary of `mle` object. Just the coefficients and the call.

`signature(object = "summary.mle")` Shows call, table of coefficients and standard errors, and $-2 \log L$. 
Summary methods

Methods for Function summary in Package stats4

Description

Summarize objects

Methods

signature(object = "ANY") Generic function

signature(object = "mle") Generate a summary as an object of class "summary.mle", containing estimates, asymptotic SE, and value of $-2 \log L$.

summary.mle-class

Class "summary.mle", Summary of "mle" Objects

Description

Extract of "mle" object

Objects from the Class

Objects can be created by calls of the form `new("summary.mle", ...)`, but most often by invoking `summary` on an "mle" object. They contain values meant for printing by `show`.

Slots

call: Object of class "language" The call that generated the "mle" object.
coef: Object of class "matrix". Estimated coefficients and standard errors

m2logL: Object of class "numeric". Minus twice the log likelihood.

Methods

show signature(object = "summary.mle"): Pretty-prints object

coef signature(object = "summary.mle"): Extracts the contents of the coef slot

See Also

summary.mle, mle-class
**Description**

Update "mle" objects.

**Usage**

```r
## S4 method for signature 'mle'
update(object, ..., evaluate = TRUE)
```

**Arguments**

- `object`: An existing fit.
- `...`: Additional arguments to the call, or arguments with changed values. Use `name = NULL` to remove the argument name.
- `evaluate`: If true evaluate the new call else return the call.

**Methods**

- `signature(object = "ANY")` Generic function: see `update`.
- `signature(object = "mle")` Update a fit.

**Examples**

```r
x <- 0:10
y <- c(26, 17, 13, 20, 5, 9, 8, 5, 4, 8)
l1 <- function(ymax = 15, xhalf = 6)
    -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
fit <- mle(l1)
## note the recorded call contains ..l, a problem with S4 dispatch
update(fit, fixed = list(xhalf = 3))
```

---

**vcov-methods**

**Methods for Function vcov in Package stats4**

**Description**

Extract the approximate variance-covariance matrix from "mle" objects.

**Methods**

- `signature(object = "ANY")` Generic function: see `vcov`.
- `signature(object = "mle")` Extract the estimated variance-covariance matrix for the estimated parameters (if any).
Chapter 12

The tcltk package

---

**tcltk-package**  
**Tcl/Tk Interface**

**Description**

Interface and language bindings to Tcl/Tk GUI elements.

**Details**

This package provides access to the platform-independent Tcl scripting language and Tk GUI elements. See TkWidgets for a list of supported widgets, TkWidgetcmds for commands to work with them, and references in those files for more.

The Tcl/Tk documentation is in the system man pages.

For a complete list of functions, use ls("package:tcltk").

Note that Tk will not be initialized if there is no DISPLAY variable set, but Tcl can still be used. This is most useful to allow the loading of a package which depends on tcltk in a session that does not actually use it (e.g., during installation).

**Author(s)**

---

**TclInterface**  
**Low-level Tcl/Tk Interface**

**Description**

These functions and variables provide the basic glue between R and the Tcl interpreter and Tk GUI toolkit. Tk windows may be represented via R objects. Tcl variables can be accessed via objects of class tclVar and the C level interface to Tcl objects is accessed via objects of class tclObj.
Usage

.Tcl(...)  
.Tcl.objv(objv)  
.Tcl.args(...)  
.Tcl.args.objv(...)  
.Tcl.callback(...)  
.Tk.ID(win)  
.Tk.newwin(ID)  
.Tk.subwin(parent)  
.TkRoot

tkdestroy(win)  
is.tkwin(x)

tclvalue(x)  
tclvalue(x) <- value

tclVar(init = "")  
## S3 method for class 'tclVar'  
as.character(x, ...)  
## S3 method for class 'tclVar'  
tclvalue(x)  
## S3 replacement method for class 'tclVar'  
tclvalue(x) <- value

tclArray()  
## S3 method for class 'tclArray'  
x[[...]]  
## S3 replacement method for class 'tclArray'  
x[[...]] <- value  
## S3 method for class 'tclArray'  
x$i  
## S3 replacement method for class 'tclArray'  
x$i <- value

## S3 method for class 'tclArray'  
names(x)  
## S3 method for class 'tclArray'  
length(x)

tclObj(x)  
tclObj(x) <- value  
## S3 method for class 'tclVar'  
tclObj(x)  
## S3 replacement method for class 'tclVar'  
tclObj(x) <- value

as.tclObj(x, drop = FALSE)  
is.tclObj(x)

## S3 method for class 'tclObj'  
as.character(x, ...)
## TclInterface

```r
## S3 method for class 'tclObj'
as.integer(x, ...)
## S3 method for class 'tclObj'
as.double(x, ...)
## S3 method for class 'tclObj'
as.logical(x, ...)
## S3 method for class 'tclObj'
as.raw(x, ...)
## S3 method for class 'tclObj'
tclvalue(x)

## Default S3 method:
tclvalue(x)
## Default S3 replacement method:
tclvalue(x) <- value

addTclPath(path = ".")
tclRequire(package, warn = TRUE)
```

### Arguments

- `objv`  
  A named vector of Tcl objects
- `win`  
  A window structure
- `x`  
  An object
- `i`  
  Character or (unquoted) name
- `drop`  
  Logical. Indicates whether a single-element vector should be made into a simple Tcl object or a list of length one
- `value`  
  For `tclvalue` assignments, a character string. For `tclObj` assignments, an object of class `tclObj`
- `ID`  
  A window ID
- `parent`  
  A window which becomes the parent of the resulting window
- `path`  
  Path to a directory containing Tcl packages
- `package`  
  A Tcl package name
- `warn`  
  Logical. Warn if not found?
- `...`  
  Additional arguments. See below.
- `init`  
  Initialization value

### Details

Many of these functions are not intended for general use but are used internally by the commands that create and manipulate Tk widgets and Tcl objects. At the lowest level, Tcl sends a command as a text string to the Tcl interpreter and returns the result as an object of class `tclObj` (see below). A newer variant `Tcl.objv` accepts arguments in the form of a named list of `tclObj` objects.

`.Tcl.args` converts an R argument list of `tag = value` pairs to the Tcl `option value` style, thus enabling a simple translation between the two languages. To send a value with no preceding option flag to Tcl, just use an untagged argument. In the rare case one needs an option with no subsequent value `tag = NULL` can be used. Most values are just converted to character mode and inserted in
TclInterface

the command string, but window objects are passed using their ID string, and callbacks are passed
via the result of .Tcl.callback. Tags are converted to option flags simply by prepending a -
.Tcl.args.objv serves a similar purpose as .Tcl.args but produces a list of tclobj objects
suitable for passing to .Tcl.objv. The names of the list are converted to Tcl option style internally
by .Tcl.objv.

Callbacks can be either atomic callbacks handled by .Tcl.callback or expressions. An expression
is treated as a list of atomic callbacks, with the following exceptions: if an element is a name, it
is first evaluated in the callers frame, and likewise if it is an explicit function definition; the break
expression is translated directly to the Tcl counterpart. .Tcl.callback converts R functions and
unevaluated calls to Tcl command strings. The argument must be either a function closure or an
object of mode "call" followed by an environment. The return value in the first case is of the
form R_call 0x408b94d4 in which the hexadecimal number is the memory address of the
function. In the second case it will be of the form R_call Lang 0x8a950904 0x819bf60. For
expressions, a sequence of similar items is generated, separated by semicolons. .Tcl.args takes
special precautions to ensure that functions or calls will continue to exist at the specified address by
assigning the callback into the relevant window environment (see below).

Tk windows are represented as objects of class tkwin which are lists containing a ID field and an
env field which is an R environments, enclosed in the global environment. The value of the ID
field is identical to the Tk window name. The env environment contains a parent variable and a
num_subwin variable. If the window obtains sub-windows and callbacks, they are added as variables
to the environment. .TkRoot is the top window with ID "."; this window is not displayed in order
to avoid ill effects of closing it via window manager controls. The parent variable is undefined for
.TkRoot.

.Tk.ID extracts the ID of a window, .Tk.newwin creates a new window environment with a given
ID and .Tk.subwin creates a new window which is a sub-window of a given parent window.

.tkdestroy destroys a window and also removes the reference to a window from its parent.

is.tkwin can be used to test whether a given object is a window environment.

tclVar creates a new Tcl variable and initializes it to init. An R object of class tclVar is created
to represent it. Using as.character on the object returns the Tcl variable name. Accessing the Tcl
variable from R is done using the tclvalue function, which can also occur on the left-hand side of
assignments. If tclvalue is passed an argument which is not a tclVar object, then it will assume
that it is a character string explicitly naming global Tcl variable. Tcl variables created by tclVar
are uniquely named and automatically unset by the garbage collector when the representing object
is no longer in use.

tclArray creates a new Tcl array and initializes it to the empty array. An R object of class tclArray
and inheriting from class tclVar is created to represent it. You can access elements of the Tcl
array using indexing with [[ or $, which also allow replacement forms. Notice that Tcl arrays are
associative by nature and hence unordered; indexing with a numeric index i refers to the element
with the name as.character(i). Multiple indices are pasted together separated by commas to
form a single name. You can query the length and the set of names in an array using methods for
length and names, respectively; these cannot meaningfully be set so assignment forms exist only
to print an error message.

It is possible to access Tcl’s ‘dual-ported’ objects directly, thus avoiding parsing and deparsing of
their string representation. This works by using objects of class tclobj. The string representation
of such objects can be extracted (but not set) using tclvalue and conversion to vectors of mode
"character", "double", "integer", "logical", and "raw" is performed using the standard co-
ercion functions as.character, etc. Conversely, such vectors can be converted using as.tclobj.
There is an ambiguity as to what should happen for length one vectors, controlled by the drop
argument; there are cases where the distinction matters to Tcl, although mostly it treats them equi-

has embedded spaces, the former is sometimes to be preferred, in particular when applied to the
result of tclread, tkgetopenfile, and similar functions. The as.raw method returns a raw vector
or a list of raw vectors and can be used to return binary data from Tcl.

The object behind a tclVar object is extracted using tclObj(x) which also allows an assignment
form, in which the right hand side of the assignment is automatically converted using as.tclObj.
There is a print method for tclObj objects; it prints <Tcl> followed by the string representation
of the object. Notice that as.character on a tclVar object is the name of the corresponding Tcl
variable and not the value.

Tcl packages can be loaded with tclRequire; it may be necessary to add the directory where they
are found to the Tcl search path with addTclPath. The return value is a class "tclObj" object if
it succeeds, or FALSE if it fails (when a warning is issued). To see the current search path as an R
character vector, use

```r
strsplit(tclvalue('auto_path'), " ")[1]
```

Note

Strings containing unbalanced braces are currently not handled well in many circumstances.

TkWidgets, TkCommands, TkWidgetcmds.

capabilities("tcltk") to see if Tcl/Tk support was compiled into this build of R.

Examples

```r
## Not run:
## These cannot be run by example() but should be OK when pasted
## into an interactive R session with the tcltk package loaded
.Tcl("format %s\n" "Hello, World!"")
f <- function(){cat("Hi!\n")
.Tcl.callback(f)
.Tcl.args(text = "Push!", command = f) # NB: Different address

xyzzy <- tclVar(7913)
tclvalue(xyzzy)
tclvalue(xyzzy) <- "foo"
as.character(xyzzy)
tcl("set", as.character(xyzzy))

top <- tktoplevel() # a Tk widget, see Tk-widgets
ls(envir = top$env, all = TRUE)
ls(envir = .TkRoot$env, all = TRUE) # .Tcl.args put a callback ref in here

## End(Not run)
```
tkServiceMode  

**Description**

This function controls or reports on the Tcl service mode, i.e., whether Tcl will respond to events.

**Usage**

tkServiceMode(on = NULL)

**Arguments**

- on  
  (logical) Whether event servicing is turned on.

**Details**

If called with on == NULL (the default), no change is made.

Note that this blocks all Tcl/Tk activity, including for widgets from other packages. It may be better to manage mapping of windows individually.

**Value**

The value of the Tcl service mode before the call.

**Examples**

```python
oldmode <- tkServiceMode(FALSE)
# Do some work to create a nice picture.
# Nothing will be displayed until...
tkServiceMode(oldmode)

## End(Not run)
## another idea is to use tkwm.withdraw() ... tkwm.deiconify()
```

---

**TkCommands**

**Tk non-widget commands**

**Description**

These functions interface to Tk non-widget commands, such as the window manager interface commands and the geometry managers.
Usage

tcl(...)  
tktitle(x)

 tkttitle(x) <- value

tkbell(...)  
tkbind(...)

Arguments

x A window object
value For tkttitle assignments, a character string.
... Handled via .Tcl.args

Details
tcl provides a generic interface to calling any Tk or Tcl command by simply running .Tcl.args.objv on the argument list and passing the result to .Tcl.objv. Most of the other commands simply call tcl with a particular first argument and sometimes also a second argument giving the subcommand.
tkttitle and its assignment form provides an alternate interface to Tk's wm title
There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. With a few exceptions, the pattern is that Tk subcommands like pack configure are converted to function names like tkpack.configure, and Tcl subcommands are like tclfile.dir.

TclInterface, TkWidgets, TkWidgetcmds
tkpager

Page file using Tk text widget

Description

This plugs into file.show, showing files in separate windows.

Usage

```
tkpager(file, header, title, delete.file)
```

Arguments

- **file**: character vector containing the names of the files to be displayed
- **header**: headers to use for each file
- **title**: common title to use for the window(s). Pasted together with the header to form actual window title.
- **delete.file**: logical. Should file(s) be deleted after display?

Note

The "\b.." string used for underlining is currently quietly removed. The font and background colour are currently hardcoded to Courier and gray90.

See Also

```
file.show
```
tkProgressBar

Progress Bars via Tk

Description
Put up a Tk progress bar widget.

Usage

```r
tkProgressBar(title = "R progress bar", label = "",
               min = 0, max = 1, initial = 0, width = 300)

getTkProgressBar(pb)
setTkProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'tkProgressBar'
close(con, ...)
```

Arguments

- `title, label` character strings, giving the window title and the label on the dialog box respectively.
- `min, max` (finite) numeric values for the extremes of the progress bar.
- `initial, value` initial or new value for the progress bar.
- `width` the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame).
- `pb, con` an object of class "tkProgressBar".
- `...` for consistency with the generic.

Details

tkProgressBar will display a widget containing a label and progress bar.
setTkProgressBar will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of value will be (silently) ignored.

The progress bar should be closed when finished with.

This will use the ttk::progressbar widget for Tk version 8.5 or later, otherwise R's copy of BWidget's progressbar.

Value

- For `tkProgressBar` an object of class "tkProgressBar".
- For `getTkProgressBar` and `setTkProgressBar`, a length-one numeric vector giving the previous value (invisibly for `setTkProgressBar`).

See Also

txtProgressBar
Examples

pb <- tkProgressBar("test progress bar", "Some information in \%",
                    0, 100, 50)
Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
for(i in u) {
    Sys.sleep(0.1)
    info <- sprintf("%d%% done", round(i))
    setTkProgressBar(pb, i, sprintf("test (%s)", info), info)
}
Sys.sleep(5)
close(pb)

---

**tkStartGUI**  
* Tcl/Tk GUI startup *

**Description**

Starts up the Tcl/Tk GUI

**Usage**

tkStartGUI()

**Details**

Starts a GUI console implemented via a Tk text widget. This should probably be called at most once per session. Also redefines the file pager (as used by `help()`) to be the Tk pager.

**Note**

tkStartGUI() saves its evaluation environment as `.GUIenv`. This means that the user interface elements can be accessed in order to extend the interface. The three main objects are named `term`, `menu`, and `toolbar`, and the various submenus and callback functions can be seen with `ls(envir = `.GUIenv`).

## Try pressing the button, edit the text and when finished:
tkdestroy(tt)

## End(Not run)

---

TkWidgets    Tk widgets

Description
Create Tk widgets and associated R objects.

Usage

tkwidget(parent, type, ...)
tkbutton(parent, ...) tkcanvas(parent, ...) tkcheckbutton(parent, ...) tkentry(parent, ...) ttkentry(parent, ...) tkframe(parent, ...) tklabel(parent, ...) tklistbox(parent, ...) tkmenu(parent, ...) tkmenubutton(parent, ...) tkmessage(parent, ...) tkradiobutton(parent, ...) tkscale(parent, ...) tkscrollbar(parent, ...) tktext(parent, ...) tktopplevel(parent = .TkRoot, ...)
ttkbutton(parent, ...)  
ttkcheckbutton(parent, ...)  
ttkcombobox(parent, ...)  
ttkframe(parent, ...)  
ttkimage(parent, ...)  
ttklabel(parent, ...)  
ttklabelframe(parent, ...)  
ttkmenubutton(parent, ...)  
ttknotebook(parent, ...)  
ttkpanedwindow(parent, ...)  
ttkprogressbar(parent, ...)  
ttkradiobutton(parent, ...)  
ttkseparator(parent, ...)  
ttksizegrip(parent, ...)  
ttktreeview(parent, ...)

Arguments
parent          Parent of widget window.
type            string describing the type of widget desired.
...             handled via .Tcl.args.

Details
These functions create Tk widgets. tkwidget creates a widget of a given type, the others simply call tkwidget with the respective type argument.

The functions starting ttk are for the themed widget set for Tk 8.5 or later. A tutorial can be found at http://www.tkdocs.com.

It is not possible to describe the widgets and their arguments in full. Please refer to the Tcl/Tk documentation.

TkInterface, TkCommands, TkWidgetcmds

Examples
## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
label.widget <- tklabel(tt, text = "Hello, World!")
button.widget <- ttkbutton(tt, text = "Push",
                         command = function()cat("OW!\n"))
tkpack(label.widget, button.widget)  # geometry manager
                         # see Tk-commands

## Push the button and then...

tkdestroy(tt)
tk_choose.dir

Choose a Folder Interactively

Description

Use a Tk widget to choose a directory interactively.

Usage

tk_choose.dir(default = "," , caption = "Select directory")

Arguments

default which directory to show initially.
caption the caption on the selection dialog.

Value

A length-one character vector, character NA if ‘Cancel’ was selected.

See Also

  tk_choose.files

Examples

  ## Not run:
tk_choose.dir(getwd(), "Choose a suitable folder")

  ## End(Not run)
tk_choose.files

Choose a List of Files Interactively

Description

Use a Tk file dialog to choose a list of zero or more files interactively.

Usage

```r
tk_choose.files(default = "", caption = "Select files",
multi = TRUE, filters = NULL, index = 1)
```

Arguments

default
which filename to show initially.
caption
the caption on the file selection dialog.
multi
whether to allow multiple files to be selected.
filters
two-column character matrix of filename filters.
index
unused.

Details

Unlike `file.choose`, `tk_choose.files` will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas `file.choose` would signal an error.

The format of `filters` can be seen from the example. File patterns are specified via extensions, with "*" meaning any file, and "" any file without an extension (a filename not containing a period). (Other forms may work on specific platforms.) Note that the way to have multiple extensions for one file type is to have multiple rows with the same name in the first column, and that whether the extensions are named in file chooser widget is platform-specific. The format may change before release.

Value

A character vector giving zero or more file paths.

Note

A bug in Tk 8.5.0-8.5.4 prevented multiple selections being used.

See Also

`file.choose`, `tk_choose.dir`

Examples

```r
Filters <- matrix(c("R code", ".R", "R code", ".s",
"Text", ".txt", "All files", "*"),
4, 2, byrow = TRUE)
Filters
if(interactive()) tk_choose.files(filter = Filters)
```
**tk_messageBox**  
*Tk Message Box*

**Description**

An implementation of a generic message box using Tk

**Usage**

```r
tk_messageBox(type = c("ok", "okcancel", "yesno", "yesnocancel",  
                 "retrycancel", "aburtretrycancel"),  
               message, caption = "", default = "", ...)  
```

**Arguments**

- **type** character. The type of dialog box. It will have the buttons implied by its name.
- **message** character. The information field of the dialog box.
- **caption** character. The caption on the widget displayed.
- **default** character. The name of the button to be used as the default.
- **...** additional named arguments to be passed to the Tk function of this name. An example is `icon = "warning"`.

**Value**

A character string giving the name of the button pressed.

**See Also**

- `tkmessageBox` for a ‘raw’ interface.

---

**tk_select.list**  
*Select Items from a List*

**Description**

Select item(s) from a character vector using a Tk listbox.

**Usage**

```r
tk_select.list(choices, preselect = NULL, multiple = FALSE,  
               title = NULL)  
```

**Arguments**

- **choices** a character vector of items.
- **preselect** a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially.
- **multiple** logical: can more than one item be selected?
- **title** optional character string for window title, or NULL for no title.
Details

This is a version of `select.list` implemented as a Tk list box plus OK and Cancel buttons. There will be a scrollbar if the list is too long to fit comfortably on the screen.

The dialog box is modal, so a selection must be made or cancelled before the R session can proceed. Double-clicking on an item is equivalent to selecting it and then clicking OK.

If Tk is version 8.5 or later, themed widgets will be used.

Value

A character vector of selected items. If `multiple` is false and no item was selected (or Cancel was used), "" is returned. If `multiple` is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

See Also

`select.list` (a text version except on Windows and the OS X GUI), `menu` (whose graphics = TRUE mode uses this on most Unix-alikes).
Chapter 13

The tools package

**tools-package**  
*Tools for Package Development*

**Description**  
Tools for package development, administration and documentation.

**Details**  
This package contains tools for manipulating R packages and their documentation. For a complete list of functions, use `library(help = "tools")`.

**Author(s)**  
Kurt Hornik and Friedrich Leisch  
Maintainer: R Core Team <R-core@r-project.org>

**.print.via.format**  
*Printing Utilities*

**Description**  
`.print.via.format` is a “prototype” `print()` method, useful, at least as a start, by a simple

```r
  print.<myS3class> <- .print.via.format
```

**Usage**  
`.print.via.format(x, ...)`

**Arguments**  
x object to be printed.  
... optional further arguments, passed to `format`. 

1657
Value

x, invisibly (by `invisible()`), as `print` methods should.

See Also

The `print` generic; its default method `print.default` (used for many basic implicit classes such as "numeric", "character" and arrays of them, `lists` etc).

Examples

```r
## The function is simply defined as
function (x, ...) {
  writelines(format(x, ...))
  invisible(x)
}

## is used for simple print methods in R, and as prototype for new methods.
```

---

`add_datalist`  
Add a ‘datalist’ File to a Package

Description

The `data()` command with no arguments lists all the datasets available via `data` in attached packages, and to do so a per-package list is installed. Creating that list at install time can be slow for packages with huge datasets, and can be expedited by a supplying ‘data/datalist’ file.

Usage

`add_datalist(pkgpath, force = FALSE)`

Arguments

- `pkgpath`  
The path to a (source) package.
- `force`  
Logical: can an existing ‘data/datalist’ file be over-written?

Details

R CMD `build` will call this function to add a data list to packages with 1MB or more of data.

It is also helpful to give a ‘data/datalist’ file in packages whose datasets have many dependencies, including loading the packages itself (and maybe others).

See Also

- `data`.

The ‘Writing R Extensions’ manual.
assertCondition

Asserting Error Conditions

Description
When testing code, it is not sufficient to check that results are correct, but also that errors or warnings are signalled in appropriate situations. The functions described here provide a convenient facility for doing so. The three functions check that evaluating the supplied expression produces an error, a warning or one of a specified list of conditions, respectively. If the assertion fails, an error is signalled.

Usage
assertError(expr, verbose = FALSE)
assertWarning(expr, verbose = FALSE)
assertCondition(expr, ..., .exprString = , verbose = FALSE)

Arguments
expr an unevaluated \texttt{R} expression which will be evaluated via \texttt{tryCatch(expr, ...)}.  
... character strings corresponding to the classes of the conditions that would satisfy the assertion; e.g., "error" or "warning". If none are specified, any condition will satisfy the assertion. See the details section.  
.exprString The string to be printed corresponding to expr. By default, the actual expr will be deparsed. Will be omitted if the function is supplied with the actual expression to be tested. If assertCondition() is called from another function, with the actual expression passed as an argument to that function, supply the deparsed version.  
verbose If TRUE, a message is printed when the condition is satisfied.

Details
assertCondition() uses the general condition mechanism to check all the conditions generated in evaluating expr. The occurrence of any of the supplied condition classes among these satisfies the assertion regardless of what other conditions may be signalled.  
assertError() is a convenience function for asserting errors; it calls assertCondition().  
assertWarning() asserts that a warning will be signalled, but not an error, whereas assertCondition(expr, "warning") will be satisfied even if an error follows the warning. See the examples.

Value
If the assertion is satisfied, a list of all the condition objects signalled is returned, invisibly. See \texttt{conditionMessage} for the interpretation of these objects. Note that all conditions signalled during the evaluation are returned, whether or not they were among the requirements.

Author(s)
John Chambers and Martin Maechler
See Also

stop.warning, signalCondition, tryCatch.

Examples

```r
assertError(sqrt("abc"))
assertWarning(matrix(1:8, 4,3))

assertCondition( "-1" ) # ok, any condition would satisfy this

try( assertCondition(sqrt(2), "warning") )
## .. Failed to get warning in evaluating sqrt(2)
assertCondition(sqrt("abc"), "error") # ok
try( assertCondition(sqrt("abc"), "warning") )# -> error: had no warning
assertCondition(sqrt("abc"), "error")
## identical to assertError() call above

assertCondition(matrix(1:5, 2,3), "warning")
try( assertCondition(matrix(1:8, 4,3), "error") )
## .. Failed to get expected error ....

## either warning or worse:
assertCondition(matrix(1:8, 4,3), "error","warning") # OK
assertCondition(matrix(1:8, 4,3), "warning") # OK

## when both are signalled:
ff <- function() { warning("my warning"); stop("my error") }
assertWarning(ff(), "warning")
## but assertWarning does not allow an error to follow
try(assertWarning(ff()))
assertCondition(ff(), "error") # ok
assertCondition(ff(), "error", "warning") # ok (quietly, catching warning)

## assert that assertC..() does not assert [and use *one* argument only]
assertCondition( assertCondition(sqrt(2 ), "warning") )
assertCondition( assertCondition(sqrt("abc"), "warning"), "error")
assertCondition( assertCondition(matrix(1:8, 4,3), "error"),
                   "error")
```

Description

This function defines and registers styles for rendering `bibentry` objects into ‘Rd’ format, for later conversion to text, HTML, etc.

Usage

```r
bibstyle(style, envir, ..., .init = FALSE, .default = TRUE) getBibestyle(all = FALSE)
```
bibstyle

Arguments

style A character string naming the style.
environ (optional) An environment holding the functions to implement the style.
... Named arguments to add to the environment.
.init Whether to initialize the environment from the default style "JSS".
.default Whether to set the specified style as the default style.
all Whether to return the names of all registered styles.

Details

Rendering of bibentry objects may be done using routines modelled after those used by BibTeX. This function allows environments to be created and manipulated to contain those routines.

There are two ways to create a new style environment. The easiest is to set .init = TRUE, in which case the environment will be initialized with a copy of the default "JSS" environment. (This style is modelled after the 'jss.bst' style used by the Journal of Statistical Software.) Alternatively, the environ argument can be used to specify a completely new style environment.

To find the name of the default style, use getBibstyle(). To retrieve an existing style without setting it as the default, use bibstyle(style, .default = FALSE). To modify an existing style, specify style and some named entries via .... (Modifying the default "JSS" style is discouraged.) Setting style to NULL or leaving it missing will retrieve the default style, but modifications will not be allowed.

At a minimum, the environment should contain routines to render each of the 12 types of bibliographic entry supported by bibentry as well as several other routines described below. The former must be named formatArticle, formatBook, formatInbook, formatIncollection, formatInproceedings, formatManual, formatMastersthesis, formatMisc, formatPhdthesis, formatProceedings, formatTechreport and formatUnpublished. Each of these takes one argument, a single unclassed entry from the bibentry vector passed to the renderer, and should produce a single element character vector (possibly containing newlines).

The other routines are as follows. sortKeys, a function to produce a sort key to sort the entries, is passed the original bibentry vector and should produce a sortable vector of the same length to define the sort order. Finally, the optional function cite should have the same argument list as utils::cite, and should produce a citation to be used in text.

The format method for "bibentry" objects adds a field named ".index" to each entry after sorting and before formatting. This is a 1-based index within the complete object that can be used in styles that require numbering. Although the "JSS" style doesn't use numbers, it includes a fmtPrefix() stub function that may be used to display them. See the example below.

Value

bibstyle returns the environment which has been selected or created.
getBibstyle returns the name of the default style, or all style names.

Author(s)

Duncan Murdoch

bibentry
Examples

refs <-

bibstyle("unsorted", sortKeys = function(refs) seq_along(refs), fmtPrefix = function(paper) paste0("[", paper$index, "]"), .init = TRUE)
print(refs, .bibstyle = "unsorted")

Description

Build one vignette

Run Sweave (or other custom weave function) texi2dvi, and/or Stangle (or other custom tangle function) on one vignette.

This is the workhorse of R CMD Sweave.

Usage

buildVignette(file, dir = ".", weave = TRUE, latex = TRUE, tangle = TRUE, quiet = TRUE, clean = TRUE, keep = character(), engine = NULL, buildPkg = NULL, encoding, ...)

Arguments

file character; the vignette source file
dir character; the working directory in which the intermediate and output files will be produced
weave logical; should weave be run?
latex logical; texi2pdf be run if weaving produces a `.tex` file?
tangle logical; should tangle be run?
quiet logical; run in quiet mode?
clean logical; whether to remove some newly created, often intermediate, files. See details below.
keep

a list of file names to keep in any case when cleaning. Note that “target” files are kept anyway.

engine

NULL or character; name of vignette engine to use. Overrides any \VignetteEngine() markup in the vignette.

buildPkg

NULL or character; an optional package in which to find the vignette engine.

encoding

the encoding to assume for the file. If not specified, it will be inferred from the file contents.

... Additional arguments passed to weave and tangle.

Details

This function determines the vignette engine for the vignette (default utils::Sweave), then weaves and/or tangles the vignette using that engine. Finally, if clean is TRUE, newly created intermediate files (non “targets”, where these depend on the engine, etc. and not any in keep) will be deleted. If clean is NA, and weave is true, newly created intermediate output files (e.g., ‘.tex’) will not be deleted even if a ‘.pdf’ file has been produced from them.

If buildPkg is specified, it will be loaded before the vignette is processed, and will be used as the default package in the search for a vignette engine, but an explicitly specified package in the vignette source (e.g., using \VignetteEngine(utils::Sweave) to specify the Sweave engine in the utils package) will override it. In contrast, if the engine argument is given, it will override the vignette source.

Value

A character vector naming the files that have been produced.

Author(s)

Henrik Bengtsson and Duncan Murdoch

buildVignettes for building all vignettes in a package.
Arguments

package a character string naming an installed package. If given, vignette source files are by default looked for in subdirectory ‘doc’.
dir a character string specifying the path to a package’s root source directory. This subdirectory ‘vignettes’ (or if it does not exist ‘inst/doc’) is searched for vignette source files.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
quiet logical. Weave and run texi2pdf in quiet mode.
clean Remove all files generated by the build, even if there were copies there before.
tangle logical. Do tangling as well as weaving.
subdirs a character vector of subdirectories of dir in which to look for vignettes. The first which exists is used. Defaults to “doc” if package is supplied, otherwise “vignettes”.
output logical indicating if the output filenames for each vignette should be returned (in component outputs).
source logical indicating if the tangled output filenames for each vignette should be returned (in component sources).
check logical. If TRUE, check whether all files that have vignette-like filenames have an identifiable vignette engine. This may be a false positive if a file is not a vignette but has a filename matching a pattern defined by one of the vignette engines.

Details

buildVignettes is used by R CMD build and R CMD check to (re-)build vignette PDFs from their sources.

Value

buildVignettes is called for its side effect of creating the PDF versions of all vignettes, and if tangle = TRUE, extracting the R code.
pkgVignettes returns an object of class "pkgVignettes" if a vignette directory is found, otherwise NULL.

Examples

gVigns <- pkgVignettes("grid")
str(gVignettes)

charsets

Conversion Tables between Character Sets

Description

charset_to_Unicode is a matrix of Unicode code points with columns for the common 8-bit encodings.
Adobe_glyphs is a data frame which gives Adobe glyph names for Unicode code points. It has two character columns, "adobe" and "unicode" (a 4-digit hex representation).
Usage

```r
charset_to_Unicode
Adobe_glyphs
```

Details

`charset_to_Unicode` is an integer matrix of class `c("noquote", "hexmode")` so prints in hexadecimal. The mappings are those used by libiconv: there are differences in the way quotes and minus/hyphen are mapped between sources (and the postscript encoding files use a different mapping).

`Adobe_glyphs` includes all the Adobe glyph names which correspond to single Unicode characters. It is sorted by Unicode code point and within a point alphabetically on the glyph (there can be more than one name for a Unicode code point). The data are in the file `R_HOME/share/encodings/Adobe_glyphlist`.

Source

```r
```

Examples

```r
## find Adobe names for ISOLatin2 chars.
latin2 <- charset_to_Unicode[, "ISOLatin2"]
aUnicode <- as.numeric(paste0("0x", Adobe_glyphs$unicode))
keep <- aUnicode %in% latin2
aUnicode <- aUnicode[keep]
AA <- Adobe_glyphs[keep, 1]
## first match
ALatin2 <- AA[match(latin2, aUnicode)]
## all matches
BLatin2 <- lapply(1:256, function(x) AA[aUnicode == latin2[x]])
format(BLatin2, justify = "none")
```

### checkFF

**Check Foreign Function Calls**

Description

Performs checks on calls to compiled code from R code. Currently only checks whether the interface functions such as `.C` and `.Fortran` are called with a `"NativeSymbolInfo"` first argument or with argument `PACKAGE` specified, which is highly recommended to avoid name clashes in foreign function calls.

Usage

```r
checkFF(package, dir, file, lib.loc = NULL,
registration = FALSE, check_DUP = FALSE,
verbose = getOption("verbose"))
```
Arguments

package a character string naming an installed package. If given, the installed R code of the package is checked.
dir a character string specifying the path to a package's root source directory. This should contain the subdirectory 'R' (for R code). Only used if package is not given.
file the name of a file containing R code to be checked. Used if neither package nor dir are given.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
registration a logical. If TRUE, checks the registration information on the call (if available).
check_DUP a logical. If TRUE, .C and .Fortran calls with DUP = FALSE are reported.
verbose a logical. If TRUE, additional diagnostics are printed (and the result is returned invisibly).

Details

Note that we can only check if the name argument is a symbol or a character string, not what class of object the symbol resolves to at run-time.

If the package has a namespace which contains a useDynLib directive, calls in top-level functions in the package are not reported as their symbols will be preferentially looked up in the DLL named in the first useDynLib directive.

This checks that calls with PACKAGE specified are to the same package, and reports separately those which are in base packages and those which are in other packages (and if those packages are specified in the ‘DESCRIPTION’ file).

Value

An object of class "checkFF".

There are format and print methods to display the information contained in such objects.

See Also

Examples

# order is pretty much random
cHECKF (package = "stats", verbose = TRUE)
checkMD5sums  

**Description**  
checkMD5sums checks the files against a file "MD5".

**Usage**  
checkMD5sums(package, dir)

**Arguments**  
- **package**: the name of an installed package  
- **dir**: the path to the top-level directory of an installed package.

**Details**  
The file 'MD5' which is created is in a format which can be checked by `md5sum -c MD5` if a suitable command-line version of `md5sum` is available. (For Windows, one is supplied in the bundle at [http://cran.r-project.org/bin/windows/Rtools](http://cran.r-project.org/bin/windows/Rtools).)

If `dir` is missing, an installed package of name `package` is searched for.

The private function `tools:::installMD5sums` is used to create `MD5` files in the Windows build.

**Value**  
checkMD5sums returns a logical, NA if there is no 'MD5' file to be checked.

**See Also**  
- `md5sum`

checkPoFiles  

**Description**  
These functions compare formats embedded in English messages with translated strings to check for consistency. checkPoFile checks one file, while checkPoFiles checks all files for a specified language.

**Usage**  
checkPoFile(f, strictPlural = FALSE)  
checkPoFiles(language, dir = ".")
Arguments

f  a character string giving a single filepath.
strictPlural  whether to compare formats of singular and plural forms in a strict way.
language  a character string giving a language code.
dir  a path to a directory in which to check files.

Details

Part of R’s internationalization depends on translations of messages in ‘.po’ files. In these files an ‘English’ message taken from the R sources is followed by a translation into another language. Many of these messages are format strings for C or R `sprintf` and related functions. In these cases, the translation must give a compatible format or an error will be generated when the message is displayed.

The rules for compatibility differ between C and R in several ways. C supports several conversions not supported by R, namely c, u, p, n. It is allowed in C’s `sprintf()` function to have more arguments than are needed by the format string, but in R the counts must match exactly. R requires types of arguments to match, whereas C will do the display whether it makes sense or not.

These functions compromise on the testing as follows. The additional formats allowed in C are accepted, and all differences in argument type or count are reported. As a consequence some reported differences are not errors.

If the `strictPlural` argument is TRUE, then argument lists must agree exactly between singular and plural forms of messages; if FALSE, then translations only need to match one or the other of the two forms. When `checkPoFiles` calls `checkPoFile`, the `strictPlural` argument is set to TRUE for files with names starting ‘R-’, and to FALSE otherwise.

Items marked as ‘fuzzy’ in the ‘.po’ file are not processed (as they are ignored by the message compiler).

If a difference is found, the translated string is checked for variant percent signs (e.g., the wide percent sign “\uff05”). Such signs will not be recognized as format specifiers, and are likely to be errors.

Value

Both functions return an object of S3 class "check_po_files". A `print` method is defined for this class to display a report on the differences.

Author(s)

Duncan Murdoch

References

See the GNU gettext manual for the ‘.po’ file format:

`update_pkg_po()` which calls `checkPoFile()`; `xgettext`, `sprintf`. 
checkRd

Examples

```r
# Not run:
checkPoFiles("de", "/path/to/R/src/directory")

# End(Not run)
```

checkRd  

Check an Rd Object

Description

Check an help file or the output of the `parse_Rd` function.

Usage

```r
checkRd(Rd, defines = .Platform$OS.type, stages = "render",
unknownOK = TRUE, listOK = TRUE, ..., def_enc = FALSE)
```

Arguments

- `Rd`  
  a filename or Rd object to use as input.
- `defines`  
  string(s) to use in #ifdef tests.
- `stages`  
  at which stage ("build", "install", or "render") should \Sexpr macros be executed? See the notes below.
- `unknownOK`  
  unrecognized macros are treated as errors if FALSE, otherwise warnings.
- `listOK`  
  unnecessary non-empty braces (e.g., around text, not as an argument) are treated as errors if FALSE, otherwise warnings.
- `...`  
  additional parameters to pass to `parse_Rd` when Rd is a filename. One that is often useful is `encoding`.
- `def_enc`  
  logical: has the package declared an encoding, so tests for non-ASCII text are suppressed?

Details

checkRd performs consistency checks on an Rd file, confirming that required sections are present, etc.

It accepts a filename for an Rd file, and will use `parse_Rd` to parse it before applying the checks. If so, warnings from `parse_Rd` are collected, together with those from the internal function `prepare_Rd`, which does the #ifdef and \Sexpr processing, drops sections that would not be rendered or are duplicated (and should not be) and removes empty sections.

An Rd object is passed through `prepare_Rd`, but it may already have been (and installed Rd objects have).

Warnings are given a `level`: those from `prepare_Rd` have level 0. These include

- All text must be in a section
- Only one tag `name` section is allowed: the first will be used
- Section `name` is unrecognized and will be dropped
- Dropping empty section `name`
checkRd itself can show

+ Tag tag name not recognized
+ \tabular format must be simple text
+ Unrecognized \tabular format: ...
+ Only \emph{n} columns allowed in this table
+ Must have a \texttt{tag name}
+ Only one \texttt{tag name} is allowed
+ Tag \texttt{tag name} must not be empty
+ \texttt{docType} must be plain text
+ Tag \texttt{method} is only valid in \texttt{usage}
+ Tag \texttt{dontrun} is only valid in \texttt{examples}
+ Tag \texttt{tag name} is invalid in a \texttt{block name} block
+ Title of \texttt{section} must be non-empty plain text
+ \texttt{title content} must be plain text
+ Empty section \texttt{tag name}

and variations with \texttt{method} replaced by \texttt{S3method} or \texttt{S4method}.

Note that both \texttt{prepare.Rd} and \texttt{checkRd} have tests for an empty section: that in \texttt{checkRd} is stricter (essentially that nothing is output).

**Value**

This may fail through an \texttt{R} error, but otherwise warnings are collected as returned as an object of class "checkRd", a character vector of messages. This class has a \texttt{print} method which only prints unique messages, and has argument \texttt{minlevel} that can be used to select only more serious messages. (This is set to -1 in \texttt{R CMD check}.)

Possible fatal errors are those from running the parser (e.g., a non-existent file, unclosed quoted string, non-ASCII input without a specified encoding) or from \texttt{prepare.Rd} (multiple \texttt{RdVersion} declarations, invalid \texttt{encoding} or \texttt{docType} or \texttt{name} sections, and missing or duplicate \texttt{name} or \texttt{title} sections).

\texttt{parse.Rd}, \texttt{Rd2HTML}.
checkRdaFiles  

Report on Details of Saved Images or Re-saves them

Description

This reports for each of the files produced by `save` the size, if it was saved in ASCII or XDR binary format, and if it was compressed (and if so in what format). Usually such files have extension `.rda` or `.RData`, hence the name of the function.

Usage

```r
checkRdaFiles(paths)
resaveRdaFiles(paths, compress = c("auto", "gzip", "bzip2", "xz"),

 compression_level

Arguments

paths A character vector of paths to `save` files. If this specifies a single directory, it is taken to refer to all `.rda` and `.RData` files in that directory.
compress, compression_level
type and level of compression: see `save`.

Details

compress = "auto" asks R to choose the compression and ignores compression_level. It will try "gzip", "bzip2" and if the "gzip" compressed size is over 10Kb, "xz" and choose the smallest compressed file (but with a 10% bias towards "gzip"). This can be slow.

Value

For checkRdaFiles, a data frame with rows names `paths` and columns

size numeric: file size in bytes, NA if the file does not exist.
ASCII logical: true for save(ASCII = TRUE), NA if the format is not that of an R save file.
compress character: type of compression. One of "gzip", "bzip2", "xz", "none" or "unknown" (which means that if this is an R save file it is from a later version of R).
version integer: the version of the save – usually 2 but 1 for very old files, and NA for other files.

Examples

```r
## Not run:
## from a package top-level source directory
paths <- sort(Sys.glob(c("data/*.rda", "data/*.RData")))
(res <- checkRdaFiles(paths))
## pick out some that may need attention
bad <- is.na(res$ASCII) | res$ASCII | (res<size > 1e4 & res$compress == "none")
res[bad, ]

## End(Not run)
checkTnF  

Description  

Checks the specified R package or code file for occurrences of T or F, and gathers the expression containing these. This is useful as in R T and F are just variables which are set to the logicals TRUE and FALSE by default, but are not reserved words and hence can be overwritten by the user. Hence, one should always use TRUE and FALSE for the logicals.

Usage  

checkTnF(package, dir, file, lib.loc = NULL)

Arguments  

package  
a character string naming an installed package. If given, the installed R code and the examples in the documentation files of the package are checked. R code installed as an image file cannot be checked.

dir  
a character string specifying the path to a package’s root source directory. This must contain the subdirectory ‘R’ (for R code), and should also contain ‘man’ (for documentation). Only used if package is not given. If used, the R code files and the examples in the documentation files are checked.

file  
the name of a file containing R code to be checked. Used if neither package nor dir are given.

lib.loc  
a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.

Value  

An object of class "checkTnF" which is a list containing, for each file where occurrences of T or F were found, a list with the expressions containing these occurrences. The names of the list are the corresponding file names.

There is a print method for nicely displaying the information contained in such objects.

checkVignettes  

Description  

Check all Sweave files of a package by running Sweave and/or Stangle on them. All R source code files found after the tangling step are sourced to check whether all code can be executed without errors.
checkVignettes

Usage

checkVignettes(package, dir, lib.loc = NULL,
    tangle = TRUE, weave = TRUE, latex = FALSE,
    workdir = c("tmp", "src", "cur"),
    keepfiles = FALSE)

Arguments

package  a character string naming an installed package. If given, Sweave files are
searched in subdirectory ‘doc’.

dir  a character string specifying the path to a package’s root source directory. This
subdirectory ‘inst/doc’ is searched for Sweave files.

lib.loc  a character vector of directory names of \textsf{R} libraries, or NULL. The default value
of NULL corresponds to all libraries currently known. The specified library trees
are used to search for package.

tangle  Perform a tangle and \textbf{source} the extracted code?

weave  Perform a weave?

latex  logical: if weave and latex are TRUE and there is no ‘Makefile’ in the vignettes
directory, run the weaved files through \textsf{pdflatex}.

workdir  Directory used as working directory while checking the vignettes. If
"tmp" then a temporary directory is created, this is the default. If "src" then the direc-
tory containing the vignettes itself is used, if "cur" then the current working
directory of \textsf{R} is used.

keepfiles  Delete files in the temporary directory? This option is ignored when
workdir != "tmp".

Details

A ‘vignette’ is a file in the package’s ‘inst/doc’ directory with extension ‘.Rnw’ (preferred),
‘.Snw’, ‘.Rtex’ or ‘.Stex’ (and lower-case versions are also accepted).

If tangle is true, this function runs \textsf{Stangle} to produce (one or more) \textsf{R} code files from each
vignette, then sources each code file in turn.

If weave is true, the vignettes are run through \textsf{Sweave}, which will produce a ‘.tex’ file for each
vignette. If latex is also true, \textsf{texi2pdf} is run on the ‘.tex’ files from those vignettes which did
not give errors in the previous steps.

Value

An object of class "checkVignettes", which is a list with the error messages found during the
tangle, source, weave and latex steps. There is a print method for displaying the information
contained in such objects.
check_packages_in_dir  Check Source Packages and Their Reverse Dependencies

Description

Check source packages in a given directory, optionally with their reverse dependencies.

Usage

check_packages_in_dir(dir,
    check_args = character(),
    check_args_db = list(),
    reverse = NULL,
    check_env = character(),
    xvfb = FALSE,
    Ncpus = getopt("Ncpus", 1L),
    clean = TRUE,
    ...
)

summarize_check_packages_in_dir_results(dir, all = TRUE,
    full = FALSE)
summarize_check_packages_in_dir_timings(dir, all = FALSE,
    full = FALSE)
summarize_check_packages_in_dir_depends(dir, all = FALSE)

Arguments

dir    a character string giving the path to the directory with the source `.tar.gz` files to be checked.
check_args    a character vector with arguments to be passed to R CMD check, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively.
check_args_db    a named list of character vectors with arguments to be passed to R CMD check, with names the respective package names.
reverse    a list with names partially matching "repos", "which", or "recursive", giving the repositories to use for locating reverse dependencies (default: getopt("repos")), the types of reverse dependencies (default: c("Depends", "Imports", "LinkingTo")), and indicating whether to also check reverse dependencies of reverse dependencies (and so on), or NULL (default), in which case no reverse dependencies are checked.
check_env    a character vector of name=value strings to set environment variables for checking, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively.
xvfb    a logical indicating whether to perform checking inside a virtual framebuffer X server (Unix only), or a character vector of Xvfb options for doing so.
Ncpus    the number of parallel processes to use for parallel installation and checking.
clean    a logical indicating whether to remove the downloaded reverse dependency sources.
...    currently not used.
a logical indicating whether to also summarize the reverse dependencies checked.

full a logical indicating whether to also give details for checks with non-ok results, or summarize check example timings (if available).

Details

check_packages_in_dir allows to conveniently check source package `.tar.gz` files in the given directory `dir`, along with their reverse dependencies as controlled by `reverse`.

The "which" component of `reverse` can also be a list, in which case reverse dependencies are obtained for each element of the list and the corresponding element of the "recursive" component of `reverse` (which is recycled as needed).

If needed, the source `.tar.gz` files of the reverse dependencies to be checked as well are downloaded into `dir` (and removed at the end if `clean` is true). Next, all packages (additionally) needed for checking are installed to the ‘Library’ subdirectory of `dir`. Then, all `.tar.gz` files are checked using the given arguments and environment variables, with outputs and messages to files in the ‘Outputs’ subdirectory of `dir`. The ‘*.check’ directories with the check results of the reverse dependencies are renamed by prefixing their base names with ‘rdepends_’.

Results and timings can conveniently be summarized using `summarize_check_packages_in_dir_results` and `summarize_check_packages_in_dir_timings`, respectively.

Installation and checking is performed in parallel if `Ncpus` is greater than one: this will use `mclapply` on Unix and `partLapply` on Windows.

Note

This functionality is still experimental: interfaces may change in future versions.

codoc Check Code/Documentation Consistency

Description

Find inconsistencies between actual and documented ‘structure’ of R objects in a package. codoc compares names and optionally also corresponding positions and default values of the arguments of functions. codocClasses and codocData compare slot names of S4 classes and variable names of data sets, respectively.

Usage

```r
codoc(package, dir, lib.loc = NULL, use.values = NULL, verbose = getOption("verbose"))
codocClasses(package, lib.loc = NULL)
codocData(package, lib.loc = NULL)
```
Arguments

package a character string naming an installed package.
dir a character string specifying the path to a package’s root source directory. This must contain the subdirectories ‘man’ with R documentation sources (in Rd format) and ‘R’ with R code. Only used if package is not given.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
use.values if FALSE, do not use function default values when comparing code and docs. Otherwise, compare all default values if TRUE, and only the ones documented in the usage otherwise (default).
verbose a logical. If TRUE, additional diagnostics are printed.

Details

The purpose of codoc is to check whether the documented usage of function objects agrees with their formal arguments as defined in the R code. This is not always straightforward, in particular as the usage information for methods to generic functions often employs the name of the generic rather than the method.

The following algorithm is used. If an installed package is used, it is loaded (unless it is the base package), after possibly detaching an already loaded version of the package. Otherwise, if the sources are used, the R code files of the package are collected and sourced in a new environment. Then, the usage sections of the Rd files are extracted and parsed ‘as much as possible’ to give the formals documented. For interpreted functions in the code environment, the formals are compared between code and documentation according to the values of the argument use.values. Synopsis sections are used if present; their occurrence is reported if verbose is true.

If a package has a namespace both exported and unexported objects are checked, as well as registered S3 methods. (In the unlikely event of differences the order is exported objects in the package, registered S3 methods and finally objects in the namespace and only the first found is checked.)

Currently, the R documentation format has no high-level markup for the basic ‘structure’ of classes and data sets (similar to the usage sections for function synopses). Variable names for data frames in documentation objects obtained by suitably editing ‘templates’ created by prompt are recognized by codocData and used provided that the documentation object is for a single data frame (i.e., only has one alias). codocClasses analogously handles slot names for classes in documentation objects obtained by editing shells created by promptClass.

Help files named ‘pkgname-defunct.Rd’ for the appropriate pkgname are checked more loosely, as they may have undocumented arguments.

Value

codoc returns an object of class "codoc". Currently, this is a list which, for each Rd object in the package where an inconsistency was found, contains an element with a list of the mismatches (which in turn are lists with elements code and docs, giving the corresponding arguments obtained from the function’s code and documented usage).

codocClasses and codocData return objects of class "codocClasses" and "codocData", respectively, with a structure similar to class "codoc".

There are print methods for nicely displaying the information contained in such objects.
Note

The default for use values has been changed from FALSE to NULL, for R versions 1.9.0 and later.

undo, QC

compactPDF

Description

Re-save PDF files (especially vignettes) more compactly. Support function for R CMD build --compact-vignettes.

Usage

compactPDF(paths, qpdf = Sys.which(Sys.getenv("R_QPDF", "qpdf")), gs_cmd = Sys.getenv("R_GSCMD", ""), gs_quality = Sys.getenv("GS_QUALITY", "none"), gs_extras = character())

## S3 method for class 'compactPDF'
format(x, ratio = 0.9, diff = 1e4, ...)

Arguments

paths A character vector of paths to PDF files, or a length-one character vector naming a directory, when all '.pdf' files in that directory will be used.
qpdf Character string giving the path to the qpdf command. If empty, qpdf will not be used.
gs_cmd Character string giving the path to the GhostScript executable, if that is to be used. On Windows this is the path to 'gswin32c.exe' or 'gswin64c.exe'. If "" (the default), the function will try to find a platform-specific path to GhostScript where required.
gs_quality A character string indicating the quality required: the options are "none" (so GhostScript is not used), "printer" (300dpi), "ebook" (150dpi) and "screen" (72dpi).
gs_extras An optional character vector of further options to be passed to GhostScript.
x An object of class "compactPDF".
ratio, diff Limits for reporting: files are only reported whose sizes are reduced both by a factor of ratio and by diff bytes.
... Further arguments to be passed to or from other methods.
Details

This by default makes use of qpdf, available from http://qpdf.sourceforge.net/ (including as a Windows binary) and included with the CRAN OS X distribution of R. If gs_cmd is non-empty and gs_quality ! = "none", GhostScript will used first, then qpdf if it is available. If gs_quality ! = "none" and gs_cmd is ", an attempt will be made to find a GhostScript executable. qpdf and/or gs_cmd are run on all PDF files found, and those which are reduced in size by at least 10% and 10Kb are replaced.

The strategy of our use of qpdf is to (losslessly) compress both PDF streams and objects. GhostScript compresses streams and more (including downsampling and compressing embedded images) and consequently is much slower and may lose quality (but can also produce much smaller PDF files). However, quality "ebook" is perfectly adequate for screen viewing and printing on laser printers.

Where PDF files are changed they will become PDF version 1.5 files: these have been supported by Acrobat Reader since version 6 in 2003, so this is very unlikely to cause difficulties.

Stream compression is what most often has large gains. Most PDF documents are generated with object compression, but this does not seem to be the default for MiKTeX’s pdfLaTeX. For some PDF files (and especially package vignettes), using GhostScript can dramatically reduce the space taken by embedded images (often screenshots).

Where both GhostScript and qpdf are selected (when gs_quality ! = "none" and both executables are found), they are run in that order and the size reductions apply to the total compression achieved.

Value

An object of class c("compactPDF", "data.frame"). This has two columns, the old and new sizes in bytes for the files that were changed.

There are format and print methods: the latter passes ... to the format method, so will accept ratio and diff arguments.

Note

The external tools used may change in future releases.

Versions of GhostScript 9.06 and later give several times better compression than 9.05 on some vignettes in CRAN packages.

See Also

resaveRdaFiles.

Many other (and sometimes more effective) tools to compact PDF files are available, including Adobe Acrobat (not Reader). See the ‘Writing R Extensions’ manual.

delimMatch        Delimited Pattern Matching

Description

Match delimited substrings in a character vector, with proper nesting.
Usage

delimMatch(x, delim = c("{", ""), syntax = "Rd")

Arguments

x a character vector.
delim a character vector of length 2 giving the start and end delimiters. Future versions might allow for arbitrary regular expressions.
syntax currently, always the string "Rd" indicating Rd syntax (i.e., '%' starts a comment extending till the end of the line, and '\' escapes). Future versions might know about other syntax, perhaps via 'syntax tables' allowing to flexibly specify comment, escape, and quote characters.

Value

An integer vector of the same length as x giving the starting position (in characters) of the first match, or -1 if there is none, with attribute "match.length" giving the length (in characters) of the matched text (or -1 for no match).

See Also

regexpr for 'simple' pattern matching.

Examples

x <- c("\value(foo)", "function(bar)"
     delimMatch(x)
     delimMatch(x, c("",""))

dependsOnPkgs Find Reverse Dependencies

Description

Find 'reverse' dependencies of packages, that is those packages which depend on this one, and (optionally) so on recursively.

Usage

dependsOnPkgs(pkgs,
    dependencies = c("Depends", "Imports", "LinkingTo"),
    recursive = TRUE, lib.loc = NULL,
    installed =
    installed.packages(lib.loc, fields = "Enhances"))
Arguments

pkgs a character vector of package names.
dependencies a character vector listing the types of dependencies, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Character string "all" is shorthand for that vector.
recursive logical: should reverse dependencies of reverse dependencies (and so on) be included?
lib.loc a character vector of R library trees, or NULL for all known trees (see .libPaths).
installed a result of calling installed.packages.

Value

A character vector of package names, which does not include any from pkgs.

Examples

## there are few dependencies in a vanilla R installation:
## lattice may not be installed
dependsOnPkgs("lattice")

encoded_text_to_latex  Translate non-ASCII Text to LaTeX Escapes

Description

Translate non-ASCII characters in text to LaTeX escape sequences.

Usage

encoded_text_to_latex(x, encoding = c("latin1", "latin2", "latin9", "UTF-8", "utf8"))

Arguments

x a character vector.
encoding the encoding to be assumed. "latin9" is officially ISO-8859-15 or Latin-9, but known as latin9 to LaTeX’s inputenc package.

Details

Non-ASCII characters in x are replaced by an appropriate LaTeX escape sequence, or ‘?’ if there is no appropriate sequence.

Even if there is an appropriate sequence, it may not be supported by the font in use. Hyphen is mapped to ‘\-’. 

Value

A character vector of the same length as x.
Examples

x <- "fa\x7Eile"
encoded_text_to_latex(x, "latin1")
## Not run:
## create a tex file to show the upper half of 8-bit charsets
x <- rawToChar(as.raw(160:255), multiple = TRUE)
(xx <- matrix(x, ncol = 16, byrow = TRUE))
xx[1] <- encoded_text_to_latex(x, "latin1") # or latin2 or latin9
xx <- apply(xx, 1, paste, collapse = "&")
con <- file("test-encoding.tex", "w")
header <- c("\\documentclass[article]",
"\\usepackage[T1]{fontenc}",
"\\usepackage{rd}",
"\\begin{document}",
"\\HeaderA\{test\}\{test\}",
"\\begin\{Details\}\{relax\}",
"\\Tabular\{cccccccccccccccc\}\{\}",
trailer <- c("\"", "\\end\{Details\}\{\\end\{document\}\}
writeLines(header, con)
writeLines(paste0(xx, "\""), con)
writeLines(trailer, con)
close(con)
## and some UTF_8 chars
x <- intToUtf8(as.integer(
  c(160:383,0x0192,0x02C6,0x02C7,0x02CA,0x02D8,
    0x02D9,0x02DD,0x200C,0x2018,0x2019,0x201C,
    0x201D,0x2020,0x2022,0x2026,0x20AC)),
multiple = TRUE)
xx <- x
xx[1] <- encoded_text_to_latex(x, "UTF-8")
xx <- apply(xx, 1, paste, collapse = "&")
con <- file("test-utf8.tex", "w")
writeLines(header, con)
writeLines(paste(xx, "\""), con)
writeLines(trailer, con)
close(con)
## End(Not run)
Usage

file_ext(x)
file_path_as_absolute(x)
file_path_sans_ext(x, compression = FALSE)

list_files_with_exts(dir, exts, all.files = FALSE,
    full.names = TRUE)
list_files_with_type(dir, type, all.files = FALSE,
    full.names = TRUE, OS_subdirs = .OS_type())

Arguments

x character vector giving file paths.
compression logical: should compression extension ‘.gz’, ‘.bz2’ or ‘.xz’ be removed first?
dir a character string with the path name to a directory.
exts a character vector of possible file extensions (excluding the leading dot).
all.files a logical. If FALSE (default), only visible files are considered; if TRUE, all files are used.
full.names a logical indicating whether the full paths of the files found are returned (default), or just the file names.
type a character string giving the ‘type’ of the files to be listed, as characterized by their extensions. Currently, possible values are "code" (R code), "data" (data sets), "demo" (demos), "docs" (R documentation), and "vignette" (vignettes).
OS_subdirs a character vector with the names of OS-specific subdirectories to possibly include in the listing of R code and documentation files. By default, the value of the environment variable R_OSTYPE, or if this is empty, the value of .Platform$OS.type, is used.

Details

file_ext returns the file (name) extensions (excluding the leading dot). (Only purely alphanumeric extensions are recognized.)
file_path_as_absolute turns a possibly relative file path absolute, performing tilde expansion if necessary. This is a wrapper for normalizePath. Currently, x must be a single existing path.
file_path_sans_ext returns the file paths without extensions (and the leading dot). (Only purely alphanumeric extensions are recognized.)
list_files_with_exts returns the paths or names of the files in directory dir with extension matching one of the elements of exts. Note that by default, full paths are returned, and that only visible files are used.
list_files_with_type returns the paths of the files in dir of the given ‘type’, as determined by the extensions recognized by R. When listing R code and documentation files, files in OS-specific subdirectories are included if present according to the value of OS_subdirs. Note that by default, full paths are returned, and that only visible files are used.

file.path, file.info, list.files
find_gs_cmd

Examples

```r
dir <- file.path(R.home(), "library", "stats")
list_files_with_exts(file.path(dir, "demo"), "R")
list_files_with_type(file.path(dir, "demo"), "demo") # the same
file_path_sans_ext(list.files(file.path(R.home("modules"))))
```

Description

Find a GhostScript executable in a cross-platform way.

Usage

```r
find_gs_cmd(gs_cmd = "")
```

Arguments

- **gs_cmd**
  - The name, full or partial path of a GhostScript executable.

Details

The details differ by platform.

On a Unix-alike, the GhostScript executable is usually called `gs`. The name (and possibly path) of the command is taken first from argument `gs_cmd` then from the environment variable `R_GSCMD` and default `gs`. This is then looked for on the system path and the value returned if a match is found.

On Windows, the name of the command is taken from argument `gs_cmd` then from the environment variables `R_GSCMD` and `GSC`. If neither of those produces a suitable command name, `gswin64c` and `gswin32c` are tried in turn. In all cases the command is looked for on the system PATH.

Note that on Windows (and some other OSes) there are separate GhostScript executables to display Postscript/PDF files and to manipulate them: this function looks for the latter.

Value

A character string giving the full path to a GhostScript executable if one was found, otherwise an empty string.

Examples

```r
## Not run:
## Suppose a Solaris system has GhostScript 9.00 on the path and
## 9.07 in /opt/csw/bin. Then one might set
Sys.setenv(R_GSCMD = "/opt/csw/bin/gs")

## End(Not run)
```
getDepList

Functions to Retrieve Dependency Information

Description

Given a dependency matrix, will create a DependsList object for that package which will include
the dependencies for that matrix, which ones are installed, which unresolved dependencies were
found online, which unresolved dependencies were not found online, and any R dependencies.

Usage

gDepList(depMtrx, instPkgs, recursive = TRUE, local = TRUE,
reduce = TRUE, lib.loc = NULL)
pkgDepends(pkg, recursive = TRUE, local = TRUE, reduce = TRUE,
lib.loc = NULL)

Arguments

depMtrx A dependency matrix as from package.dependencies
pkg The name of the package
instPkgs A matrix specifying all packages installed on the local system, as from
installed.packages
recursive Whether or not to include indirect dependencies
local Whether or not to search only locally
reduce Whether or not to collapse all sets of dependencies to a minimal value
lib.loc What libraries to use when looking for installed packages. NULL indicates all
library directories in the user’s .libPaths().

Details

The function pkgDepends is a convenience function which wraps getDepList and takes as input
a package name. It will then query installed.packages and also generate a dependency matrix,
calling getDepList with this information and returning the result.

These functions will retrieve information about the dependencies of the matrix, resulting in a
DependsList object. This is a list with four elements:

**Depends** A vector of the dependencies for this package.

**Installed** A vector of the dependencies which have been satisfied by the currently installed pack-
ages.

**Found** A list representing the dependencies which are not in Installed but were found online.
This list has element names which are the URLs for the repositories in which packages were
found and the elements themselves are vectors of package names which were found in the
respective repositories. If local = TRUE, the Found element will always be empty.

**R** Any R version dependencies.
If `recursive` is `TRUE`, any package that is specified as a dependency will in turn have its dependencies included (and so on), these are known as indirect dependencies. If `recursive` is `FALSE`, only the dependencies directly stated by the package will be used.

If `local` is `TRUE`, the system will only look at the user’s local install and not online to find unresolved dependencies.

If `reduce` is `TRUE`, the system will collapse the fields in the `dependsList` object such that a minimal set of dependencies are specified (for instance if there was ‘foo, foo (>= 1.0.0), foo (>= 1.3.0)’, it would only return ‘foo (>= 1.3.0)’).

**Value**

An object of class “`DependsList`”.

**Author(s)**

Jeff Gentry

**See Also**

`installFoundDepends`

**Examples**

```r
pkgDepends("tools", local = FALSE)
```

---

**getVignetteInfo**  
*Get information on installed vignettes.*

**Description**

This function gets information on installed vignettes.

**Usage**

```r
getVignetteInfo(package = NULL, lib.loc = NULL, all = TRUE)
```

**Arguments**

- **package**  
  Which package to look in, or NULL for all packages.
- **lib.loc**  
  Which library to look in.
- **all**  
  Whether to search all installed packages, or just attached packages.

**Value**

A matrix with columns:

- **Package**  
  the name of the package
- **Dir**  
  the directory where the package is installed
- **Topic**  
  the name of the vignette
- **File**  
  the base filename of the source of the vignette
- **Title**  
  the title of the vignette
- **R**  
  the tangled R source from the vignette
- **PDF**  
  the PDF or HTML file for display
Note

The last column of the result is named PDF for historical reasons, but it may contain a filename of a PDF or HTML document.

See Also

pkgVignettes is a similar function that can work on an uninstallled package.

Examples

gVignetteInfo("grid")

**HTMLheader**

Generate a standard HTML header for R help

Description

This function generates the standard HTML header used on R help pages.

Usage

```r
HTMLheader(title = "R", logo = TRUE, up = NULL,
           top = file.path(Rhome, "doc/html/index.html"),
           Rhome = "",
           css = file.path(Rhome, "doc/html/R.css"),
           headerTitle = paste("R::", title),
           outputEncoding = "UTF-8")
```

Arguments

- `title`: The title to display and use in the HTML headers. Should have had any HTML escaping already done.
- `logo`: Whether to display the R logo after the title.
- `up`: Which page (if any) to link to on the “up” button.
- `top`: Which page (if any) to link to on the “top” button.
- `Rhome`: A relative path to the R home directory. See the ‘Details’.
- `css`: The relative URL for the Cascading Style Sheet.
- `headerTitle`: The title used in the headers.
- `outputEncoding`: The declared encoding for the whole page.

Details

The up and top links should be relative to the current page. The Rhome path default works with dynamic help; for static help, a relative path (e.g., ‘./’) to it should be used.

Value

A character vector containing the lines of an HTML header which can be used to start a page in the R help system.
**HTMLlinks**

**Examples**

```r
cat(HTMLheader("This is a sample header"), sep="\n")
```

**Description**

Compute relative file paths for URLs to other package’s installed HTML documentation.

**Usage**

```r
findHTMLlinks(pkgDir = "", lib.loc = NULL, level = 0:2)
```

**Arguments**

- `pkgDir`: the top-level directory of an installed package. The default indicates no package.
- `lib.loc`: character vector describing the location of R library trees to scan: the default indicates `.libPaths()`.
- `level`: Which level(s) to include.

**Details**

`findHTMLlinks` tries to resolve links from one help page to another. It uses in decreasing priority

- The package in `pkgDir`: this is used when converting HTML help for that package (level 0).
- The base and recommended packages (level 1).
- Other packages found in the library trees specified by `lib.loc` in the order of the trees and alphabetically within a library tree (level 2).

**Value**

A named character vector of file paths, relative to the ‘html’ directory of an installed package. So these are of the form ‘""/somepkg/html/sometopic.html""’.

**Author(s)**

Duncan Murdoch, Brian Ripley
installFoundDepends

A function to install unresolved dependencies

Description

This function will take the Found element of a pkgDependsList object and attempt to install all of the listed packages from the specified repositories.

Usage

installFoundDepends(depPkgList, ...)

Arguments

depPkgList     A Found element from a pkgDependsList object
...            Arguments to pass on to install.packages

Details

This function takes as input the Found list from a pkgDependsList object. This list will have element names being URLs corresponding to repositories and the elements will be vectors of package names. For each element, install.packages is called for that URL to install all packages listed in the vector.

Author(s)

Jeff Gentry

See Also

pkgDepends, install.packages

Examples

## Set up a temporary directory to install packages to
tmp <- tempfile()
dir.create(tmp)

pDL <- pkgDepends("tools", local = FALSE)
installFoundDepends(pDL$Found, destdir = tmp)
**make_translations_pkg**  
*Package the Current Translations in the R sources*

**Description**  
A utility for R Core members to prepare a package of updated translations.

**Usage**  
```r  
make_translations_pkg(srcdir, outDir = ".", append = "-1")  
```

**Arguments**

- `srcdir`  
The R source directory.
- `outDir`  
The directory into which to place the prepared package.
- `append`  
The suffix for the package version number, e.g. 3.0.0-1 will be the default in R 3.0.0.

**Details**

This extracts the translations in a current R source distribution and packages them as a source package called `translations` which can be distributed on CRAN and installed by `update.packages`. This allows e.g. the translations shipped in R 3.x.y to be updated to those currently in ‘R-patched’, even by a user without administrative privileges. The package has a ‘depends’ field which restricts it to versions 3.x.* for a single x.

---

**md5sum**  
*Compute MD5 Checksums*

**Description**

Compute the 32-byte MD5 hashes of one or more files.

**Usage**  
```r  
md5sum(files)  
```

**Arguments**

- `files`  
character. The paths of file(s) whose contents are to be hashed.

**Details**

A MD5 ‘hash’ or ‘checksum’ or ‘message digest’ is a 128-bit summary of the file contents represented by 32 hexadecimal digits. Files with different MD5 sums are different; only very exceptionally (and usually with the intent to deceive) are those with the same sums different. On Windows all files are read in binary mode (as the md5sum utilities there do): on other OSes the files are read in the default mode (almost always text mode where there is more than one). MD5 sums are used as a check that R packages have been unpacked correctly and not subsequently modified.
Value

A character vector of the same length as `files`, with names equal to `files`. The elements will be NA for non-existent or unreadable files, otherwise a 32-character string of hexadecimal digits.

Source

The underlying C code was written by Ulrich Drepper and extracted from a 2001 release of glibc.

`checkMD5sums`

Examples

```r
as.vector(md5sum(dir(R.home(), pattern = "COPY", full.names = TRUE)))
```

package.dependencies  Check Package Dependencies

Description

Parses and checks the dependencies of a package against the currently installed version of R (and other packages).

Usage

```r
package.dependencies(x, check = FALSE,
  depLevel =
  c("Depends", "Imports", "Suggests"))
```

Arguments

- `x` A matrix of package descriptions as returned by `available.packages`.
- `check` If TRUE, return logical vector of check results. If FALSE, return parsed list of dependencies.
- `depLevel` Whether to look for `Depends` or `Suggests` level dependencies.

Details

Currently we only check if the package conforms with the currently running version of R. In the future we might add checks for inter-package dependencies.

See Also

`update.packages`
package_dependencies  Compositions on the Dependency Hierarchy of Packages

Description

Find (recursively) dependencies or reverse dependencies of packages.

Usage

package_dependencies(packages = NULL, db,
  which = c("Depends", "Imports", "LinkingTo"),
  recursive = FALSE, reverse = FALSE)

Arguments

packages  a character vector of package names.
db  character matrix as from available.packages(), or data frame variants thereof. Alternatively, a package database like the one available from http://cran.r-project.org/web/packages/packages.rds.
which  a character vector listing the types of dependencies, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Character string "all" is shorthand for that vector, character string "most" for the same vector without "Enhances".
recursive  logical: should (reverse) dependencies of (reverse) dependencies (and so on) be included?
reverse  logical: if FALSE (default), regular dependencies are calculated, otherwise reverse dependencies.

Value

Named list with one element for each package in argument packages, each consists of a character vector naming the (recursive) (reverse) dependencies of that package.

For given packages which are not found in the db, NULL entries are returned, as opposed to character(0) entries which indicate no dependencies.

See Also

dependsonpkgs, and package_dependencies for checking dependencies

Examples

## Not run:
pdb <- available.packages()
deps <- package_dependencies(packages = "MASS", pdb,
  which = c("Depends", "Imports", "LinkingTo", "Suggests"),
  recursive = TRUE, reverse = TRUE)
length(deps$MASS)

## End(Not run)
These experimental functions work with a subset of LaTeX code.

Description

The `parseLatex` function parses LaTeX source, producing a structured object; `deparseLatex` reverses the process. The `latexToUtf8` function takes a LaTeX object, and processes a number of different macros to convert them into the corresponding UTF-8 characters.

Usage

```r
parseLatex(text, filename = deparse(substitute(text)),
            verbose = FALSE,
            verbatim = c("verbatim", "verbatimx",
                          "Input", "Output"))
```

```r
deparseLatex(x, dropBraces = FALSE)
```

```r
latexToUtf8(x)
```

Arguments

- **text**: A character vector containing LaTeX source code.
- **filename**: A filename to use in syntax error messages.
- **verbose**: If TRUE, print debug error messages.
- **verbatim**: A character vector containing the names of LaTeX environments holding verbatim text.
- **x**: A "LaTeX" object.
- **dropBraces**: Drop unnecessary braces when displaying a "LaTeX" object.

Details

The parser does not recognize all legal LaTeX code, only relatively simple examples. It does not associate arguments with macros, that needs to be done after parsing, with knowledge of the definitions of each macro. The main intention for this function is to process simple LaTeX code used in bibliographic references, not fully general LaTeX documents.

Verbose text is allowed in two forms: the \verb macro (with single character delimiters), and environments whose names are listed in the `verbatim` argument.

Value

The `parseLatex()` function returns a recursive object of class "LaTeX". Each of the entries in this object will have a "latex_tag" attribute identifying its syntactic role.

The `deparseLatex()` function returns a single element character vector, possibly containing embedded newlines.

The `latexToUtf8()` function returns a modified version of the "LaTeX" object that was passed to it.

Author(s)

Duncan Murdoch
**parse_Rd**

**Parse an Rd file**

**Description**

This function reads an R documentation (Rd) file and parses it, for processing by other functions.

**Usage**

```r
parse_Rd(file, srcfile = NULL, encoding = "unknown",
         verbose = FALSE, fragment = FALSE, warningCalls = TRUE)
```

### S3 method for class 'Rd'

```r
print(x, deparse = FALSE, ...)
```

### S3 method for class 'Rd'

```r
as.character(x, deparse = FALSE, ...)
```

**Arguments**

- **file**: A filename or text-mode connection. At present filenames work best.
- **srcfile**: NULL, or a "srcfile" object. See the ‘Details’ section.
- **encoding**: Encoding to be assumed for input strings.
- **verbose**: Logical indicating whether detailed parsing information should be printed.
- **fragment**: Logical indicating whether file represents a complete Rd file, or a fragment.
- **warningCalls**: Logical: should parser warnings include the call?
- **x**: An object of class Rd.
- **deparse**: If TRUE, attempt to reinstate the escape characters so that the resulting characters will parse to the same object.
- **...**: Further arguments to be passed to or from other methods.

**Details**

This function parses ‘Rd’ files according to the specification given in [http://developer.r-project.org/parseRd.pdf](http://developer.r-project.org/parseRd.pdf).

It generates a warning for each parse error and attempts to continue parsing. In order to continue, it is generally necessary to drop some parts of the file, so such warnings should not be ignored.

Files without a marked encoding are by default assumed to be in the native encoding. An alternate default can be set using the encoding argument. All text in files is translated to the UTF-8 encoding in the parsed object.

**Examples**

```r
latex <- parseLatex("fa\c(c)ile")
deparseLatex(latexToUtf8(latex))
```
pskill

Kill a Process

Description

pskill sends a signal to a process, usually to terminate it.

Usage

```
pskill(pid, signal = SIGTERM)
```

SIGHUP
SIGINT
SIGQUIT
SIGKILL
SIGTERM
SIGSTOP
SIGTSTP
SIGCHLD
SIGUSR1
SIGUSR2

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| pid      | positive integers: one or more process IDs as returned by `Sys.getpid`.
| signal   | integer, most often one of the symbolic constants. |
Details

Signals are a C99 concept, but only a small number are required to be supported (of those listed, only SIGINT and SIGTERM). They are much more widely used on POSIX operating systems (which should define all of those listed here), which also support a kill system call to send a signal to a process, most often to terminate it. Function pskill provides a wrapper: it silently ignores invalid values of its arguments, including zero or negative pids.

In normal use on a Unix-alike, Ctrl-C sends SIGINT, Ctrl-\ sends SIGQUIT and Ctrl-Z sends SIGTSTP: that and SIGSTOP suspend a process which can be resumed by SIGCONT.

The signals are small integers, but the actual numeric values are not standardized (and most do differ between OSes). The SIG* objects contain the appropriate integer values for the current platform (or NA_INTEGER if the signal is not defined).

Only SIGINT and SIGKILL will be defined on Windows, and pskill will always use the Windows system call TerminateProcess.

Value

A logical vector of the same length as pid, TRUE (for success) or FALSE, invisibly.

See Also

Package parallel has several means to launch child processes which record the process IDs.

Examples

```r
## Not run:
pskill(c(237, 245), SIGKILL)
## End(Not run)
```

psnice Get or Set the Priority (Niceness) of a Process

Description

Get or set the ‘niceness’ of the current process, or one or more other processes.

Usage

```
psnice(pid = Sys.getpid(), value = NA_integer_)
```

Arguments

- **pid**: positive integers: the process IDs of one or more processes: defaults to the R session process.
- **value**: The niceness to be set, or NA for an enquiry.
### Details

POSIX operating systems have a concept of process priorities, usually from 0 to 39 (or 40) with 20 being a normal priority and (somewhat confusingly) larger numeric values denoting lower priority. To add to the confusion, there is a ‘niceness’ value, the amount by which the priority numerically exceeds 20 (which can be negative). Processes with high niceness will receive less CPU time than those with normal priority. On some OSes, processes with niceness +19 are only run when the system would otherwise be idle.

On many OSes utilities such as `top` report the priority and not the niceness. Niceness is used by the utility `/usr/bin/renice`: `/usr/bin/nice` (and `/usr/bin/renice -n`) specifies an increment in niceness.

Only privileged users (usually super-users) can lower the niceness.

Windows has a slightly different concept of ‘priority classes’. We have mapped the idle priority to niceness 19, ‘below normal’ to 15, normal to 0, ‘above normal’ to -5 and ‘realtime’ to -10. Unlike Unix-alikes, a non-privileged user can increase the priority class on Windows (but using ‘realtime’ is inadvisable).

### Value

An integer vector of previous niceness values, `NA` if unknown for any reason.

### See Also

Various functions in package `parallel` create child processes whose priority may need to be changed. `pskill`.

### QC Checks for R Code and/or Documentation

#### Description

Functions for performing various quality checks.

#### Usage

```r
checkDocFiles(package, dir, lib.loc = NULL)
checkDocStyle(package, dir, lib.loc = NULL)
checkReplaceFuns(package, dir, lib.loc = NULL)
checkS3methods(package, dir, lib.loc = NULL)
```

#### Arguments

- **package**: a character string naming an installed package.
- **dir**: a character string specifying the path to a package’s root source directory. This should contain the subdirectories ‘R’ (for R code) and ‘man’ with R documentation sources (in Rd format). Only used if `package` is not given.
- **lib.loc**: a character vector of directory names of R libraries, or `NULL`. The default value of `NULL` corresponds to all libraries currently known. The specified library trees are used to search for `package`.

---
Details

checkDocFiles checks, for all Rd files in a package, whether all arguments shown in the usage sections of the Rd file are documented in its arguments section. It also reports duplicated entries in the arguments section, and ‘over-documented’ arguments which are given in the arguments section but not in the usage. Note that the match is for the usage section and not a possibly existing synopsis section, as the usage is what gets displayed.

checkDocStyle investigates how (S3) methods are shown in the usages of the Rd files in a package. It reports the methods shown by their full name rather than using the Rd \method markup for indicating S3 methods. Earlier versions of R also reported about methods shown along with their generic, which typically caused problems for the documentation of the primary argument in the generic and its methods. With \method now being expanded in a way that class information is preserved, joint documentation is no longer necessarily a problem. (The corresponding information is still contained in the object returned by checkDocStyle.)

checkReplaceFuns checks whether replacement functions or S3/S4 replacement methods in the package R code have their final argument named value.

checkS3methods checks whether all S3 methods defined in the package R code have all arguments of the corresponding generic, with positional arguments of the generics in the same positions for the method. As an exception, the first argument of a formula method may be called formula even if this is not the name used by the generic. The rules when ... is involved are subtle: see the source code. Functions recognized as S3 generics are those with a call to UseMethod in their body, internal S3 generics (see \InternalMethods), and S3 group generics (see \Math). Possible dispatch under a different name is not taken into account. The generics are sought first in the given package, then in the base package and (currently) the packages graphics, stats, and utils added in R 1.9.0 by splitting the former base, and, if an installed package is tested, also in the loaded namespaces/packages listed in the package’s ‘DESCRIPTION’ Depends field.

If using an installed package, the checks needing access to all R objects of the package will load the package (unless it is the base package), after possibly detaching an already loaded version of the package.

Value

The functions return objects of class the same as the respective function names containing the information about problems detected. There are print methods for nicely displaying the information contained in such objects.

Rd2HTML

Rd Converters

Description

These functions take the output of the parse_Rd function and produce a help page from it. As they are mainly intended for internal use, their interfaces are subject to change.

Usage

Rd2HTML(Rd, out = "", package = "", defines = .Platform$OS.type,
      Links = NULL, Links2 = NULL,
      stages = "render", outputEncoding = "UTF-8",
      dynamic = FALSE, no_links = FALSE, fragment = FALSE,
stylesheets = "R.css", ...)

Rd2txt(Rd, out = "", package = "", defines = .Platform$OS.type,
    stages = "render", outputEncoding = "",
    fragment = FALSE, options, ...)  

Rd2latex(Rd, out = "", defines = .Platform$OS.type,
    stages = "render", outputEncoding = "ASCII",
    fragment = FALSE, ..., writeEncoding = TRUE)

Rd2ex(Rd, out = "", defines = .Platform$OS.type,
    stages = "render", outputEncoding = "UTF-8",
    commentDontrun = TRUE, ...)

Arguments

Rd a filename or Rd object to use as input.
out a filename or connection object to which to write the output.
package the package to list in the output.
defines string(s) to use in #ifdef tests.
stages at which stage ("build", "install", or "render") should \Sexpr macros be executed? See the notes below.
outputEncoding see the ‘Encodings’ section below.
dynamic logical: set links for render-time resolution by dynamic help system.
no_links logical: suppress hyperlinks to other help topics. Used by \ CMD Rdconv.
fragment logical: should fragments of Rd files be accepted? See the notes below.
stylesheet character: a URL for a stylesheet to be used in the header of the HTML output page.
Links, Links2 NULL or a named (by topics) character vector of links, as returned by findHTMLlinks.
options An optional named list of options to pass to Rd2txt_options.
... additional parameters to pass to parse_Rd when Rd is a filename.
writeEncoding should \inputencoding lines be written in the file for non-ASCII encodings?
commentDontrun should \dontrun sections be commented out?

Details

These functions convert help documents: Rd2HTML produces HTML, Rd2txt produces plain text,
Rd2latex produces LaTeX. Rd2ex extracts the examples in the format used by example and \ R utilities.

Each of the functions accepts a filename for an Rd file, and will use \ parse_Rd to parse it before applying the conversions or checks.

The difference between arguments Link and Link2 is that links are looked in them in turn, so lazy-evaluation can be used to only do a second-level search for links if required.

Note that the default for Rd2latex is to output ASCII, including using the second option of \enc markup. This was chosen because use of UTF-8 in LaTeX requires version ‘2005/12/01’ or later, and even with that version the coverage of UTF-8 glyphs is not extensive (and not even as complete as Latin-1).
Rd2txt will format text paragraphs to a width determined by width, with appropriate margins. The default is to be close to the rendering in versions of R < 2.10.0.

Rd2txt will use directional quotes (see sQuote) if option "useFancyQuotes" is true (the default) and the current encoding is UTF-8.

Various aspects of formatting by Rd2txt are controlled by the options argument, documented with the Rd2txt_options function. Changes made using options are temporary, those made with Rd2txt_options are persistent.

When fragment = TRUE, the Rd file will be rendered with no processing of \Sexpr elements or conditional defines using #ifdef or #ifndef. Normally a fragment represents text within a section, but if the first element of the fragment is a section macro, the whole fragment will be rendered as a series of sections, without the usual sorting.

Value

These functions are executed mainly for the side effect of writing the converted help page. Their value is the name of the output file (invisibly). For Rd2latex, the output name is given an attribute "latexEncoding" giving the encoding of the file in a form suitable for use with the LaTeX ‘inputenc’ package.

Encodings

Rd files are normally intended to be rendered on a wide variety of systems, so care must be taken in the encoding of non-ASCII characters. In general, any such encoding should be declared using the ‘encoding’ section for there to be any hope of correct rendering.

For output, the outputEncoding argument will be used: outputEncoding = "" will choose the native encoding for the current system.

If the text cannot be converted to the outputEncoding, byte substitution will be used (see icnv): Rd2latex and Rd2ex give a warning.

Note

The \Sexpr macro is a new addition to Rd files. It includes R code that will be executed at one of three times: build time (when a package’s source code is built into a tarball), install time (when the package is installed or built into a binary package), and render time (when the man page is converted to a readable format).

For example, this man page was:

1. built on 2015-02-14 at 05:33:26,
2. installed on 2015-02-14 at 05:33:26, and
3. rendered on 2015-02-14 at 05:36:42.

Examples

```r
## Not run:
## Simulate install and rendering of this page in HTML and text format:

Rd <- file.path("src/library/tools/man/Rd2HTML.Rd")

outfile <- tempfile(fileext = ".html")
browseURL(Rd2HTML(Rd, outfile, package = "tools",
                 stages = c("install", "render")))

outfile <- tempfile(fileext = ".txt")
file.show(Rd2txt(Rd, outfile, package = "tools",
               stages = c("install", "render")))

checkRd(Rd) # A stricter test than Rd2HTML uses

## End(Not run)
```

---

Rd2txt_options  
Set formatting options for text help

**Description**

This function sets various options for displaying text help.

**Usage**

Rd2txt_options(...)  

**Arguments**

...  
A list containing named options, or options passed as individual named arguments. See below for currently defined ones.

**Details**

This function persistently sets various formatting options for the Rd2txt function which is used in displaying text format help. Currently defined options are:

- **width** (default 80): The width of the output page.
- **minIndent** (default 10): The minimum indent to use in a list.
- **extraIndent** (default 4): The extra indent to use in each level of nested lists.
- **sectionIndent** (default 5): The indent level for a section.
- **sectionExtra** (default 2): The extra indentation for each nested section level.
- **itemBullet** (default "* ", with the asterisk replaced by a Unicode bullet in UTF-8 and most Windows locales): The symbol to use as a bullet in itemized lists.
- **enumFormat** : A function to format item numbers in enumerated lists.
- **showURLs** (default FALSE): Whether to show URLs when expanding \href tags.
- **code_quote** (default TRUE): Whether to render `code` and similar with single quotes.
- **underline_titles** default TRUE): Whether to render section titles with underlines (via backspacing).
Value

If called with no arguments, returns all option settings in a list. Otherwise, it changes the named
settings and invisibly returns their previous values.

Rd2txt_options()

Rdiff

Description

Given two R output files, compute differences ignoring headers, footers and some other differences.

Usage

Rdiff(from, to, useDiff = FALSE, forEx = FALSE,
nullPointers = TRUE, Log = FALSE)

Arguments

from, to  filepaths to be compared
useDiff  should diff always be used to compare results?
forEx  logical: extra pruning for ‘~.Rout’ files to exclude the header.
nullPointers  logical: should the displayed addresses of pointers be set to 0x00000000 before
comparison?
Log  logical: should the returned value include a log of differences found?
Details

The R startup banner and any timing information from R CMD BATCH are removed from both files, together with lines about loading packages. UTF-8 fancy quotes (see sQuote) and on Windows, Windows' so-called 'smart quotes', are mapped to a simple quote. Addresses of environments, compiled bytecode and other exotic types expressed as hex addresses (e.g., <environment: 0x12345678>) are mapped to 0x00000000. The files are then compared line-by-line. If there are the same number of lines and useDiff is false, a simple diff -b -like display of differences is printed (which ignores trailing spaces and differences in numbers of consecutive spaces), otherwise diff -bw is called on the edited files. (This tries to ignore all differences in whitespace: note that flag ‘-w’ is not required by POSIX but is supported by GNU, Solaris and FreeBSD versions.)

This can compare uncompressed PDF files, ignoring differences in creation and modification dates.

Value

If Log is true, a list with components status (see below) and out, a character vector of descriptions of differences, possibly of zero length.

Otherwise, a status indicator, 0L if and only if no differences were found.

See Also

The shell script run as R CMD Rdiff.

---

Rdindex Generate Index from Rd Files

Description

Print a 2-column index table with names and titles from given R documentation files to a given output file or connection. The titles are nicely formatted between two column positions (typically 25 and 72, respectively).

Usage

rdindex(RdFiles, outFile = "", type = NULL,
          width = 0.9 *getOption("width"), indent = NULL)

Arguments

RdFiles a character vector specifying the Rd files to be used for creating the index, either by giving the paths to the files, or the path to a single directory with the sources of a package.

outFile a connection, or a character string naming the output file to print to. "" (the default) indicates output to the console.

type a character string giving the documentation type of the Rd files to be included in the index, or NULL (the default). The type of an Rd file is typically specified via the \docType tag; if type is "data", Rd files whose only keyword is datasets are included as well.

width a positive integer giving the target column for wrapping lines in the output.

indent a positive integer specifying the indentation of the second column. Must not be greater than width/2, and defaults to width/3.
Details

If a name is not a valid alias, the first alias (or the empty string if there is none) is used instead.

RdTextFilter

Select text in an Rd file.

Description

This function blanks out all non-text in an Rd file, for spell checking or other uses.

Usage

RdTextFilter(ifile, encoding = "unknown", keepSpacing = TRUE, drop = character(), keep = character())

Arguments

ifile An input file specified as a filename or connection, or an "Rd" object from parse_Rd.
encoding An encoding name to pass to parse_Rd.
keepSpacing Whether to try to leave the text in the same lines and columns as in the original file.
drop Additional sections of the Rd to drop.
keep Sections of the Rd file to keep.

Details

This function parses the Rd file, then walks through it, element by element. Items with tag "TEXT" are kept in the same position as they appeared in the original file, while other parts of the file are replaced with blanks, so a spell checker such as aspell can check only the text and report the position in the original file. (If keepSpacing is FALSE, blank filling will not occur, and text will not be output in its original location.)

By default, the tags \S3method, \S4method, \command, \docType, \email, \encoding, \file, \key- word, \link, \linkS4class, \method, \pkg, and \var are skipped. Additional tags can be skipped by listing them in the drop argument; listing tags in the keep argument will stop them from being skipped. It is also possible to keep any of the c("RCODE", "COMMENT", "VERB") tags, which correspond to R-like code, comments, and verbatim text respectively, or to drop "TEXT".

Value

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Rd file.

Note

The filter attempts to merge text elements into single words when markup in the Rd file is used to highlight just the start of a word.

aspell, for which this is an acceptable filter.

Rd Utilities

Description

Utilities for computing on the information in Rd objects.

Usage

Rd_db(package, dir, lib.loc = NULL)

Arguments

package a character string naming an installed package.
dir a character string specifying the path to a package’s root source directory. This should contain the subdirectory ‘man’ with R documentation sources (in Rd format). Only used if package is not given.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.

Details

Rd_db builds a simple database of all Rd objects in a package, as a list of the results of running parse_Rd on the Rd source files in the package and processing platform conditionals.

See Also

parse_Rd

Examples

## Build the Rd db for the (installed) base package.
db <- Rd_db("base")

## Keyword metadata per Rd object.
keywords <- lapply(db, tools::Rd_get_metadata, "keyword")
## Tabulate the keyword entries.
kw_table <- sort(table(unlist(keywords)))
## The 5 most frequent ones:
rev(kw_table)[1:5]
## The "most informative" ones:
kw_table[kw_table == 1]

## Concept metadata per Rd file.
concepts <- lapply(db, tools::Rd_get_metadata, "concept")
## How many files already have \concept metadata?
sum(sapply(concepts, length) > 0)
## How many concept entries altogether?
length(unlist(concepts))
**read.00Index**

*Read 00Index-style Files*

**Description**

Read item/description information from ‘00Index’-like files. Such files are description lists rendered in tabular form, and currently used for the ‘INDEX’ and ‘demo/00Index’ files of add-on packages.

**Usage**

read.00Index(file)

**Arguments**

file  
the name of a file to read data values from. If the specified file is “”, then input is taken from the keyboard (in this case input can be terminated by a blank line). Alternatively, file can be a connection, which will be opened if necessary, and if so closed at the end of the function call.

**Value**

A character matrix with 2 columns named “Item” and “Description” which hold the items and descriptions.

**See Also**

`formatDL` for the inverse operation of creating a 00Index-style file from items and their descriptions.

---

**showNonASCII**

*Pick Out Non-ASCII Characters*

**Description**

This function prints elements of a character vector which contain non-ASCII bytes, printing such bytes as a escape like ‘<fc>’.

**Usage**

showNonASCII(x)

showNonASCII(file)

**Arguments**

x  
a character vector.

file  
path to a file.
Details

This was originally written to help detect non-portable text in files in packages.

It prints all element of \( x \) which contain non-ASCII characters, preceded by the element number and with non-ASCII bytes highlighted via `iconv(sub = "byte")`.

Value

The elements of \( x \) containing non-ASCII characters will be returned invisibly.

Examples

```r
cat(c("fa\xE7ile test of showNonASCII():","\"\details\"",
\"This is a good line",
\"This has an \x{cf}mlaut in it.",
\"OK again.\",
\")")
f <- tempfile()
cat(out, file = f, sep = "\n")
showNonASCIIfile(f)
unlink(f)
```

Description

This function starts the internal help server, so that HTML help pages are rendered when requested.

Usage

```r
startDynamicHelp(start = TRUE)
```

Arguments

- `start` logical: whether to start or shut down the dynamic help system.

Details

This function starts the internal HTTP server, which runs on the loopback interface (127.0.0.1). If `options("help.port")` is set to a vector of integer values, `startDynamicHelp` will try those ports in order; otherwise, it tries up to 10 random ports to find one not in use. It can be disabled by setting the environment variable `R_DISABLE_HTTPD` to a non-empty value.

`startDynamicHelp` is called by functions that need to use the server, so would rarely be called directly by a user.

Note that `options(help_type = "html")` must be set to actually make use of HTML help, although it might be the default for an R installation.

If the server cannot be started or is disabled, `help.start` will be unavailable and requests for HTML help will give text help (with a warning).
The browser in use does need to be able to connect to the loopback interface: occasionally it is set to use a proxy for HTTP on all interfaces, which will not work – the solution is to add an exception for 127.0.0.1.

Value

The chosen port number is returned invisibly (which will be 0 if the server has been stopped).

See Also

`help.start` and `help(help_type = "html")` will attempt to start the HTTP server if required, `Rd2HTML` is used to render the package help pages.

---

**SweaveTeXFilter**  
*Strip R code out of Sweave file*

**Description**

This function blanks out code chunks and Noweb markup in an Sweave input file, for spell checking or other uses.

**Usage**

```r
SweaveTeXFilter(ifile, encoding = "unknown")
```

**Arguments**

- `ifile`  
  Input file or connection.
- `encoding`  
  Text encoding to pass to `readLines`.

**Details**

This function blanks out all Noweb markup and code chunks from an Sweave input file, leaving behind the LaTeX source, so that a LaTeX-aware spelling checker can check it and report errors in their original locations.

**Value**

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Sweave input file.

**Author(s)**

Duncan Murdoch

**See Also**

`aspell`, for which this is used with `filter = "Sweave"`. 
testInstalledPackage  Test Installed Packages

Description

These functions allow an installed package to be tested, or all base and recommended packages.

Usage

```r
testInstalledPackage(pkg, lib.loc = NULL, outDir = ".",
                    types = c("examples", "tests", "vignettes"),
                    srcdir = NULL, Ropts = "")

testInstalledPackages(outDir = ".", errorsAreFatal = TRUE,
                        scope = c("both", "base", "recommended"),
                        types = c("examples", "tests", "vignettes"),
                        srcdir = NULL, Ropts = "")

testInstalledBasic(scope = c("basic", "devel", "both"))
```

Arguments

- `pkg`  
  name of an installed package.
- `lib.loc`  
  library path(s) in which to look for the package. See `library`.
- `outDir`  
  the directory into which to write the output files: this should already exist.
- `types`  
  type(s) of tests to be done.
- `errorsAreFatal`  
  logical: should testing terminate at the first error?
- `srcdir`  
  Optional directory to look for .save files.
- `Ropts`  
  Additional options such as `"-d valgrind"` to be passed to R CMD BATCH when running examples or tests.
- `...`  
  additional arguments use when preparing the files to be run, e.g. `commentDontrun` and `commentDonttest`.
- `scope`  
  Which set(s) should be tested?

Details

These tests depend on having the package example files installed (which is the default). If package-specific tests are found in a ‘tests’ directory they can be tested: these are not installed by default, but will be if R CMD INSTALL --install-tests was used. Finally, the R code in any vignettes can be extracted and tested.

Package tests are run in a ‘pkg-tests’ subdirectory of ‘outDir’, and leave their output there.

testInstalledBasic runs the basic tests, if installed. This should be run with LC_COLLATE=C set: the function tries to set this by it may not work on all OSes. For non-English locales it may be desirable to set environment variables LANGUAGE to ‘en’ and LC_TIME to ‘C’ to reduce the number of differences from reference results.

Except on Windows, if the environment variable TEST_MC_CORES is set to an integer greater than one, testInstalledPackages will run the package tests in parallel using its value as the maximum number of parallel processes.
The package-specific tests for the base and recommended packages are not normally installed, but 
make install-tests is provided to do so (as well as the basic tests).

Value
Invisibly 0L for success, 1L for failure.

---

**texi2dvi**

Compile LaTeX Files

**Description**
Run latex and bibtex until all cross-references are resolved and create either a dvi or a PDF file.

**Usage**

```r
texi2dvi(file, pdf = FALSE, clean = FALSE, quiet = TRUE,
         texi2dvi = getOption("texi2dvi"),
         texinputs = NULL, index = TRUE)

texi2pdf(file, clean = FALSE, quiet = TRUE,
         texi2dvi = getOption("texi2dvi"),
         texinputs = NULL, index = TRUE)
```

**Arguments**

- **file** character. Name of LaTeX source file.
- **pdf** logical. If TRUE, a PDF file is produced instead of the default dvi file (texi2dvi command line option ‘--pdf’).
- **clean** logical. If TRUE, all auxiliary files created during the conversion are removed.
- **quiet** logical. No output unless an error occurs. Ignored if emulation (see the texi2dvi argument) is used.
- **texi2dvi** character (or NULL). Script or program used to compile a TeX file to dvi or PDF, respectively. The default (selected by "" or NULL) is to look for an executable on the path and otherwise emulate the script with system calls.
- **texinputs** NULL or a character vector of paths to add to the LaTeX and bibtex input search paths.
- **index** logical: should indices be prepared?

**Details**

texi2pdf is a wrapper for the common case of texi2dvi(pdf = TRUE).

Despite the name, this is used in R to compile LaTeX files, specifically those generated from vignettes. It ensures that the ‘R_HOME/share/texmf’ directory is in the TEXINPUTS path, so R style files such as ‘Sweave’ and ‘Rd’ will be found. The TeX search path used is first the existing TEXINPUTS setting (or the current directory if unset), then elements of texinputs, then ‘R_HOME/share/texmf’ and finally the default path. Analogous changes are made to BIBINPUTS and BSTINPUTS settings.
MiKTeX has a `texi2dvi` executable but no other Windows TeX installation that we know of does, so emulation is used on e.g. TeXLive installations on Windows.

Occasionally indices contain special characters which cause indexing to fail (particularly when using the `hyperref` LaTeX package) even on valid input. The argument `index = FALSE` is provided to allow package manuals to be made when this happens: it uses emulation.

**Value**

Invisible NULL. Used for the side effect of creating a dvi or PDF file in the current working directory (and maybe other files, especially if `clean = FALSE`).

**Note**

There are various versions of the `texi2dvi` script on Unix-alikes and quite a number of bugs have been seen, some of which this R wrapper works around.

One that was present with `texi2dvi` version 4.8 (as supplied on OS X) is that it will not work correctly for paths which contain spaces, nor if the absolute path to a file would contain spaces.

The three possible approaches all have their quirks. For example the Unix-alike `texi2dvi` script removes ancillary files that already exist but the other two approaches do not (and may get confused by such files).

Where supported (`texi2dvi` 5.x and `texify`), option `--max-iterations=20` is used to avoid infinite retries.

**Author(s)**

Originally Achim Zeileis but largely rewritten by R-core.

---

**toHTML**

*Display an object in HTML.*

**Description**

This generic function generates a complete HTML page from an object.

**Usage**

```
toHTML(x, ...) # S3 method for class 'packageIQR'
toHTML(x, ...) # S3 method for class 'news_db'
toHTML(x, ...)
```

**Arguments**

- `x` An object to display.
- `...` Optional parameters for methods; the "packageIQR" and "news_db" methods pass these to `HTMLheader`. 
Value

A character vector to display the object x. The "packageIQR" method is designed to display lists in the R help system.

See Also

HTMLheader

Examples

cat(toHTML(demo(package = "base")), sep = "\n")

**tools-deprecated**

*Deprecated Objects in Package tools*

Description

The functions or variables listed here are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

See Also

Deprecation, Defunct

**toRd**

*Generic function to convert object to a fragment of Rd code.*

Description

Methods for this function render their associated classes as a fragment of Rd code, which can then be rendered into text, HTML, or LaTeX.

Usage

toRd(obj, ...)

## S3 method for class 'bibentry'
toRd(obj, style = NULL, ...)

Arguments

- **obj**: The object to be rendered.
- **style**: The style to be used in converting a bibentry object.
- **...**: Additional arguments used by methods.

Details

See bibstyle for a discussion of styles. The default style = NULL value gives the default style.
undoc

Find Undocumented Objects

Description

Finds the objects in a package which are undocumented, in the sense that they are visible to the user (or data objects or S4 classes provided by the package), but no documentation entry exists.

Usage

undoc(package, dir, lib.loc = NULL)

Arguments

package a character string naming an installed package.
dir a character string specifying the path to a package’s root source directory. This must contain the subdirectory ‘man’ with R documentation sources (in Rd format), and at least one of the ‘r’ or ‘data’ subdirectories with R code or data objects, respectively.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.

Details

This function is useful for package maintainers mostly. In principle, all user-level R objects should be documented.

The base package is special as it contains the primitives and these do not have definitions available at code level. We provide equivalent closures in environments .ArgsEnv and .GenericArgsEnv in the base package that are used for various purposes: undoc(“base”) checks that all the primitives that are not language constructs are prototyped in those environments and no others are.

Value

An object of class "undoc" which is a list of character vectors containing the names of the undocumented objects split according to documentation type.

There is a print method for nicely displaying the information contained in such objects.

See Also

codoc, QC

Examples

undoc("tools") # Undocumented objects in 'tools'
Prepare Translations for a Package

Description

Prepare the ‘po’ directory of a package and compile and install the translations.

Usage

update_pkg_po(pkgdir, pkg = NULL, version = NULL, copyright, bugs)

Arguments

pkgdir  The path to the package directory.
pkg     The package name: if NULL it is read from the package’s ‘DESCRIPTION’ file.
version The package version: if NULL it is read from the package’s ‘DESCRIPTION’ file.
copyright, bugs
           optional character strings for the ‘Copyright’ and ‘Report-Msgid-Bugs-To’
           details in the template files.

Details

This performs a series of steps to prepare or update messages in the package.

- If the package sources do not already have a ‘po’ directory, one is created.
- xgettextRp®t is called to create/update a file ‘po/R-pkgname.pot’ containing the translatable messages in the package.
- All existing files in directory po with names ‘R-lang.po’ are updated from ‘R-pkgname.pot’. checkPoFile is called on the updated file, and if there are no problems the file is compiled and installed under ‘inst/po’.
- In a UTF-8 locale, a ‘translation’ ‘en@quotNp®’ is created with UTF-8 directional quotes, compiled and installed under ‘inst/po’.
- The remaining steps are done only if file ‘po/pkgname.pot’ already exists. The ‘src/.*(c,cc,cpp,m,mm)’ files in the package are examined to create a file ‘po/pkgname.pot’ containing the translatable messages in the C/C++ files. If there is a src/windows directory, files within it are also examined.
- All existing files in directory po with names ‘lang.po’ are updated from ‘pkgname.pot’. checkPoFile is called on the updated file, and if there are no problems the file is compiled and installed under ‘inst/po’.
- In a UTF-8 locale, a ‘translation’ ‘en@quotNp®’ is created with UTF-8 directional quotes, compiled and installed under ‘inst/po’.

Note that C/C++ messages are not automatically prepared for translation as they need to be explicitly marked for translation in the source files. Once that has been done, create an empty file ‘po/pkgname.pot’ in the package sources and run this function again.

pkg = “base” is special (and for use by R developers only): the C files are not in the package directory but in the main sources.
System requirements

This function requires the following tools from the GNU gettext-tools: xgettext, msgmerge, msgfmt, msginit and msgconv. These are part of most Linux distributions and easily compiled from the sources on Unix-alikes (including OS X). Pre-compiled versions for Windows are available in http://www.stats.ox.ac.uk/pub/Rtools/goodies/gettext-tools.zip.

It will probably not work correctly for en@quot translations except in a UTF-8 locale, so these are skipped elsewhere.

See Also

xgettext2pot.

vignetteDepends  Retrieve Dependency Information for a Vignette

Description

Given a vignette name, will create a DependsList object that reports information about the packages the vignette depends on.

Usage

vignetteDepends(vignette, recursive = TRUE, reduce = TRUE,
local = TRUE, lib.loc = NULL)

Arguments

vignette  The path to the vignette source
recursive  Whether or not to include indirect dependencies
reduce    Whether or not to collapse all sets of dependencies to a minimal value
local     Whether or not to search only locally
lib.loc   What libraries to search in locally

Details

If recursive is TRUE, any package that is specified as a dependency will in turn have its dependencies included (and so on), these are known as indirect dependencies. If recursive is FALSE, only the dependencies directly named by the vignette will be used.

If local is TRUE, the system will only look at the user’s local machine and not online to find dependencies.

If reduce is TRUE, the system will collapse the fields in the DependsList object such that a minimal set of dependencies are specified (for instance if there was ‘foo, foo (>= 1.0.0), foo (>= 1.3.0)’, it would only return ‘foo (>= 1.3.0)’).

Value

An object of class "DependsList".
Description

Vignettes are normally processed by Sweave, but package writers may choose to use a different engine (e.g., one provided by the \texttt{knitr}, \texttt{noweb} or \texttt{R.rsp} packages). This function is used by those packages to register their engines, and internally by R to retrieve them.

Usage

\begin{verbatim}
vignetteEngine(name, weave, tangle, pattern = NULL, package = NULL, aspell = list())
\end{verbatim}

Arguments

- **name**: the name of the engine.
- **weave**: a function to convert vignette source files to LaTeX output.
- **tangle**: a function to convert vignette source files to R code.
- **pattern**: a regular expression pattern for the filenames handled by this engine, or NULL for the default pattern.
- **package**: the package registering the engine. By default, this is the package calling \texttt{vignetteEngine}.
- **aspell**: a list with element names \texttt{filter} and/or \texttt{control} giving the respective arguments to be used when spell checking the text in the vignette source file with \texttt{aspell}.

Details

If \texttt{weave} is missing, \texttt{vignetteEngine} will return the currently registered engine matching \texttt{name} and \texttt{package}.

If \texttt{weave} is NULL, the specified engine will be deleted.

Other settings define a new engine. The \texttt{weave} and \texttt{tangle} functions must be defined with argument lists compatible with \texttt{function(file, \ldots)}. Currently the \ldots arguments may include logical argument \texttt{quiet} and character argument \texttt{encoding}; others may be added in future. These are described in the documentation for \texttt{Sweave} and \texttt{Stangle}. 

Examples

\begin{verbatim}
# This may not be installed
gridEx <- system.file("doc", "grid.Rnw", package = "grid")
vignetteDepends(gridEx)
\end{verbatim}
The `weave` and `tangle` functions should return the filename of the output file that has been produced. Currently the `weave` function, when operating on a file named `<name> <pattern>` must produce a file named `<name>.[.](.tex|.pdf|.html)`. The `.tex` files will be processed by pdflatex to produce `.pdf` output for display to the user; the others will be displayed as produced. The `tangle` function must produce a file named `<name>[.]([r|R][s|S])` containing the executable R code from the vignette. The `tangle` function may support a `split = TRUE` argument, and then it should produce files named `<name>.*[.]([r|R][s|S])`.

The `pattern` argument gives a regular expression to match the extensions of files which are to be processed as vignette input files. If set to `NULL`, the default pattern `"[.]([Rr]Ss)(nw|tex)$"` is used.

### Value

If the engine is being deleted, `NULL`. Otherwise a list containing components

- `name` The name of the engine
- `package` The name of its package
- `pattern` The pattern for vignette input files
- `weave` The weave function
- `tangle` The tangle function

### Author(s)

Duncan Murdoch and Henrik Bengtsson.

### See Also

Sweave and the ‘Writing R Extensions’ manual.

### Examples

```r
str(vignetteEngine("Sweave"))
```

---

### Description

Generate ‘PACKAGES’ and ‘PACKAGES.gz’ files for a repository of source or Mac/Windows binary packages.

### Usage

```r
write_PACKAGES(dir = ".", fields = NULL, 
   type = c("source", "mac.binary", "win.binary"), 
   verbose = FALSE, unpacked = FALSE, subdirs = FALSE, 
   latestOnly = TRUE, addFiles = FALSE)
```
write_PACKAGES

Arguments

dir Character vector describing the location of the repository (directory including source or binary packages) to generate the ‘PACKAGES’ and ‘PACKAGES.gz’ files from and write them to.

fields a character vector giving the fields to be used in the ‘PACKAGES’ and ‘PACKAGES.gz’ files in addition to the default ones, or NULL (default). The default corresponds to the fields needed by available.packages: c("Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS_type", "License" and "Archs"), and those fields will always be included, plus the file name in field "File" if addFiles = TRUE and the path to the subdirectory in field "Path" if subdirectories are used.

type Type of packages: currently source ‘.tar.gz’ or ‘.tar.gz’ archives, and OS X or Windows binary (‘.tgz’ or ‘.zip’, respectively) packages are supported. Defaults to “win.binary” on Windows and to "source" otherwise.

verbose logical. Should packages be listed as they are processed?

unpacked a logical indicating whether the package contents are available in unpacked form or not (default).

subdirs either logical (to indicate if subdirectories should be included, recursively) or a character vector of name of subdirectories to include.

latestOnly logical: if multiple versions of a package are available should only the latest version be included?

addFiles logical: should the filenames be included as field ‘File’ in the ‘PACKAGES’ file.

Details

write_PACKAGES scans the named directory for R packages, extracts information from each package’s ‘DESCRIPTION’ file, and writes this information into the ‘PACKAGES’ and ‘PACKAGES.gz’ files. Including non-latest versions of packages is only useful if they have less constraining version requirements, so for example latestOnly = FALSE could be used for a source repository when ‘foo_1.0’ depends on ‘R >= 2.15.0’ but ‘foo_0.9’ is available which depends on ‘R >= 2.11.0’.

Support for repositories with subdirectories and hence for subdirs ! = FALSE depends on recording a "Path" field in the ‘PACKAGES’ file.

Support for more general file names (e.g., other types of compression) via a "File" field in the ‘PACKAGES’ file can be used by download.packages. If the file names are not of the standard form, use addFiles = TRUE.

type = "win.binary" uses unz connections to read all ‘DESCRIPTION’ files contained in the (zipped) binary packages for Windows in the given directory dir, and builds files ‘PACKAGES’ and ‘PACKAGES.gz’ files from this information.

Value

Invisibly returns the number of packages described in the resulting ‘PACKAGES’ and ‘PACKAGES.gz’ files. If 0, no packages were found and no files were written.

Note

Processing ‘.tar.gz’ archives to extract the ‘DESCRIPTION’ files is quite slow.

This function can be useful on other OSes to prepare a repository to be accessed by Windows machines, so type = "win.binary" should work on all OSes.
Author(s)

Uwe Ligges and R-core.

See Also

See read.dcf and write.dcf for reading 'DESCRIPTION' files and writing the 'PACKAGES' and 'PACKAGES.gz' files.

Examples

```r
## Not run:
write_PACKAGES("c:/myFolder/myRepository") # on Windows
write_PACKAGES("/pub/Rwin/bin/windows/contrib/2.9",
              type = "win.binary") # on Linux

## End(Not run)
```

---

**xgettext**

*Extract Translatable Messages from R Files in a Package*

**Description**

For each file in the ‘R’ directory (including system-specific subdirectories) of a package, extract the unique arguments passed to `stop`, `warning`, `message`, `gettext` and `gettextf`, or to `ngettext`.

**Usage**

```r
xgettext(dir, verbose = FALSE, asCall = TRUE)
	xngettext(dir, verbose = FALSE)

xgettext2pot(dir, potFile, name = "R", version, bugs)
```

**Arguments**

- `dir` the directory of a source package.
- `verbose` logical: should each file be listed as it is processed?
- `asCall` logical: if TRUE each argument is returned whole, otherwise the strings within each argument are extracted.
- `potFile` name of po template file to be produced. Defaults to ‘R-pkgname.pot’ where `pkgname` is the basename of ‘dir’.
- `name, version, bugs` as recorded in the template file: version defaults the version number of the currently running R, and bugs to "bugs.r-project.org".
Details

Leading and trailing white space (space, tab and linefeed) is removed for calls to gettext, gettextf, stop, warning, and message, as it is by the internal code that passes strings for translation.

We look to see if these functions were called with domain = NA and if so omit the call if asCall = TRUE: note that the call might contain a call to gettext which would be visible if asCall = FALSE.

xgettext2pot calls xgettext and then xngettext, and writes a PO template file for use with the GNU Gettext tools. This ensures that the strings for simple translation are unique in the file (as GNU Gettext requires), but does not do so for ngettext calls (and the rules are not stated in the Gettext manual, but msgfmt complains if there is duplication between the sets.).

If applied to the base package, this also looks in the ‘.R’ files in ‘R_HOME/share/R’.

Value

For xgettext, a list of objects of class "xgettext" (which has a print method), one per source file that potentially contains translatable strings.

For xngettext, a list of objects of class "xngettext", which are themselves lists of length-2 character strings.

See Also

update_pkg_po() which calls xgettext2pot().

Examples

```r
## Not run: ## in a source-directory build of R:
xgettext(file.path(R.home(), "src", "library", "splines"))

## End(Not run)
```

adist

Approximate String Distances

Description

Compute the approximate string distance between character vectors. The distance is a generalized
Levenshtein (edit) distance, giving the minimal possibly weighted number of insertions, deletions
and substitutions needed to transform one string into another.

Usage

adist(x, y = NULL, costs = NULL, counts = FALSE, fixed = TRUE,
partial = !fixed, ignore.case = FALSE, useBytes = FALSE)
Arguments

- **x**: a character vector. **Long vectors** are not supported.
- **y**: a character vector, or NULL (default) indicating taking x as y.
- **costs**: a numeric vector or list with names partially matching ‘insertions’, ‘deletions’ and ‘substitutions’ giving the respective costs for computing the Levenshtein distance, or NULL (default) indicating using unit cost for all three possible transformations.
- **counts**: a logical indicating whether to optionally return the transformation counts (numbers of insertions, deletions and substitutions) as the “counts” attribute of the return value.
- **fixed**: a logical. If TRUE (default), the x elements are used as string literals. Otherwise, they are taken as regular expressions and partial = TRUE is implied (corresponding to the approximate string distance used by `agrep` with fixed = FALSE).
- **partial**: a logical indicating whether the transformed x elements must exactly match the complete y elements, or only substrings of these. The latter corresponds to the approximate string distance used by `agrep` (by default).
- **ignore.case**: a logical. If TRUE, case is ignored for computing the distances.
- **useBytes**: a logical. If TRUE distance computations are done byte-by-byte rather than character-by-character.

Details

The (generalized) Levenshtein (or edit) distance between two strings s and t is the minimal possibly weighted number of insertions, deletions and substitutions needed to transform s into t (so that the transformation exactly matches t). This distance is computed for partial = FALSE, currently using a dynamic programming algorithm (see, e.g., [http://en.wikipedia.org/wiki/Levenshtein_distance](http://en.wikipedia.org/wiki/Levenshtein_distance)) with space and time complexity $O(mn)$, where $m$ and $n$ are the lengths of $s$ and $t$, respectively. Additionally computing the transformation sequence and counts is $O(\max(m, n))$.

The generalized Levenshtein distance can also be used for approximate (fuzzy) string matching, in which case one finds the substring of $t$ with minimal distance to the pattern $s$ (which could be taken as a regular expression, in which case the principle of using the leftmost and longest match applies), see, e.g., [http://en.wikipedia.org/wiki/Approximate_string_matching](http://en.wikipedia.org/wiki/Approximate_string_matching). This distance is computed for partial = TRUE using ‘tre’ by Ville Laurikari ([http://laurikari.net/tre/](http://laurikari.net/tre/)) and corresponds to the distance used by `agrep`. In this case, the given cost values are coerced to integer.

Note that the costs for insertions and deletions can be different, in which case the distance between $s$ and $t$ can be different from the distance between $t$ and $s$.

Value

A matrix with the approximate string distances of the elements of x and y, with rows and columns corresponding to x and y, respectively.

If counts is TRUE, the transformation counts are returned as the "counts" attribute of this matrix, as a 3-dimensional array with dimensions corresponding to the elements of x, the elements of y, and the type of transformation (insertions, deletions and substitutions), respectively. Additionally, if partial = FALSE, the transformation sequences are returned as the "trafos" attribute of the return value, as character strings with elements ‘M’, ‘I’, ‘D’ and ‘S’ indicating a match, insertion, deletion and substitution, respectively. If partial = TRUE, the offsets (positions of the first and last element) of the matched substrings are returned as the "offsets" attribute of the return value (with both offsets −1 in case of no match).
See Also

`agrep` for approximate string matching (fuzzy matching) using the generalized Levenshtein distance.

Examples

```r
adist("kitten", "sitting")
## To see the transformation counts for the Levenshtein distance:
drop(attr(adist("kitten", "sitting", counts = TRUE), "counts"))
## To see the transformation sequences:
attr(adist(c("kitten", "sitting"), counts = TRUE), "trafos")

## Cf. the examples for agrep:
adist("lazy", "1 lazy 2")
## For a "partial approximate match" (as used for agrep):
adist("lazy", "1 lazy 2", partial = TRUE)
```

```
alarm

_Alert the User_

Description

Gives an audible or visual signal to the user.

Usage

`alarm()`

Details

`alarm()` works by sending a "\a" character to the console. On most platforms this will ring a bell, beep, or give some other signal to the user (unless standard output has been redirected).

It attempts to flush the console (see `flush.console`).

Value

No useful value is returned.

Examples

`alarm()`
**Description**

`apropos()` returns a character vector giving the names of all objects in the search list matching `what`. 
`find()` is a different user interface to the same task.

**Usage**

```r
apropos(what, where = FALSE, ignore.case = TRUE, mode = "any")
```

```r
find(what, mode = "any", numeric = FALSE, simple.words = TRUE)
```

**Arguments**

- **what** character string with name of an object, or more generally a regular expression to match against.
- **where**, **numeric** a logical indicating whether positions in the search list should also be returned.
- **ignore.case** logical indicating if the search should be case-insensitive, `TRUE` by default. Note that in R versions prior to 2.5.0, the default was implicitly `ignore.case = FALSE`.
- **mode** character; if not "any", only objects whose mode equals mode are searched.
- **simple.words** logical; if TRUE, the what argument is only searched as whole word.

**Details**

If `mode != "any"` only those objects which are of mode `mode` are considered. If `where` is `TRUE`, the positions in the search list are returned as the names attribute. 
`find` is a different user interface for the same task as `apropos`. However, by default (simple.words == TRUE), only full words are searched with `grep(fixed = TRUE)`.

**Value**

For `apropos` character vector, sorted by name, possibly with names giving the (numerical) positions on the search path.
For `find`, either a character vector of environment names, or for numeric = `TRUE`, a numerical vector of positions on the search path, with names giving the names of the corresponding environments.

**Author(s)**

Kurt Hornik and Martin Maechler (May 1997).

**See Also**

- [glob2rx](#) to convert wildcard patterns to regular expressions.
- [objects](#) for listing objects from one place, [help.search](#) for searching the help system, [search](#) for the search path.
Examples

require(stats)

## Not run: apropos("lm")
apropos("GLM")  # more than a dozen
## that may include internal objects starting '._C_' if
## methods is attached
apropos("GLM", ignore.case = FALSE) # not one
apropos("lq")

cor <- 1:pi
find("cor")  # ".GlobalEnv"  "package:stats"
find("cor", numeric = TRUE)  # numbers with these names
find("cor", numeric = TRUE, mode = "function")  # only the second one
rm(cor)

## Not run: apropos(".", mode="list")  # a long list

# need a DOUBLE backslash \\ (in case you don't see it anymore)
apropos("\\[")

# everything % not diff-able
length(apropos("."))

# those starting with 'pr'
apropos("pr")

# the 1-letter things
apropos(".^")
# the 1-2-letter things
apropos("^..?")
# the 2-to-4 letter things
apropos("^..(2,4)$")

# the 8-and-more letter things
apropos("^..(8)$")
table(nchar(apropos("^..(8)$")))

aregexec  Approximate String Match Positions

Description

Determine positions of approximate string matches.

Usage

aregexec(pattern, text, max.distance = 0.1, costs = NULL,
ignore.case = FALSE, fixed = FALSE, useBytes = FALSE)
Arguments

- **pattern**: a non-empty character string or a character string containing a regular expression (for `fixed = FALSE`) to be matched. Coerced by `as.character` to a string if possible.
- **text**: character vector where matches are sought. Coerced by `as.character` to a character vector if possible.
- **max.distance**: maximum distance allowed for a match. See `agrep`.
- **costs**: cost of transformations. See `agrep`.
- **ignore.case**: a logical. If TRUE, case is ignored for computing the distances.
- **fixed**: If TRUE, the pattern is matched literally (as is). Otherwise (default), it is matched as a regular expression.
- **useBytes**: a logical. If TRUE comparisons are byte-by-byte rather than character-by-character.

Details

`aregexec` provides a different interface to approximate string matching than `agrep` (along the lines of the interfaces to exact string matching provided by `regexec` and `grep`).

Note that by default, `agrep` performs literal matches, whereas `aregexec` performs regular expression matches.

See `agrep` and `adist` for more information about approximate string matching and distances.

Comparisons are byte-by-byte if `pattern` or any element of `text` is marked as "bytes".

Value

A list of the same length as `text`, each element of which is either −1 if there is no match, or a sequence of integers with the starting positions of the match and all substrings corresponding to parenthesized subexpressions of `pattern`, with attribute "match.length" an integer vector giving the lengths of the matches (or −1 for no match).

See Also

- `regmatches` for extracting the matched substrings.

Examples

```r
# Cf. the examples for agrep.
x <- c("1 lazy", "1", "1 LAZY")
ageexec("laysy", x, max.distance = 2)
ageexec("(lay)(sy)", x, max.distance = 2)
ageexec("(lay)(sy)", x, max.distance = 2, ignore.case = TRUE)
m <- ageexec("(lay)(sy)", x, max.distance = 2)
regmatches(x, m)
```
aspell

Spell Check Interface

Description

Spell check given files via Aspell, Hunspell or Ispell.

Usage

    aspell(files, filter = NULL, control = list(), encoding = "unknown",
            program = NULL, dictionaries = character())

Arguments

files a character vector with the names of files to be checked.

filter an optional filter for processing the files before spell checking, given as either a
        function (with formals ifile and encoding), or a character string specifying a
        built-in filter, or a list with the name of a built-in filter and additional arguments
        to be passed to it. See Details for available filters. If missing or NULL, no filtering
        is performed.

control a list or character vector of control options for the spell checker.

encoding the encoding of the files. Recycled as needed.

program a character string giving the name (if on the system path) or full path of the
        spell check program to be used, or NULL (default). By default, the system path
        is searched for aspell, hunspell and ispell (in that order), and the first one
        found is used.

dictionaries a character vector of names or file paths of additional R level dictionaries to use.
        Elements with no path separator specify R system dictionaries (in subdirectory
        ‘share/dictionaries’ of the R home directory). The file extension (currently,
        only ‘.rds’) can be omitted.

Details

The spell check programs employed must support the so-called Ispell pipe interface activated via
command line option ‘-a’. In addition to the programs, suitable dictionaries need to be available. See http://aspell.net, http://hunspell.sourceforge.net/ and http://lasr.cs.ucla.edu/geoff/ispell.html, respectively, for obtaining the Aspell, Hunspell and (International) Ispell programs and dictionaries.

The currently available built-in filters are "Rd" (corresponding to RdTextFilter), "Sweave" (corresponding to SweaveTeXFilter), "R", "pot" and "dcf".

Filter "R" is for R code and extracts the message string constants in calls to message, warning, stop, packageStartupMessage, gettext, gettextf, and ngettext (the unnamed string constants for the first five, and fmt and msg1/msg2 string constants, respectively, for the latter two). Filter "pot" is for message string catalog ‘.pot’ files. Both have an argument ignore allowing to give regular expressions for parts of message strings to be ignored for spell checking: e.g., using "^[ \t]\^[^]*[^\t[[:punct:]]]" ignores all text inside single quotes.

Filter "dcf" is for files in Debian Control File format. The fields to keep can be controlled by argument keep (a character vector with the respective field names). By default, ‘Title’ and ‘Description’ fields are kept.
The print method has for the objects returned by aspell has an indent argument controlling the indentation of the positions of possibly mis-spelled words. The default is 2; Emacs users may find it useful to use an indentation of 0 and visit output in grep-mode. It also has a verbose argument: when this is true, suggestions for replacements are shown as well.

It is possible to employ additional R level dictionaries. Currently, these are files with extension `.rds` obtained by serializing character vectors of word lists using `saveRDS`. If such dictionaries are employed, they are combined into a single word list file which is then used as the spell checker’s personal dictionary (option ‘-p’): hence, the default personal dictionary is not used in this case.

**Value**

A data frame inheriting from aspell (which has a useful print method) with the information about possibly mis-spelled words.

**References**

**See Also**

aspell-utils for utilities for spell checking packages.

Package Aspell on Omegahat ([http://www.omegahat.org/Aspell](http://www.omegahat.org/Aspell)) for a fine-grained R interface to the Aspell library.

**Examples**

```r
## Not run:
## To check all Rd files in a directory, (additionally) skipping the
## \references sections.
files <- Sys.glob("*.Rd")
aspell(files, filter = list("Rd", drop = "\references"))

## To check all Sweave files
files <- Sys.glob(c("*.Rnw", "*.Snw", "*.rnw", "*.snw"))
aspell(files, filter = "Sweave", control = "-t")

## To check all Texinfo files (Aspell only)
files <- Sys.glob("*.texi")
aspell(files, control = "--mode= texinfo")

## End(Not run)

## List the available R system dictionaries.
Sys.glob(file.path(R.home("share"), "dictionaries", "*.rds"))
```

---

**aspell-utils**

**Spell Check Utilities**

**Description**

Utilities for spell checking packages via Aspell, Hunspell or Ispell.
Usage

```r
aspell_package_Rd_files(dir, drop = c("\author", "\references"),
control = list(), program = NULL,
dictionaries = character())
```

```r
aspell_package_vignettes(dir,
control = list(), program = NULL,
dictionaries = character())
```

```r
aspell_package_R_files(dir, ignore = character(), control = list(),
program = NULL, dictionaries = character())
```

```r
aspell_package_C_files(dir, ignore = character(), control = list(),
program = NULL, dictionaries = character())
```

```r
aspell_write_personal_dictionary_file(x, out, language = "en",
program = NULL)
```

Arguments

- **dir**: a character string specifying the path to a package’s root directory.
- **drop**: a character vector naming additional Rd sections to drop when selecting text via `RdTextFilter`.
- **control**: a list or character vector of control options for the spell checker.
- **program**: a character string giving the name (if on the system path) or full path of the spell check program to be used, or NULL (default). By default, the system path is searched for `aspell`, `hunspell` and `ispell` (in that order), and the first one found is used.
- **dictionaries**: a character vector of names or file paths of additional R level dictionaries to use. See `aspell`.
- **ignore**: a character vector with regular expressions to be replaced by blanks when filtering the message strings.
- **x**: a character vector, or the result of a call to `aspell()`.
- **out**: a character string naming the personal dictionary file to write to.
- **language**: a character string indicating a language as used by Aspell.

Details

Functions `aspell_package_Rd_files`, `aspell_package_vignettes`, `aspell_package_R_files` and `aspell_package_C_files` perform spell checking on the Rd files, vignettes, R files, and C-level messages of the package with root directory `dir`. They determine the respective files, apply the appropriate filters, and run the spell checker. See `aspell` for details on filters.

The C-level message string are obtained from the ‘po/PACKAGE.pot’ message catalog file, with `PACKAGE` the basename of `dir`. See the section on “C-level messages” in “Writing R Extensions” for more information.

When using Aspell, the vignette checking skips parameters and/or options of commands `\Sexpr`, `\citep`, `\code`, `\pkg`, `\proglang` and `\samp`. Further commands can be skipped by adding --add-tex-command options to the `control` argument. E.g., to skip both option and parameter of `\mycmd`, add --add-tex-command=’\mycmd op’.

Suitable values for `control`, `program`, `dictionaries`, `drop` and `ignore` can also be specified using a package defaults file which should go as ‘`defaults.R`’ into the `.aspell` subdirectory of `dir`, and provides defaults via assignments of suitable named lists, e.g.,
vignettes <- list(control = "--add-tex-command='mycmd op'")

for vignettes (when using Aspell) and similarly assigning to Rd_files, R_files and C_files for Rd files, R files and C level message defaults.

Maintainers of packages using both English and American spelling will find it convenient to pass control options "--master=en_US" and "--add-extra-dicts=en_GB" to Aspell and control options "-d en_US,en_GB" to Hunspell (provided that the corresponding dictionaries are installed).

Older versions of R had no support for R level dictionaries, and hence provided the function aspell_write_personal_dictionary_file to create (spell check) program-specific personal dictionary files from words to be accepted. The new mechanism is to use R level dictionaries, i.e., `.rds` files obtained by serializing character vectors of such words using `saveRDS`. For such dictionaries specified via the package defaults mechanism, elements with no path separator can be R system dictionaries or dictionaries in the `.` subdirectory.

`aspell`

available.packages

List Available Packages at CRAN-like Repositories

Description

`available.packages` returns a matrix of details corresponding to packages currently available at one or more repositories. The current list of packages is downloaded over the internet (or copied from a local mirror).

Usage

```r
available.packages(contriburl =
    contrib.url(getOption("repos"), type),
    method, fields = NULL,
    type = getOption("pkgType"),
    filters = NULL)
```

Arguments

- `contriburl` URL(s) of the `contrib` sections of the repositories. Specify this argument only if your repository mirror is incomplete, e.g., because you burned only the `contrib` section on a CD.
- `method` download method, see `download.file`.
- `type` character string, indicate which type of packages: see `install.packages`. If type = "both" this will use the source repository.
- `fields` a character vector giving the fields to extract from the `PACKAGES` file(s) in addition to the default ones, or NULL (default). Unavailable fields result in NA values.
- `filters` a character vector or list or NULL (default). See ‘Details’.
The list of packages is either copied from a local mirror (specified by a ‘file://’ URI) or downloaded. If downloaded, the list is cached for the R session in a per-repository file in `tempdir()` with a name like

`repos_http%3a%2f%2fcran.r-project.org%2fsrc%2fcontrib.rds`

By default, the return value includes only packages whose version and OS requirements are met by the running version of R, and only gives information on the latest versions of packages.

Argument filters can be used to select which of the packages on the repositories are reported. It is called with its default value (NULL) by functions such as `install.packages`; this value corresponds to `getOption("available_packages_filters")` and to `c("R_version", "OS_type", "subarch", "duplicates")` if that is unset or set to NULL.

The built-in filters are

- "R_version" Exclude packages whose R version requirements are not met.
- "OS_type" Exclude packages whose OS requirement is incompatible with this version of R; that is exclude Windows-only packages on a Unix-alike platform and *vice versa*.
- "subarch" For binary packages, exclude those with compiled code that is not available for the current sub-architecture, e.g. exclude packages only compiled for 32-bit Windows on a 64-bit Windows R.
- "duplicates" Only report the latest version where more than one version is available, and only report the first-named repository (in `contriburl`) with the latest version if that is in more than one repository.
- "license/FOSS" Include only packages for which installation can proceed solely based on packages which can be verified as Free or Open Source Software (FOSS, e.g., [http://en.wikipedia.org/wiki/FOSS](http://en.wikipedia.org/wiki/FOSS)) employing the available license specifications. Thus both the package and any packages that it depends on to load need to be known to be FOSS.

Note that this does depend on the repository supplying license information.

- "license/restricts_use" Include only packages for which installation can proceed solely based on packages which are known not to restrict use.
- "CRAN" Use CRAN versions in preference to versions from other repositories (even if these have a higher version number). This needs to be applied before the default "duplicates" filter, so cannot be used with add = TRUE.

If all the filters are from this set, then they can be specified as a character vector; otherwise filters should be a list with elements which are character strings, user-defined functions or add = TRUE (see below).

User-defined filters are functions which take a single argument, a matrix of the form returned by `available.packages`, and return a matrix consisting of a subset of the rows of the argument.

The special ‘filter’ add = TRUE appends the other elements of the filter list to the default filters.

**Value**

A matrix with one row per package, row names the package names and column names including "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "File" and "Repository". Additional columns can be specified using the fields argument.

Where provided by the repository, fields "OS_type", "License", "License_is_FOSS", "License_restricts_use", "Arches", "MD5sum" and "NeedsCompilation" are reported for use by the filters and package management tools, including `install.packages`. 
The 'R Installation and Administration' manual for how to set up a repository.

**Examples**

```r
## Not run:
## Restrict install.packages() (etc) to known-to-be-FLOSS packages
options(available_packages_filters =
c("R_version", "OS_type", "subarch", "duplicates", "license/FLOSS"))
## or
options(available_packages_filters = list(add = TRUE, "license/FLOSS"))

## Give priority to released versions on CRAN, rather than development
## versions on Omegahat, R-Forge etc.
options(available_packages_filters =
c("R_version", "OS_type", "subarch", "CRAN", "duplicates"))

## End(Not run)
```

**Description**

Run R non-interactively with input from `infile` and send output (stdout/stderr) to another file.

**Usage**

```r
R CMD BATCH [options] infile [outfile]
```

**Arguments**

`infile` the name of a file with R code to be executed.

`options` a list of R command line options, e.g., for setting the amount of memory available and controlling the load/save process. If `infile` starts with a `-`, use `--` as the final option. The default options are `--restore --save --no-readline`. (Without `--no-readline` on Windows.)

`outfile` the name of a file to which to write output. If not given, the name used is that of `infile`, with a possible `.R` extension stripped, and `.Rout` appended.

**Details**

Use `R CMD BATCH --help` to be reminded of the usage.

By default, the input commands are printed along with the output. To suppress this behavior, add `options(echo = FALSE)` at the beginning of `infile`, or use option `--slave`.

The `infile` can have end of line marked by LF or CRLF (but not just CR), and files with an incomplete last line (missing end of line (EOL) mark) are processed correctly.

A final expression `proc.time()` will be executed after the input script unless the latter calls `q(runLast = FALSE)` or is aborted. This can be suppressed by the option `--no-timing`. 
Additional options can be set by the environment variable `R_BATCH_OPTIONS`; these come after the default options (see the description of the `options` argument) and before any options given on the command line.

**Note**

Unlike Splus BATCH on a Unix-alike, this does not run the R process in the background. In most shells,

```
R CMD BATCH [options] infile [outfile] &
```

will do so.

### bibentry

#### Bibliography Entries

**Description**

Functionality for representing and manipulating bibliographic information in enhanced BibTeX style.

**Usage**

```r
bibentry(bibtype, textVersion = NULL, header = NULL, footer = NULL,
    key = NULL, ..., other = list(),
    mheader = NULL, mfooter = NULL)
```

```r
## S3 method for class 'bibentry'
print(x, style = "text", .bibstyle, ...)
```

**Arguments**

- `bibtype` a character string with a BibTeX entry type. See **Entry Types** for details.
- `textVersion` a character string with a text representation of the reference to optionally be employed for printing.
- `header` a character string with optional header text.
- `footer` a character string with optional footer text.
- `key` a character string giving the citation key for the entry.
- `...` for `bibentry`: arguments of the form `tag=value` giving the fields of the entry, with `tag` and `value` the name and value of the field, respectively. Arguments with empty values are dropped. See **Entry Fields** for details.
  - For the `print` method, extra parameters to pass to the renderer.
- `other` a list of arguments as in `...` (useful in particular for fields named the same as formals of `bibentry`).
- `mheader` a character string with optional “outer” header text.
- `mfooter` a character string with optional “outer” footer text.
- `x` an object inheriting from class “bibentry”.
- `style` an optional character string specifying the print style. If present, must be a unique abbreviation (with case ignored) of the available styles, see **Details**.
- `.bibstyle` a character string naming a bibliography style.
Details

The bibentry objects created by bibentry can represent an arbitrary positive number of references. One can use c() to combine bibentry objects, and hence in particular build a multiple reference object from single reference ones. Alternatively, one can use bibentry to directly create a multiple reference object by “vectorizing” the given arguments, i.e., use character vectors instead of character strings.

The print method for bibentry objects provides a choice between seven different styles: plain text (style "text"), BibTeX ("Bibtex"), a mixture of plain text and BibTeX as traditionally used for citations ("citation"), HTML ("html"), LaTeX ("latex"), R code ("R"), and a simple copy of the textVersion elements (style "textVersion"). The "text", "html" and "latex" styles make use of the .bistyle argument using the bibstyle function. When printing bibentry objects in citation style, a header/footer for each item can be displayed as well as a mheader/mfooter for the whole vector of references.

The print method is based on a format method which provides the same styles, and for formatting as R code a choice between giving a character vector with one bibentry() call for each bibentry (as commonly used in ' CITATION ' files), or a character string with one collapsed call, obtained by combining the individual calls with c() if there is more than one bibentry. This can be controlled by setting the option collapse to FALSE (default) or TRUE, respectively. (Printing in R style always collapses to a single call.) Further, for the "citation" style, format()’s optional argument citation.bibtex.max (with default getCitationOption("citation.bibtex.max") which defaults to 1) determines for up to how many citation bibentries text style is shown together with with bibtex, automatically.

It is possible to subscript bibentry objects by their keys (which are used for character subscripts if the names are NULL).

There is also a toBibtex method for direct conversion to BibTeX.

Value

bibentry produces an object of class "bibentry".

Entry Types

bibentry creates "bibentry" objects, which are modeled after BibTeX entries. The entry should be a valid BibTeX entry type, e.g.,

Article: An article from a journal or magazine.
InBook: A part of a book, which may be a chapter (or section or whatever) and/or a range of pages.
InCollection: A part of a book having its own title.
InProceedings: An article in a conference proceedings.
Misc: Use this type when nothing else fits.
Proceedings: The proceedings of a conference.
TechReport: A report published by a school or other institution, usually numbered within a series.
Unpublished: A document having an author and title, but not formally published.
Entry Fields

The ... argument of \texttt{bibentry} can be any number of \LaTeX\ fields, including

\begin{itemize}
  \item \texttt{address}: The address of the publisher or other type of institution.
  \item \texttt{author}: The name(s) of the author(s), either as a character string in the format described in the \LaTeX\ book, or a \texttt{person} object.
  \item \texttt{booktitle}: Title of a book, part of which is being cited.
  \item \texttt{chapter}: A chapter (or section or whatever) number.
  \item \texttt{editor}: Name(s) of editor(s), same format as author.
  \item \texttt{institution}: The publishing institution of a technical report.
  \item \texttt{journal}: A journal name.
  \item \texttt{note}: Any additional information that can help the reader. The first word should be capitalized.
  \item \texttt{number}: The number of a journal, magazine, technical report, or of a work in a series.
  \item \texttt{pages}: One or more page numbers or range of numbers.
  \item \texttt{publisher}: The publisher’s name.
  \item \texttt{school}: The name of the school where a thesis was written.
  \item \texttt{series}: The name of a series or set of books.
  \item \texttt{title}: The work’s title.
  \item \texttt{volume}: The volume of a journal or multi-volume book.
  \item \texttt{year}: The year of publication.
\end{itemize}

\texttt{person}

Examples

```r
## R reference
rref <- \texttt{bibentry(}
  \texttt{  bibtype = "Manual",
  title = "R: A Language and Environment for Statistical Computing",
  author = \texttt{person("R Core Team")},
  organization = "R Foundation for Statistical Computing",
  address = "Vienna, Austria",
  year = 2014,
  url = "http://www.R-project.org/"
)

## Different printing styles
print(rref)
p\texttt{rint(rref, style = "Bibtex")
print(rref, style = "citation")
print(rref, style = "html")
print(rref, style = "latex")
print(rref, style = "R")

## References for boot package and associated book
bref <- \texttt{c(}
  \texttt{  bibentry(}
    \texttt{    bibtype = "Manual",
    title = "boot: Bootstrap R (S-PLUS) Functions",
  }
)```
browseEnv

Browse Objects in Environment

Description

The browseEnv function opens a browser with list of objects currently in \texttt{sys.frame}() environment.

```r
author = c(
  person("Angelo", "Canty", role = "aut",
    comment = "S original"),
  person(c("Brian", "D."), "Ripley", role = c("aut", "tr1", "cre"),
    comment = "R port, author of parallel support",
    email = "ripley@stats.ox.ac.uk")
),
year = "2012",
note = "R package version 1.3-4",
url = "http://CRAN.R-project.org/package=boot",
key = "boot-package"
),
bibentry(
  bibtype = "Book",
  title = "Bootstrap Methods and Their Applications",
  author = as.person("Anthony C. Davison [aut], David V. Hinkley [aut]")
),
year = "1997",
publisher = "Cambridge University Press",
address = "Cambridge",
isbn = "0-521-57391-2",
url = "http://statwww.epfl.ch/davison/BMA/",
key = "boot-book"
)

## Combining and subsetting
c(ref, brief)
bref[2]
bref["boot-book"]

## Extracting fields
bref$author
bref[[1]]$author
bref[[1]]$author[[2]]$email

## Convert to BibTeX
toBibtex(bref)

## Format in R style
## One \texttt{bibentry} call for each \texttt{bibentry}:
writeLines(paste(format(bref, "R"), collapse = "\n\n"))
## One collapsed call:
writeLines(format(bref, "R", collapse = TRUE))
```
**Usage**

```r
displayEnv = .GlobalEnv, pattern,
excludepatt = "last\|\.warning",
html = .Platform$GUI ! = "AQUA",
excludepatt = TRUE, properties = NULL,
main = NULL, debugMe = FALSE)
```

**Arguments**

- `envir`: an environment the objects of which are to be browsed.
- `pattern`: a regular expression for object subselection is passed to the internal `ls()` call.
- `excludepatt`: a regular expression for dropping objects with matching names.
- `html`: is used to display the workspace on a HTML page in your favorite browser. The default except when running from `R.app` on OS X.
- `expanded`: whether to show one level of recursion. It can be useful to switch it to FALSE if your workspace is large. This option is ignored if `html` is set to FALSE.
- `properties`: a named list of global properties (of the objects chosen) to be showed in the browser; when NULL (as per default), user, date, and machine information is used.
- `main`: a title string to be used in the browser; when NULL (as per default) a title is constructed.
- `debugMe`: logical switch; if true, some diagnostic output is produced.

**Details**

Very experimental code: displays a static HTML page on all platforms except R.app on OS X.

Only allows one level of recursion into object structures.

It can be generalized. See sources for details. Most probably, this should rather work through using the ‘tkWidget’ package (from [http://www.bioconductor.org](http://www.bioconductor.org)).

**See Also**

- `str`, `ls`.

**Examples**

```r
if(interactive()) {
  ## create some interesting objects:
  ofa <- ordered(4:1)
  ex1 <- expression(1+ 0:9)
  ex3 <- expression(u, v, 1+ 0:9)
  example(factor, echo = FALSE)
  example(table, echo = FALSE)
  example(ufactor, echo = FALSE)
  example(1m, echo = FALSE, ask = FALSE)
  example(str, echo = FALSE)

  ## and browse them:
  displayEnv()

  ## a (simple) function's environment:
```
browseURL <- approxfun(1:2, 1:2, method = "const")
browseEnv(envir = environment(afl2))
}

browseURL

Description
Load a given URL into a WWW browser.

Usage
browseURL(url, browser =getOption("browser"),
encodeIfNeeded = FALSE)

Arguments
url a non-empty character string giving the URL to be loaded.
browser a non-empty character string giving the name of the program to be used as hypertext browser. It should be in the PATH, or a full path specified. Alternatively, an R function to be called to invoke the browser.
Under Windows NULL is also allowed (and is the default), and implies that the file association mechanism will be used.
encodeIfNeeded Should the URL be encoded by URLencode before passing to the browser? This is not needed (and might be harmful) if the browser program/function itself does encoding, and can be harmful for 'file://' URLs on some systems and for 'http://' URLs passed to some CGI applications. Fortunately, most URLs do not need encoding.

Details
The default browser is set by option "browser", in turn set by the environment variable \R_BROWSER which is by default set in file \R_HOME/etc/Renviron\ to a choice made manually or automatically when R was configured. (See Startup for where to override that default value.) To suppress showing URLs altogether, use the value "false".

If browser supports remote control and R knows how to perform it, the URL is opened in any already running browser or a new one if necessary. This mechanism currently is available for browsers which support the "-remote openURL(...)" interface (which includes Mozilla >= 0.9.5 and Mozilla Firefox), Galeon, KDE konqueror (via kfmclient) and the GNOME interface to Mozilla. Note that the type of browser is determined from its name, so this mechanism will only be used if the browser is installed under its canonical name.

Because "-remote" will use any browser displaying on the X server (whatever machine it is running on), the remote control mechanism is only used if DISPLAY points to the local host. This may not allow displaying more than one URL at a time from a remote host.

It is the caller’s responsibility to encode url if necessary (see URLencode). This can be tricky for file URLs, where the format accepted can depend on both browser and OS.

To suppress showing URLs altogether, set browser = "false".

The behaviour for arguments url which are not URLs is platform-dependent. Some platforms accept absolute file paths; fewer accept relative file paths.
**browseVignettes**

## Examples

```r
## Not run: ## for KDE users who want to open files in a new tab
options(browser = "kfmcclient newTab")
browseURL("http://www.r-project.org")

## End(Not run)
```

**List Vignettes in an HTML Browser**

### Description

List available vignettes in an HTML browser with links to PDF, LaTeX/noweb source, and (tangled) R code (if available).

### Usage

```r
browseVignettes(package = NULL, lib.loc = NULL, all = TRUE)
```

### Arguments

- `package` a character vector with the names of packages to search through, or `NULL` in which "all" packages (as defined by argument `all`) are searched.
- `lib.loc` a character vector of directory names of R libraries, or `NULL`. The default value of `NULL` corresponds to all libraries currently known.
- `all` logical; if `TRUE` search all available packages in the library trees specified by `lib.loc`, and if `FALSE`, search only attached packages.
- `x` Object of class `browseVignettes`.
- `...` Further arguments, ignored by the `print` method.

### Details

Function `browseVignettes` returns an object of the same class; the print method displays it as an HTML page in a browser (using `browseURL`).

### See Also

`browseURL`, `vignette`

### Examples

```r
## List vignettes from all *attached* packages
browseVignettes(all = FALSE)

## List vignettes from a specific package
browseVignettes("grid")
```
Description

Invokes an editor or email program to write a bug report or opens a web page for bug submission. Some standard information on the current version and configuration of R are included automatically.

Usage

```r
bug.report(subject = "", address,
            file = "R.bug.report", package = NULL, lib.loc = NULL,
            ...)```

Arguments

- `subject` Subject of the email.
- `address` Recipient’s email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed).
- `file` filename to use (if needed) for setting up the email.
- `package` Optional character vector naming a single package which is the subject of the bug report.
- `lib.loc` A character vector describing the location of R library trees in which to search for the package, or NULL. The default value of NULL corresponds to all libraries currently known.
- `...` additional named arguments such as `method` and `ccaddress` to pass to `create.post`.

Details

If package is NULL or a base package, this opens the R bugs tracker at [http://bugs.r-project.org/](http://bugs.r-project.org/).

If package is specified, it is assumed that the bug report is about that package, and parts of its ’DESCRIPTION’ file are added to the standard information. If the package has a `BugReports` field in the ’DESCRIPTION’ file, that URL will be opened using `browseURL`, otherwise an email directed to the package maintainer will be generated using `create.post`.

Value

Nothing useful.

When is there a bug?

If R executes an illegal instruction, or dies with an operating system error message that indicates a problem in the program (as opposed to something like “disk full”), then it is certainly a bug.

Taking forever to complete a command can be a bug, but you must make certain that it was really R’s fault. Some commands simply take a long time. If the input was such that you KNOW it should have been processed quickly, report a bug. If you don’t know whether the command should take a long time, find out by looking in the manual or by asking for assistance.
If a command you are familiar with causes an R error message in a case where its usual definition ought to be reasonable, it is probably a bug. If a command does the wrong thing, that is a bug. But be sure you know for certain what it ought to have done. If you aren’t familiar with the command, or don’t know for certain how the command is supposed to work, then it might actually be working right. Rather than jumping to conclusions, show the problem to someone who knows for certain.

Finally, a command’s intended definition may not be best for statistical analysis. This is a very important sort of problem, but it is also a matter of judgement. Also, it is easy to come to such a conclusion out of ignorance of some of the existing features. It is probably best not to complain about such a problem until you have checked the documentation in the usual ways, feel confident that you understand it, and know for certain that what you want is not available. The mailing list r-devel@r-project.org is a better place for discussions of this sort than the bug list.

If you are not sure what the command is supposed to do after a careful reading of the manual this indicates a bug in the manual. The manual’s job is to make everything clear. It is just as important to report documentation bugs as program bugs.

If the online argument list of a function disagrees with the manual, one of them must be wrong, so report the bug.

How to report a bug

When you decide that there is a bug, it is important to report it and to report it in a way which is useful. What is most useful is an exact description of what commands you type, from when you start R until the problem happens. Always include the version of R, machine, and operating system that you are using; type version in R to print this. To help us keep track of which bugs have been fixed and which are still open please send a separate report for each bug.

The most important principle in reporting a bug is to report FACTS, not hypotheses or categorizations. It is always easier to report the facts, but people seem to prefer to strain to posit explanations and report them instead. If the explanations are based on guesses about how R is implemented, they will be useless; we will have to try to figure out what the facts must have been to lead to such speculations. Sometimes this is impossible. But in any case, it is unnecessary work for us.

For example, suppose that on a data set which you know to be quite large the command data.frame(x, y, z, monday, tuesday) never returns. Do not report that data.frame() fails for large data sets. Perhaps it fails when a variable name is a day of the week. If this is so then when we got your report we would try out the data.frame() command on a large data set, probably with no day of the week variable name, and not see any problem. There is no way in the world that we could guess that we should try a day of the week variable name.

Or perhaps the command fails because the last command you used was a method that had a bug causing R’s internal data structures to be corrupted and making the data.frame() command fail from then on. This is why we need to know what other commands you have typed (or read from your startup file).

It is very useful to try and find simple examples that produce apparently the same bug, and somewhat useful to find simple examples that might be expected to produce the bug but actually do not. If you want to debug the problem and find exactly what caused it, that is wonderful. You should still report the facts as well as any explanations or solutions.

Invoking R with the ‘--vanilla’ option may help in isolating a bug. This ensures that the site profile and saved data files are not read.

A bug report can be generated using the function bug.report(). For reports on R this will open the Web page at http://bugs.r-project.org/: for a contributed package it will open the package’s bug tracker Web page or help you compose an email to the maintainer.

Bug reports on contributed packages should not be sent to the R bug tracker: rather make use of the package argument.

capture.output  
Send Output to a Character String or File

Description

Evaluates its arguments with the output being returned as a character string or sent to a file. Related to sink in the same way that with is related to attach.

Usage

capture.output(..., file = NULL, append = FALSE)

Arguments

...  Expressions to be evaluated.
file  A file name or a connection, or NULL to return the output as a character vector. If the connection is not open, it will be opened initially and closed on exit.
append  logical. If file a file name or unopened connection, append or overwrite?

Details

An attempt is made to write output as far as possible to file if there is an error in evaluating the expressions, but for file = NULL all output will be lost.

Value

A character string (if file = NULL), or invisible NULL.

See Also

sink.textConnection

Examples

require(stats)
glmout <- capture.output(example(glm))
glmout[1:5]
capture.output(1+1, 2+2)
capture.output([1+1; 2+2])
## Not run:
## on Unix with enscript available
ps <- pipe("enscript -o tempout.ps","w")
changedFiles

`capture.output(example(glm), file = ps)`
`close(ps)`

```r
## End(Not run)
```

---

**changedFiles**

*Detect which files have changed*

**Description**

`fileSnapshot` takes a snapshot of a selection of files, recording summary information about each. `changedFiles` compares two snapshots, or compares one snapshot to the current state of the file system. The snapshots need not be the same directory; this could be used to compare two directories.

**Usage**

```r
capture.output(example(glm), file = ps)
```

```r
close(ps)
```

```r
## End(Not run)
```

```r
changedFiles(before, after, path = before$path, timestamp = before$timestamp,
  check.file.info = c("size", "isdir", "mode", "mtime"),
  md5sum = before$md5sum, digest = before$digest,
  full.names = before$full.names, ...)
```

```r
## S3 method for class 'fileSnapshot'
print(x, verbose = FALSE, ...)
```

```r
## S3 method for class 'changedFiles'
print(x, verbose = FALSE, ...)
```

**Arguments**

- **path**
  - character vector; the path(s) to record.

- **file.info**
  - logical; whether to record `file.info` values for each file.

- **timestamp**
  - character string or `NULL`; the name of a file to write at the time the snapshot is taken. This gives a quick test for modification, but may be unreliable; see the Details.

- **md5sum**
  - logical; whether MD5 summaries of each file should be taken as part of the snapshot.

- **digest**
  - a function or `NULL`; a function with header `function(filename)` which will take a vector of filenames and produce a vector of values of the same length, or a matrix with that number of rows.

- **full.names**
  - logical; whether full names (as in `list.files`) should be recorded. Must be `TRUE` if `length(path) > 1`.

- **...**
  - additional parameters to pass to `list.files` to control the set of files in the snapshots.
before, after objects produced by `fileSnapshot`; two snapshots to compare. If after is missing, a new snapshot of the current file system will be produced for comparison, using arguments recorded in before as defaults.

`check.file.info` character vector; which columns from `file.info` should be compared.

x the object to print.

verbose logical; whether to list all data when printing.

### Details

The `fileSnapshot` function uses `list.files` to obtain a list of files, and depending on the `file.info`, `md5sum`, and `digest` arguments, records information about each file.

The `changedFiles` function compares two snapshots.

If the `timestamp` argument to `fileSnapshot` is length 1, a file with that name is created. If it is length 1 in `changedFiles`, the `file_test` function is used to compare the age of all files common to both before and after it. This test may be unreliable: it compares the current modification time of the after files to the timestamp; that may not be the same as the modification time when the after snapshot was taken. It may also give incorrect results if the clock on the file system holding the timestamp differs from the one holding the snapshot files.

If the `check.file.info` argument contains a non-empty character vector, the indicated columns from the result of a call to `file.info` will be compared.

If `md5sum` is TRUE, `fileSnapshot` will call the `tools::md5sum` function to record the 32 byte MD5 checksum for each file, and `changedFiles` will compare the values. The `digest` argument allows users to provide their own digest function.

### Value

`fileSnapshot` returns an object of class "fileSnapshot". This is a list containing the fields:

- `info` a data frame whose rownames are the filenames, and whose columns contain the requested snapshot data
- `path` the normalized path from the call
- `timestamp, file.info, md5sum, digest, full.names` a record of the other arguments from the call
- `args` other arguments passed via ... to `list.files`.

`changedFiles` produces an object of class "changedFiles". This is a list containing

- `added, deleted, changed, unchanged` character vectors of filenames from the before and after snapshots, with obvious meanings
- `changes` a logical matrix with a row for each common file, and a column for each comparison test. TRUE indicates a change in that test.

`print` methods are defined for each of these types. The `print` method for "fileSnapshot" objects displays the arguments used to produce them, while the one for "changedFiles" displays the added, deleted and changed fields if non-empty, and a submatrix of the `changes` matrix containing all of the TRUE values.

dir.create(file.path(dir, "dir"))

# Take a snapshot
snapshot <- fileSnapshot(dir, timestamp = tempfile("timestamp"), md5sum=TRUE)

# Change one of the files.
writeBin(3L:4L, file.path(dir, "file2"))

# Display the detected changes. We may or may not see mtime change...
changedFiles(snapshot)
changedFiles(snapshot)$changes

chooseBioCmirror  Select a Bioconductor Mirror

Description

Interact with the user to choose a Bioconductor mirror.

Usage

chooseBioCmirror(graphics =getOption("menu.graphics"), ind = NULL)

Arguments

  graphics  logical. If true, use a graphical list: on Windows or the OS X GUI use a list
            box, and on a Unix-alike if package tcltk and an X server are available, use a
            Tk widget. Otherwise use a text menu.

  ind  Optional numeric value giving which entry to select.

Details

This sets the option "BioC_mirror": it needs to be used before a call to setRepositories.
In addition to the Bioconductor master site (in Seattle, USA), there currently are mirrors in Bethesda
(USA), Dortmund (Germany), Bergen (Norway) and Cambridge (UK).

Value

None: this function is invoked for its side effect of updating options("BioC_mirror").

See Also

setRepositories, chooseCRANmirror.
chooseCRANmirror

Select a CRAN Mirror

Description

Interact with the user to choose a CRAN mirror.

Usage

chooseCRANmirror(graphics = getOption("menu.graphics"), ind = NULL)

cranmirrors(all = FALSE, local.only = FALSE)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>graphics</td>
<td>Logical. If true, use a graphical list: on Windows or the OS X GUI use a list box, and on a Unix-alike if package tcltk and an X server are available, use a Tk widget. Otherwise use a text menu.</td>
</tr>
<tr>
<td>ind</td>
<td>Optional numeric value giving which entry to select.</td>
</tr>
<tr>
<td>all</td>
<td>Logical, get all known mirrors or only the ones flagged as OK.</td>
</tr>
<tr>
<td>local.only</td>
<td>Logical, try to get most recent list from CRAN or use file on local disk only.</td>
</tr>
</tbody>
</table>

Details

A list of mirrors is stored in file ‘R_HOME/doc/CRAN_mirrors.csv’, but first an on-line list of current mirrors is consulted, and the file copy used only if the on-line list is inaccessible.

This function was originally written to support a Windows GUI menu item, but is also called by contrib.url if it finds the initial dummy value of options("repos").

Value

None for chooseCRANmirror(), this function is invoked for its side effect of updating options("repos").

cranmirrors() returns a data frame with mirror information.

See Also

setRepositories, chooseBioCmirror, contrib.url.
**Description**

How to cite R and R packages in publications.

**Usage**

```r
citation(package = "base", lib.loc = NULL, auto = NULL)
readCitationFile(file, meta = NULL)
```

**Arguments**

- `package` a character string with the name of a single package. An error occurs if more than one package name is given.
- `lib.loc` a character vector with path names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
- `auto` a logical indicating whether the default citation auto-generated from the package ‘DESCRIPTION’ metadata should be used or not, or NULL (default), indicating that a ‘CITATION’ file is used if it exists, or an object of class "packageDescription" with package metadata (see below).
- `file` a file name.
- `meta` a list of package metadata as obtained by `packageDescription`, or NULL (the default).

**Details**

The R core development team and the very active community of package authors have invested a lot of time and effort in creating R as it is today. Please give credit where credit is due and cite R and R packages when you use them for data analysis.

Execute function `citation()` for information on how to cite the base R system in publications. If the name of a non-base package is given, the function either returns the information contained in the ‘CITATION’ file of the package or auto-generates citation information. In the latter case the package ‘DESCRIPTION’ file is parsed, the resulting citation object may be arbitrarily bad, but is quite useful (at least as a starting point) in most cases.

In R >= 2.14.0, one can use a ‘Authors@R’ field in ‘DESCRIPTION’ to provide (R code giving) a `person` object with a refined, machine-readable description of the package “authors” (in particular specifying their precise roles). Only those with an author role will be included in the auto-generated citation.

If only one reference is given, the print method for the object returned by `citation()` shows both a text version and a BibTeX entry for it, if a package has more than one reference then only the text versions are shown. The BibTeX versions can be obtained using function `toBibtex()` (see the examples below).

The ‘CITATION’ file of an R package should be placed in the ‘inst’ subdirectory of the package source. The file is an R source file and may contain arbitrary R commands including conditionals.
and computations. Function `readCitationFile()` is used by `citation()` to extract the information in ‘CITATION’ files. The file is sourced by the R parser in a temporary environment and all resulting bibliographic objects (specifically, of class "bibentry") are collected.

Traditionally, the ‘CITATION’ file contained zero or more calls to `citHeader`, then one or more calls to `citEntry`, and finally zero or more calls to `citFooter`, where in fact `citHeader` and `citFooter` are simply wrappers to `paste`, with their ... argument passed on to `paste` as is. The "bibentry" class makes for improved representation and manipulation of bibliographic information (in fact, the old mechanism is implemented using the new one), and one can write ‘CITATION’ files using the unified `bibentry` interface.

One can include an auto-generated package citation in the ‘CITATION’ file via `citation(auto = meta).

`readCitationFile` makes use of the Encoding element (if any) of `meta` to determine the encoding of the file.

### Value

An object inheriting from class "bibentry".

### See Also

`bibentry`

### Examples

```r
## the basic R reference
citation()

## references for a package -- might not have these installed
if(nchar(system.file(package = "lattice"))) citation("lattice")
if(nchar(system.file(package = "foreign"))) citation("foreign")

## extract the bibtex entry from the return value
x <- citation()
toBibtex(x)
```

---

**cite**

### Cite a bibliography entry.

**Description**

Cite a bibentry object in text. The `cite()` function uses the `cite()` function from the default `bibstyles` if present, or `citeNatbib()` if not. `citeNatbib()` uses a style similar to that used by the LaTeX package `natbib`.

**Usage**

```r
cite(keys, bib, ...)
citeNatbib(keys, bib, textual = FALSE, before = NULL, after = NULL,
mode = c("authoryear", "numbers", "super"),
abbreviate = TRUE, longnamesfirst = TRUE,
bibpunct = c("", ",", ":", ",", ",", ",", ",", ",", previous)
```
Arguments

keys A character vector of keys of entries to cite. May contain multiple keys in a single entry, separated by commas.
bib A "bibentry" object containing the list of documents in which to find the keys.
... Additional arguments to pass to the cite() function for the default style.
textual Produce a “textual” style of citation, i.e. what \citet would produce in LaTeX.
before Optional text to display before the citation.
after Optional text to display after the citation.
mode The “mode” of citation.
abbreviate Whether to abbreviate long author lists.
longnamesfirst If abbreviate == TRUE, whether to leave the first citation long.
bibpunct A vector of punctuation to use in the citation, as used in natbib. See the Details section.
previous A list of keys that have been previously cited, to be used when abbreviate == TRUE and longnamesfirst == TRUE

Details

Argument names are chosen based on the documentation for the LaTeX natbib package. See that documentation for the interpretation of the bibpunct entries.

The entries in bibpunct are as follows:

1. The left delimiter.
2. The right delimiter.
3. The separator between references within a citation.
4. An indicator of the “mode”: "n" for numbers, "s" for superscripts, anything else for author-year.
5. Punctuation to go between the author and year.
6. Punctuation to go between years when authorship is suppressed.

Note that if mode is specified, it overrides the mode specification in bibpunct[4]. Partial matching is used for mode.

The defaults for citeNatbib have been chosen to match the JSS style, and by default these are used in cite. See bibstyle for how to set a different default style.

Value

A single element character string is returned, containing the citation.

Bibliography Entries (Older Interface)

Description

Functionality for specifying bibliographic information in enhanced BibTeX style.

Usage

citEntry(entry, textVersion, header = NULL, footer = NULL, ...)
citHeader(...)
citFooter(...)

Arguments

- **entry**: a character string with a BibTeX entry type. See section **Entry Types** in bibentry for details.
- **textVersion**: a character string with a text representation of the reference.
- **header**: a character string with optional header text.
- **footer**: a character string with optional footer text.
- **...**: for citEntry, arguments of the form tag=value giving the fields of the entry, with tag and value the name and value of the field, respectively. See section **Entry Fields** in bibentry for details.

For citHeader and citFooter, character strings.

Value

citEntry produces an object of class "bibentry".

See Also

citation for more information about citing R and R packages and 'CITATION' files; bibentry for the newer functionality for representing and manipulating bibliographic information.
**close.socket**  
*Close a Socket*

**Description**
Closes the socket and frees the space in the file descriptor table. The port may not be freed immediately.

**Usage**
close.socket(socket, ...)

**Arguments**
socket A socket object
... further arguments passed to or from other methods.

**Value**
logical indicating success or failure

**Author(s)**
Thomas Lumley

**See Also**
make.socket, read.socket

---

**combn**  
*Generate All Combinations of n Elements, Taken m at a Time*

**Description**
Generate all combinations of the elements of \( x \) taken \( m \) at a time. If \( x \) is a positive integer, returns all combinations of the elements of seq(\( x \)) taken \( m \) at a time. If argument FUN is not NULL, applies a function given by the argument to each point. If simplify is FALSE, returns a list; otherwise returns an array, typically a matrix. ... are passed unchanged to the FUN function, if specified.

**Usage**
combn(x, m, FUN = NULL, simplify = TRUE, ...)

---
combn

Arguments

- **x**: vector source for combinations, or integer n for `x <- seq_len(n)`.
- **m**: number of elements to choose.
- **FUN**: function to be applied to each combination; default NULL means the identity, i.e., to return the combination (vector of length m).
- **simplify**: logical indicating if the result should be simplified to an array (typically a matrix); if FALSE, the function returns a list. Note that when simplify = TRUE as by default, the dimension of the result is simply determined from `FUN(1st combination)` (for efficiency reasons). This will badly fail if `FUN(u)` is not of constant length.
- ... optionally, further arguments to `FUN`.

Details

Factors x are accepted from R 3.1.0 (although coincidentally they worked for simplify = FALSE in earlier versions).

Value

A list or array, see the simplify argument above. In the latter case, the identity `dim(combn(n, m)) == c(m, choose(n, m))` holds.

Author(s)

Scott Chasalow wrote the original in 1994 for S; R package combinat and documentation by Vince Carey <stvjc@channing.harvard.edu>; small changes by the R core team, notably to return an array in all cases of simplify = TRUE, e.g., for `combn(5, 5)`.

References

See Also

choose for fast computation of the number of combinations. expand.grid for creating a data frame from all combinations of factors or vectors.

Examples

```r
combn(letters[1:4], 2)
(m <- combn(10, 5, min)) # minimum value in each combination
mm <- combn(15, 6, function(x) matrix(x, 2, 3))
stopifnot(round(choose(10, 5)) == length(m),
  c(2,3, round(choose(15, 6)))) == dim(mm))

## Different way of encoding points:
combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)

## Compute support points and (scaled) probabilities for a
## Multivariate-Hypergeometric(n = 3, N = c(4,3,2,1)) p.f.:
# table.mat(t(combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)))
```
## Assuring the identity

```r
for(n in 1:7)
  for(m in 0:n) stopifnot(is.array(cc <- combn(n, m)),
    dim(cc) == c(m, choose(n, m)))
```

---

### `compareVersion` 

**Compare Two Package Version Numbers**

**Description**

Compare two package version numbers to see which is later.

**Usage**

```r
compareVersion(a, b)
```

**Arguments**

- `a`, `b` Character strings representing package version numbers.

**Details**

R package version numbers are of the form `x.y-z` for integers `x`, `y` and `z`, with components after `x` optionally missing (in which case the version number is older than those with the components present).

**Value**

- `0` if the numbers are equal, `-1` if `b` is later and `1` if `a` is later (analogous to the C function `strcmp`).

**See Also**

`package_version`, `library.packageStatus`.

**Examples**

```r
compareVersion("1.0", "1.0-1")
compareVersion("7.2-0", "7.1-12")
```
Description

Compile given source files so that they can subsequently be collected into a shared object using `R CMD SHLIB` or an executable program using `R CMD LINK`.

Usage

```
R CMD COMPILE [options] srcfiles
```

Arguments

- **srcfiles**: A list of the names of source files to be compiled. Currently, C, C++, Objective C, Objective C++ and Fortran are supported; the corresponding files should have the extensions `.c`, `.cc` (or `.cpp`), `.m`, `.mm` (or `.M`), `.f` and `.f90` or `.f95`, respectively.
- **options**: A list of compile-relevant settings, or for obtaining information about usage and version of the utility.

Details

`R CMD SHLIB` can both compile and link files into a shared object: since it knows what run-time libraries are needed when passed C++, Fortran and Objective C(++) sources, passing source files to `R CMD SHLIB` is more reliable.

Ratfor is not supported. If you have Ratfor source code, you need to convert it to FORTRAN. (On some Solaris systems mixing Ratfor and FORTRAN code will work.)

Objective C and Objective C++ support is optional and will work only if the corresponding compilers were available at `R` configure time: their main usage is on OS X.

Compilation arranges to include the paths to the `R` public C/C++ headers.

As this compiles code suitable for incorporation into a shared object, it generates PIC code: that might occasionally be undesirable for the main code of an executable program.

This is a make-based facility, so will not compile a source file if a newer corresponding `.o` file is present.

Note

Some binary distributions of `R` have `COMPILE` in a separate bundle, e.g. an `R-devel` RPM.

This is not available on Windows.

See Also

`LINK`, `SHLIB`, `dyn.load`; the section on “Customizing compilation under Unix” in “R Administration and Installation” (see the ‘doc/manual’ subdirectory of the `R` source tree).
contrib.url  
Find Appropriate Paths in CRAN-like Repositories

Description

contrib.url adds the appropriate type-specific path within a repository to each URL in repos.

Usage

contrib.url(repos, type = getOption("pkgType"))

Arguments

repos  character vector, the base URL(s) of the repositories to use.
type  character string, indicating which type of packages: see install.packages.

Details

If type = "both" this will use the source repository.

Value

A character vector of the same length as repos.

See Also

setRepositories to set options("repos"), the most common value used for argument repos. available.packages, download.packages, install.packages.

The ‘R Installation and Administration’ manual for how to set up a repository.

count.fields  
Count the Number of Fields per Line

Description

count.fields counts the number of fields, as separated by sep, in each of the lines of file read.

Usage

count.fields(file, sep = "", quote = "\"\", skip = 0,
blank.lines.skip = TRUE, comment.char = ")
create.post

Ancillary Function for Preparing Emails and Postings

Description

An ancillary function used by bug.report and help.request to prepare emails for submission to package maintainers or to R mailing lists.

Usage

create.post(instructions = character(), description = "post", subject = "", method = getOption("mailer"), address = "the relevant mailing list", caddress = getOption("ccaddress", ""), filename = "R.post", info = character())
create.post

Arguments

instructions Character vector of instructions to put at the top of the template email.
description Character string: a description to be incorporated into messages.
subject Subject of the email. Optional except for the "mailto" method.
method Submission method, one of "none", "mailto", "gnudoit", "ess" or (Unix only) "mailx". See 'Details'.
address Recipient’s email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed).
ccaddress Optional email address for copies with the "mailto" and "mailto" methods. Use ccaddress = "" for no copy.
filename Filename to use for setting up the email (or storing it when method is "none" or sending mail fails).
info character vector of information to include in the template email below the 'please do not edit the information below' line.

Details

What this does depends on the method. The function first creates a template email body.

none A file editor (see file.edit) is opened with instructions and the template email. When this returns, the completed email is in file file ready to be read/pasted into an email program.

mailto This opens the default email program with a template email (including address, Cc: address and subject) for you to edit and send.
This works where default mailers are set up (usual on OS X and Windows, and where xdg-open is available and configured on other Unix-alikes: if that fails it tries the browser set by R_BROWSER).
This is the ‘factory-fresh’ default method.

mailx (Unix-alikes only.) A file editor (see file.edit) is opened with instructions and the template email. When this returns, it is mailed using a Unix command line mail utility such as mailx, to the address (and optionally, the Cc: address) given.

gnudoit An (X)emacs mail buffer is opened for the email to be edited and sent: this requires the gnudoit program to be available. Currently subject is ignored.

ess The body of the template email is sent to stdout.

Value

Invisible NULL.

See Also

bug.report, help.request.
Description

Loads specified data sets, or list the available data sets.

Usage

data(..., list = character(), package = NULL, lib.loc = NULL, verbose =getOption("verbose"), envir = .GlobalEnv)

Arguments

... literal character strings or names.
list a character vector.
package a character vector giving the package(s) to look in for data sets, or NULL.
By default, all packages in the search path are used, then the ‘data’ subdirectory
(if present) of the current working directory.
lib.loc a character vector of directory names of R libraries, or NULL. The default value
of NULL corresponds to all libraries currently known.
verbose a logical. If TRUE, additional diagnostics are printed.
envir the environment where the data should be loaded.

Details

Currently, four formats of data files are supported:

1. files ending ‘.R’ or ‘.r’ are source()d in, with the R working directory changed temporarily
to the directory containing the respective file. (data ensures that the utils package is attached,
in case it had been run via utils:::data.)
2. files ending ‘.RData’ or ‘.rda’ are loaded.
3. files ending ‘.tab’, ‘.txt’ or ‘.TXT’ are read using read.table(..., header = TRUE), and
hence result in a data frame.
4. files ending ‘.csv’ or ‘.CSV’ are read using read.table(..., header = TRUE, sep = ";")
and also result in a data frame.

If more than one matching file name is found, the first on this list is used. (Files with extensions
’.txt’, ‘.tab’ or ‘.csv’ can be compressed, with or without further extension ‘.gz’, ‘.bz2’ or
’.xz’.)

The data sets to be loaded can be specified as a set of character strings or names, or as the character
vector list, or as both.

For each given data set, the first two types (‘.R’ or ‘.r’, and ‘.RData’ or ‘.rda’ files) can create
several variables in the load environment, which might all be named differently from the data set.
The third and fourth types will always result in the creation of a single variable with the same name
(without extension) as the data set.

If no data sets are specified, data lists the available data sets. It looks for a new-style data index
in the ‘Meta’ or, if this is not found, an old-style ‘@Index’ file in the ‘data’ directory of each
specified package, and uses these files to prepare a listing. If there is a ‘data’ area but no index, available data files for loading are computed and included in the listing, and a warning is given: such packages are incomplete. The information about available data sets is returned in an object of class "packageIQR". The structure of this class is experimental. Where the datasets have a different name from the argument that should be used to retrieve them the index will have an entry like beaver1 (beavers) which tells us that dataset beaver1 can be retrieved by the call data(beaver).

If lib.loc and package are both NULL (the default), the data sets are searched for in all the currently loaded packages then in the ‘data’ directory (if any) of the current working directory.

If lib.loc = NULL but package is specified as a character vector, the specified package(s) are searched for first amongst loaded packages and then in the default library/ies (see .libPaths).

If lib.loc is specified (and not NULL), packages are searched for in the specified library/ies, even if they are already loaded from another library.

To just look in the ‘data’ directory of the current working directory, set package = character(0) (and lib.loc = NULL, the default).

Value
A character vector of all data sets specified, or information about all available data sets in an object of class "packageIQR" if none were specified.

Good practice

data() was originally intended to allow users to load datasets from packages for use in their examples, and as such it loaded the datasets into the workspace .GlobalEnv. This avoided having large datasets in memory when not in use. That need has been almost entirely superseded by lazy-loading of datasets.

The ability to specify a dataset by name (without quotes) is a convenience: in programming the datasets should be specified by character strings (with quotes).

Use of data within a function without an envir argument has the almost always undesirable side-effect of putting an object in the user’s workspace (and indeed, of replacing any object of that name already there). It would almost always be better to put the object in the current evaluation environment by data(..., envir = environment(())). However, two alternatives are usually preferable, both described in the ‘Writing R Extensions’ manual.

- For sets of data, set up a package to use lazy-loading of data.
- For objects which are system data, for example lookup tables used in calculations within the function, use a file ‘R/sysdata.rda’ in the package sources or create the objects by R code at package installation time.

A sometimes important distinction is that the second approach places objects in the namespace but the first does not. So if it is important that the function sees mytable as an object from the package, it is system data and the second approach should be used. In the unusual case that a package uses a lazy-loaded dataset as a default argument to a function, that needs to be specified by ::, e.g., survival::survexp.us.

Note

One can take advantage of the search order and the fact that a ‘.R’ file will change directory. If raw data are stored in ‘mydata.txt’ then one can set up ‘mydata.R’ to read ‘mydata.txt’ and pre-process it, e.g., using transform. For instance one can convert numeric vectors to factors with the appropriate labels. Thus, the ‘.R’ file can effectively contain a metadata specification for the plaintext formats.
See Also

`help` for obtaining documentation on data sets, `save` for creating the second (`.rda`) kind of data, typically the most efficient one.

The ‘Writing R Extensions’ for considerations in preparing the ‘data’ directory of a package.

Examples

```r
require(utils)
data()          # list all available data sets
try(data(package = "rpart"))  # list the data sets in the rpart package
data(USArrests, "VADeaths") # load the data sets 'USArrests' and 'VADeaths'
## Not run: ## Alternatively
ds <- c("USArrests", "VADeaths"); data(list = ds)
## End(Not run)
help(USArrests)  # give information on data set 'USArrests'
```

---

**dataentry**

*Spreadsheet Interface for Entering Data*

**Description**

A spreadsheet-like editor for entering or editing data.

**Usage**

```r
data.entry(..., Modes = NULL, Names = NULL)
dataentry(data, modes)
de(..., Modes = list(), Names = NULL)
```

**Arguments**

- `...` A list of variables: currently these should be numeric or character vectors or list containing such vectors.
- `Modes` The modes to be used for the variables.
- `Names` The names to be used for the variables.
- `data` A list of numeric and/or character vectors.
- `modes` A list of length up to that of data giving the modes of (some of) the variables. `list()` is allowed.

**Details**

The data entry editor is only available on some platforms and GUIs. Where available it provides a means to visually edit a matrix or a collection of variables (including a data frame) as described in the Notes section.

data.entry has side effects, any changes made in the spreadsheet are reflected in the variables. The functions `de`, `de ncols`, `de .setup` and `de restore` are designed to help achieve these side effects. If the user passes in a matrix, `X` say, then the matrix is broken into columns before `dataentry` is called. Then on return the columns are collected and glued back together and the result assigned to the variable `X`. If you don’t want this behaviour use `dataentry` directly.
The primitive function is `dataentry`. It takes a list of vectors of possibly different lengths and modes (the second argument) and opens a spreadsheet with these variables being the columns. The columns of the dataentry window are returned as vectors in a list when the spreadsheet is closed.

`de.ncols` counts the number of columns which are supplied as arguments to `data.entry`. It attempts to count columns in lists, matrices and vectors. `de.setup` sets things up so that on return the columns can be regrouped and reassigned to the correct name. This is handled by `de.restore`.

**Value**

de and `dataentry` return the edited value of their arguments. `data.entry` invisibly returns a vector of variable names but its main value is its side effect of assigning new version of those variables in the user’s workspace.

**Resources**

The data entry window responds to X resources of class `R.dataentry`. Resources `foreground`, `background` and `geometry` are utilized.

**Note**

The details of interface to the data grid may differ by platform and GUI. The following description applies to the X11-based implementation under Unix.

You can navigate around the grid using the cursor keys or by clicking with the (left) mouse button on any cell. The active cell is highlighted by thickening the surrounding rectangle. Moving to the right or down will scroll the grid as needed: there is no constraint to the rows or columns currently in use.

There are alternative ways to navigate using the keys. Return and (keypad) Enter and LineFeed all move down. Tab moves right and Shift-Tab move left. Home moves to the top left.

PageDown or Control-F moves down a page, and PageUp or Control-B up by a page. End will show the last used column and the last few rows used (in any column).

Using any other key starts an editing process on the currently selected cell: moving away from that cell enters the edited value whereas Esc cancels the edit and restores the previous value. When the editing process starts the cell is cleared. In numerical columns (the default) only letters making up a valid number (including `MNee`) are accepted, and entering an invalid edited value (such as blank) enters `NA` in that cell. The last entered value can be deleted using the BackSpace or Del(ete) key. Only a limited number of characters (currently 29) can be entered in a cell, and if necessary only the start or end of the string will be displayed, with the omissions indicated by `>` or `<. (The start is shown except when editing.)

Entering a value in a cell further down a column than the last used cell extends the variable and fills the gap (if any) by `NA`s (not shown on screen).

The column names can only be selected by clicking in them. This gives a popup menu to select the column type (currently Real (numeric) or Character) or to change the name. Changing the type converts the current contents of the column (and converting from Character to Real may generate `NA`s.) If changing the name is selected the header cell becomes editable (and is cleared). As with all cells, the value is entered by moving away from the cell by clicking elsewhere or by any of the keys for moving down (only).

New columns are created by entering values in them (and not by just assigning a new name). The mode of the column is auto-detected from the first value entered: if this is a valid number it gives a numeric column. Unused columns are ignored, so adding data in `var5` to a three-column grid adds one extra variable, not two.
The Copy button copies the currently selected cell: paste copies the last copied value to the current cell, and right-clicking selects a cell and copies in the value. Initially the value is blank, and attempts to paste a blank value will have no effect.

Control-L will refresh the display, recalculating field widths to fit the current entries.

In the default mode the column widths are chosen to fit the contents of each column, with a default of 10 characters for empty columns. you can specify fixed column widths by setting option `cellwidth` to the required fixed width (in characters). (set it to zero to return to variable widths). The displayed width of any field is limited to 600 pixels (and by the window width).

See Also

`vi, edit`: edit uses `dataentry` to edit data frames.

Examples

```r
# call data entry with variables x and y
## Not run: data.entry(x, y)
```

---

### Description

Functions to dump the evaluation environments (frames) and to examine dumped frames.

### Usage

```r
dump.frames(dump.to = "last.dump", to.file = FALSE)
d Debugger(dump = last.dump)
```

### Arguments

- `dump.to` a character string. The name of the object or file to dump to.
- `to.file` logical. Should the dump be to an R object or to a file?
- `dump` An R dump object created by `dump.frames`.

### Details

To use post-mortem debugging, set the option `error` to be a call to `dump.frames`. By default this dumps to an R object `last.dump` in the workspace, but it can be set to dump to a file (a dump of the object produced by a call to `save`). The dumped object contain the call stack, the active environments and the last error message as returned by `geterrmessage`.

When dumping to file, `dump.to` gives the name of the dumped object and the file name has `.rda` appended.

A dump object of class "dump.frames" can be examined by calling `debugger`. This will give the error message and a list of environments from which to select repeatedly. When an environment is selected, it is copied and the `browser` called from within the copy. Note that not all the information in the original frame will be available, e.g. promises which have not yet been evaluated and the contents of any ... argument.

If `dump.frames` is installed as the error handler, execution will continue even in non-interactive sessions. See the examples for how to dump and then quit.
Value

Invisible NULL.

Note

Functions such as `sys.parent` and `environment` applied to closures will not work correctly inside debugger.

If the error occurred when computing the default value of a formal argument the debugger will report "recursive default argument reference" when trying to examine that environment.

Of course post-mortem debugging will not work if R is too damaged to produce and save the dump, for example if it has run out of workspace.

References

See Also

`browser` for the actions available at the Browse prompt.

`options` for setting error options; `recover` is an interactive debugger working similarly to `debugger` but directly after the error occurs.

Examples

```r
## Not run:
options(error = quote(dump.frames("testdump", TRUE)))

f <- function() {
  g <- function() stop("test dump.frames")
  g()
}
f()  # will generate a dump on file "testdump.rda"
options(error = NULL)

## possibly in another R session
load("testdump.rda")
debugger(testdump)
Available environments had calls:
1: f()
2: g()
3: stop("test dump.frames")

Enter an environment number, or 0 to exit
Selection: 1
Browsing in the environment with call:
f()
Called from: debugger.look(ind)
Browse[1]> ls()
[1] "g"
Browse[1]> g
function() stop("test dump.frames")
<environment: 759818>
Browse[1]>
```
Available environments had calls:
1: f()
2: g()
3: stop("test dump.frames")

Enter an environment number, or 0 to exit
Selection: 0

## A possible setting for non-interactive sessions
options(error = quote({dump.frames(to.file = TRUE); q(status = 1)}))

## End(Not run)

demo

Demonstrations of R Functionality

Description
demo is a user-friendly interface to running some demonstration R scripts. demo() gives the list of available topics.

Usage
demo(topic, package = NULL, lib.loc = NULL,
character.only = FALSE, verbose = getOption("verbose"),
echo = TRUE, ask = getOption("demo.ask"),
encoding = getOption("encoding"))

Arguments
topic the topic which should be demonstrated, given as a name or literal character string, or a character string, depending on whether character.only is FALSE (default) or TRUE. If omitted, the list of available topics is displayed.
package a character vector giving the packages to look into for demos, or NULL. By default, all packages in the search path are used.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
character.only logical; if TRUE, use topic as character string.
verbose a logical. If TRUE, additional diagnostics are printed.
echo a logical. If TRUE, show the R input when sourcing.
ask a logical (or "default") indicating if devAskNewPage(ask = TRUE) should be called before graphical output happens from the demo code. The value "default" (the factory-fresh default) means to ask if echo == TRUE and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the demo code. If this is evaluated to TRUE and the session is interactive, the user is asked to press RETURN to start.
encoding See source. If the package has a declared encoding, that takes preference.
Details

If no topics are given, demo lists the available demos. The corresponding information is returned in an object of class "packageIQR".

See Also

source and devAskNewPage which are called by demo.

Examples

demo() # for attached packages

## All available demos:
demo(package = .packages(all.available = TRUE))

## Display a demo, pausing between pages
demo(lm.glm, package = "stats", ask = TRUE)

## Display it without pausing
demo(lm.glm, package = "stats", ask = FALSE)

## Not run:
ch <- "scoping"
demo(ch, character = TRUE)

## End(Not run)

## Find the location of a demo
system.file("demo", "lm.glm.R", package = "stats")

download.file

Description

This function can be used to download a file from the Internet.

Usage

download.file(url, destfile, method, quiet = FALSE, mode = "w",
cacheOK = TRUE,
extra =getOption("download.file.extra"))

Arguments

url A character string naming the URL of a resource to be downloaded.
destfile A character string with the name where the downloaded file is saved. Tilde-expansion is performed.
method  Method to be used for downloading files. Currently download methods "internal", "wget", "curl" and "lynx" (deprecated) are available, and there is a value "auto": see ‘Details’ and ‘Note’. The method can also be set through the option "download.file.method": see options().

quiet  If TRUE, suppress status messages (if any), and the progress bar.

mode  character. The mode with which to write the file. Useful values are "w", "wb" (binary), "a" (append) and "ab". Only used for the "internal" method.

cacheOK  logical. Is a server-side cached value acceptable? Implemented for the "internal", "wget" and "curl" methods.

extra  character vector of additional command-line arguments for the "wget", "curl" and "lynx" methods.

Details

The function download.file can be used to download a single file as described by url from the internet and store it in destfile. The url must start with a scheme such as 'http://', 'ftp://', or 'file://'.

If method = "auto" is chosen (the default), the internal method is chosen for 'file:///' URLs, and for the others provided capabilities("http/ftp") is true (which it almost always is). Otherwise methods "wget", "curl" and "lynx" are tried in turn.

For methods "wget", "curl" and "lynx" a system call is made to the tool given by method, and the respective program must be installed on your system and be in the search path for executables. They will block all other activity on the R process until they complete: this may make a GUI unresponsive.

cacheOK = FALSE is useful for 'http://' URLs, and will attempt to get a copy directly from the site rather than from an intermediate cache. It is used by available.packages.

The remaining details apply to method "internal" only.

Note that 'https://' URLs are not supported by the internal method.

See url for how 'file:///' URLs are interpreted, especially on Windows. This function does decode encoded URLs.

The timeout for many parts of the transfer can be set by the option timeout which defaults to 60 seconds.

The level of detail provided during transfer can be set by the quiet argument and the internet.info option. The details depend on the platform and scheme, but setting internet.info to 0 gives all available details, including all server responses. Using 2 (the default) gives only serious messages, and 3 or more suppresses all messages.

A progress bar tracks the transfer. If the file length is known, an equals sign represents 2% of the transfer completed: otherwise a dot represents 10Kb.

Code written to download binary files must use mode = "wb", but the problems incurred by a text transfer will only be seen on Windows.

Value

An (invisible) integer code, 0 for success and non-zero for failure. For the "wget" and "curl" methods this is the status code returned by the external program. The "internal" method can return 1, but will in most cases throw an error.
Setting Proxies

This applies to the internal code only. Proxies can be specified via environment variables. Setting "no_proxy" to "]*" stops any proxy being tried. Otherwise the setting of "http_proxy" or "ftp_proxy" (or failing that, the all upper-case version) is consulted and if non-empty used as a proxy site. For FTP transfers, the username and password on the proxy can be specified by "ftp_proxy_user" and "ftp_proxy_password". The form of "http_proxy" should be "http://proxy.dom.com/" or "http://proxy.dom.com:8080/" where the port defaults to 80 and the trailing slash may be omitted. For "ftp_proxy" use the form "ftp://proxy.dom.com:3128/" where the default port is 21. These environment variables must be set before the download code is first used: they cannot be altered later by calling Sys.setenv.

Usernames and passwords can be set for HTTP proxy transfers via environment variable http_proxy_user in the form user:passwd. Alternatively, http_proxy can be of the form "http://user:pass@proxy.dom.com:8080/" for compatibility with wget. Only the HTTP/1.0 basic authentication scheme is supported.

Note

Files of more than 2GB are supported on 64-bit builds of R; they may be truncated on some 32-bit builds.

Method "wget" is mainly for historical compatibility, but it and "curl" can be used for URLs (e.g., 'https://' URLs or those that use cookies) which the internal method does not support.

Method "wget" can be used with proxy firewalls which require user/password authentication if proper values are stored in the configuration file for wget.

wget (http://www.gnu.org/software/wget/) is commonly installed on Unix-alikes (but not OS X). Windows binaries are available from Cygwin, gnuwin32 and elsewhere.

curl (http://curl.haxx.se/) is installed on OS X and commonly on Unix-alikes. Windows binaries are available at that URL.

Use of lynx (http://lynx.browser.org/) is of historical interest and now deprecated.

Contributed package RCurl provides more comprehensive facilities to download from URLs.

download.packages Download Packages from CRAN-like Repositories

Description

These functions can be used to automatically compare the version numbers of installed packages with the newest available version on the repositories and update outdated packages on the fly.
download.packages

Usage

download.packages(pkgs, destdir, available = NULL,
repos = getOption("repos"),
contriburl = contrib.url(repos, type),
method, type = getOption("pkgType"), ...)

Arguments

pkgs character vector of the names of packages whose latest available versions should be downloaded from the repositories.
destdir directory where downloaded packages are to be stored.
available an object as returned by available.packages listing packages available at the repositories, or NULL which makes an internal call to available.packages.
repos character vector, the base URL(s) of the repositories to use, i.e., the URL of the CRAN master such as "http://cran.r-project.org" or its Statlib mirror, "http://lib.stat.cmu.edu/R/CRAN".
contriburl URL(s) of the contrib sections of the repositories. Use this argument only if your repository mirror is incomplete, e.g., because you burned only the 'contrib' section on a CD. Overrides argument repos.
method Download method, see download.file.
type character string, indicate which type of packages: see install.packages.
... additional arguments to be passed to download.file.

Details
download.packages takes a list of package names and a destination directory, downloads the newest versions and saves them in destdir. If the list of available packages is not given as argument, it is obtained from repositories. If a repository is local, i.e. the URL starts with "file: ", then the packages are not downloaded but used directly. Both "file:" and "file:///" are allowed as prefixes to a file path. Use the latter only for URLs: see url for their interpretation. (Other forms of 'file:///' URLs are not supported.)

Value

A two-column matrix of names and destination file names of those packages successfully downloaded. If packages are not available or there is a problem with the download, suitable warnings are given.

See Also

available.packages, contrib.url.
The main use is by install.packages.
See download.file for how to handle proxies and other options to monitor file transfers.

The ‘R Installation and Administration’ manual for how to set up a repository.
**Description**

Invoke a text editor on an R object.

**Usage**

```r
## Default S3 method:
edit(name = NULL, file = "", title = NULL,
editor = getOption("editor"), ...)
```

```r
v(name = NULL, file = "")
emacs(name = NULL, file = "")
pico(name = NULL, file = "")
xemacs(name = NULL, file = "")
xedit(name = NULL, file = ")
```

**Arguments**

- `name` a named object that you want to edit. If `name` is missing then the file specified by `file` is opened for editing.
- `file` a string naming the file to write the edited version to.
- `title` a display name for the object being edited.
- `editor` usually a string naming the text editor you want to use. On Unix the default is set from the environment variables `EDITOR` or `VISUAL` if either is set, otherwise `vi` is used. On Windows it defaults to "internal", the script editor. On the OS X GUI the argument is ignored and the document editor is always used.
- `editor` can also be a function, in which case it is called with the arguments `name`, `file`, and `title`. Note that such a function will need to independently implement all desired functionality.
- `...` further arguments to be passed to or from methods.

**Details**

`edit` invokes the text editor specified by `editor` with the object `name` to be edited. It is a generic function, currently with a default method and one for data frames and matrices.

`data.entry` can be used to edit data, and is used by `edit` to edit matrices and data frames on systems for which `data.entry` is available.

It is important to realize that `edit` does not change the object called `name`. Instead, a copy of `name` is made and it is that copy which is changed. Should you want the changes to apply to the object `name` you must assign the result of `edit` to `name`. (Try `fix` if you want to make permanent changes to an object.)

In the form `edit(name)`, `edit` deparses `name` into a temporary file and invokes the editor `editor` on this file. Quitting from the editor causes `file` to be parsed and that value returned. Should an error occur in parsing, possibly due to incorrect syntax, no value is returned. Calling `edit()`, with no arguments, will result in the temporary file being reopened for further editing.
Note that deparsing is not perfect, and the object recreated after editing can differ in subtle ways from that deparsed: see `dput` and `.deparseOpts`. (The deparse options used are the same as the defaults for `dump`.) Editing a function will preserve its environment. See `edit.data.frame` for further changes that can occur when editing a data frame or matrix.

Currently only the internal editor in Windows makes use of the `title` option; it displays the given name in the window header.

**Note**

The functions `vi`, `emacs`, `pico`, `xemacs`, `xedit` rely on the corresponding editor being available and being on the path. This is system-dependent.

**See Also**

`edit.data.frame`, `data.entry`, `fix`.

**Examples**

```r
## Not run:
# use xedit on the function mean and assign the changes
mean <- edit(mean, editor = "xedit")

# use vi on mean and write the result to file mean.out
vi(mean, file = "mean.out")

## End(Not run)
```

---

**edit.data.frame**  
**Edit Data Frames and Matrices**

**Description**

Use data editor on data frame or matrix contents.

**Usage**

```r
## S3 method for class 'data.frame'
edit(name, factor.mode = c("character", "numeric"),
     edit.row.names = any(row.names(name) != 1:nrow(name)), ...)

## S3 method for class 'matrix'
edit(name, edit.row.names = !is.null(dn[[1]]), ...)
```

**Arguments**

- **name**: A data frame or (numeric, logical or character) matrix.
- **factor.mode**: How to handle factors (as integers or using character levels) in a data frame.
- **edit.row.names**: logical. Show the row names (if they exist) be displayed as a separate editable column? It is an error to ask for this on a matrix with NULL row names.
- **...**: further arguments passed to or from other methods.
Details

At present, this only works on simple data frames containing numeric, logical or character vectors and factors, and numeric, logical or character matrices. Any other mode of matrix will give an error, and a warning is given when the matrix has a class (which will be discarded).

Data frame columns are coerced on input to character unless numeric (in the sense of \texttt{is.numeric}), logical or factor. A warning is given when classes are discarded. Special characters (tabs, non-printing ASCII, etc.) will be displayed as escape sequences.

Factors columns are represented in the spreadsheet as either numeric vectors (which are more suitable for data entry) or character vectors (better for browsing). After editing, vectors are padded with \texttt{NA} to have the same length and factor attributes are restored. The set of factor levels can not be changed by editing in numeric mode; invalid levels are changed to \texttt{NA} and a warning is issued. If new factor levels are introduced in character mode, they are added at the end of the list of levels in the order in which they encountered.

It is possible to use the data-editor’s facilities to select the mode of columns to swap between numerical and factor columns in a data frame. Changing any column in a numerical matrix to character will cause the result to be coerced to a character matrix. Changing the mode of logical columns is not supported.

For a data frame, the row names will be taken from the original object if \texttt{edit.row.names = FALSE} and the number of rows is unchanged, and from the edited output if \texttt{edit.row.names = TRUE} and there are no duplicates. (If the \texttt{row.names} column is incomplete, it is extended by entries like \texttt{row223.}) In all other cases the row names are replaced by \texttt{seq(length = n rows)}.

For a matrix, colnames will be added (of the form \texttt{col7}) if needed. The rownames will be taken from the original object if \texttt{edit.row.names = FALSE} and the number of rows is unchanged (otherwise \texttt{NULL}), and from the edited output if \texttt{edit.row.names = TRUE}. (If the \texttt{row.names} column is incomplete, it is extended by entries like \texttt{row223.})

Editing a matrix or data frame will lose all attributes apart from the row and column names.

Value

The edited data frame or matrix.

Note

\texttt{fix(dataframe)} works for in-place editing by calling this function.

If the data editor is not available, a dump of the object is presented for editing using the default method of \texttt{edit}.

At present the data editor is limited to 65535 rows.

data.entry, edit
**Examples**

```r
## Not run:
edit(InsectSprays)
edit(InsectSprays, factor.mode = "numeric")

## End(Not run)
```

---

**Description**

Run all the R code from the Examples part of R’s online help topic topic with two possible exceptions, dontrun and dontshow, see ‘Details’ below.

**Usage**

```r
example(topic, package = NULL, lib.loc = NULL,
         character.only = FALSE, give.lines = FALSE, local = FALSE,
         echo = TRUE, verbose = getOption("verbose"),
         setRNG = FALSE, ask = getOption("example.ask"),
         prompt.prefix = abbreviate(topic, 6),
         run.dontrun = FALSE)
```

**Arguments**

- `topic`: name or literal character string: the online help topic the examples of which should be run.
- `package`: a character vector giving the package names to look into for the topic, or NULL (the default), when all packages on the search path are used.
- `lib.loc`: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
- `character.only`: a logical indicating whether topic can be assumed to be a character string.
- `give.lines`: logical: if TRUE, the lines of the example source code are returned as a character vector.
- `local`: logical: if TRUE evaluate locally, if FALSE evaluate in the workspace.
- `echo`: logical: if TRUE, show the R input when sourcing.
- `verbose`: logical: if TRUE, show even more when running example code.
- `setRNG`: logical or expression; if not FALSE, the random number generator state is saved, then initialized to a specified state, the example is run and the (saved) state is restored. `setRNG = TRUE` sets the same state as R CMD check does for running a package’s examples. This is currently equivalent to `setRNG = (RNGkind("default", "default"); set.seed(1))`.  
- `ask`: logical (or "default") indicating if dev AskNewPage(ask = TRUE) should be called before graphical output happens from the example code. The value "default" (the factory-fresh default) means to ask if echo == TRUE and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the example code.
example

prompt.prefix  character; prefixes the prompt to be used if `echo = TRUE`
run.dontrun logical indicating that `dontrun` should be ignored.

Details

If `lib.loc` is not specified, the packages are searched for amongst those already loaded, then in the libraries given by `.libPaths()`. If `lib.loc` is specified, packages are searched for only in the specified libraries, even if they are already loaded from another library. The search stops at the first package found that has help on the topic.

An attempt is made to load the package before running the examples, but this will not replace a package loaded from another location.

If `local = TRUE` objects are not created in the workspace and so not available for examination after `example` completes: on the other hand they cannot overwrite objects of the same name in the workspace.

As detailed in the manual *Writing R Extensions*, the author of the help page can markup parts of the examples for two exception rules `dontrun` encloses code that should not be run.

dontshow encloses code that is invisible on help pages, but will be run both by the package checking tools, and the `example()` function. This was previously `testonly`, and that form is still accepted.

Value

The value of the last evaluated expression, unless `give.lines` is true, where a `character` vector is returned.

demo

Examples

e.example(InsectSprays)
## force use of the standard package 'stats':
e.example("smooth", package = "stats", lib.loc = .Library)

## set RNG *before* example as when R CMD check is run:

r1 <- e.example(quantile, setRNG = TRUE)
x1 <- rnorm(1)
u <- runif(1)
## identical random numbers
r2 <- e.example(quantile, setRNG = TRUE)
x2 <- rnorm(1)
stopifnot(identical(r1, r2))
## but x1 and x2 differ since the RNG state from before example()
## differs and is restored!
x1; x2
file.edit

## Exploring examples code:
## How large are the examples of "lm...()" functions?
`lmex <- sapply(apropos("lm", mode = "function"),
    example, character.only = TRUE, give.lines = TRUE)
sapply(lmex, length)

## Edit One or More Files

**Description**
Edit one or more files in a text editor.

**Usage**
`file.edit(..., title = file, editor = getOption("editor"),
    fileEncoding = "")`

**Arguments**
- `...`: one or more character vectors containing the names of the files to be displayed. These will be tilde-expanded: see `path.expand`.
- `title`: the title to use in the editor; defaults to the filename.
- `editor`: the text editor to be used. See ‘Details’.
- `fileEncoding`: the encoding to assume for the file: the default is to assume the native encoding. See the ‘Encoding’ section of the help for `file`.

**Details**
The behaviour of this function is very system dependent. Currently files can be opened only one at a time on Unix; on Windows, the internal editor allows multiple files to be opened, but has a limit of 50 simultaneous edit windows.

The `title` argument is used for the window caption in Windows, and is currently ignored on other platforms.

Any error in re-encoding the files to the native encoding will cause the function to fail.

The default for `editor` is system-dependent. On Windows it defaults to "internal", the script editor, and in the OS X GUI the document editor is used whatever the value of `editor`. On Unix the default is set from the environment variables `EDITOR` or `VISUAL` if either is set, otherwise `vi` is used.

**See Also**
`files, file.show, edit, fix`.

**Examples**
```r
## Not run:
# open two R scripts for editing
file.edit("script1.R", "script2.R")

## End(Not run)
```
**file_test**  
*Shell-style Tests on Files*

**Description**
Utility for shell-style file tests.

**Usage**

```
file_test(op, x, y)
```

**Arguments**

- `op`: a character string specifying the test to be performed. Unary tests (only x is used) are "-f" (existence and not being a directory), "-d" (existence and directory) and "-x" (executable as a file or searchable as a directory). Binary tests are "-nt" (strictly newer than, using the modification dates) and "-ot" (strictly older than): in both cases the test is false unless both files exist.
- `x, y`: character vectors giving file paths.

**Details**

'Existence' here means being on the file system and accessible by the *stat* system call (or a 64-bit extension) – on a Unix-alike this requires execute permission on all of the directories in the path that leads to the file, but no permissions on the file itself.

For the meaning of "-x" on Windows see *file.access*.

**See Also**

- *file.exists* which only tests for existence (test -e on some systems) but not for not being a directory.
- *file.path, file.info*

**Examples**

```
dir <- file.path(R.home(), "library", "stats")
file_test("-d", dir)
file_test("-nt", file.path(dir, "R"), file.path(dir, "demo"))
```

---

**findLineNum**  
*Find the Location of a Line of Source Code, or Set a Breakpoint There.*

**Description**

These functions locate objects containing particular lines of source code, using the information saved when the code was parsed with `keep.source = TRUE`. 
findLineNum

Usage

findLineNum(srcfile, line, nameonly = TRUE,
             envir = parent.frame(), lastenv)

setBreakpoint(srcfile, line, nameonly = TRUE,
              envir = parent.frame(), lastenv, verbose = TRUE,
              tracer, print = FALSE, clear = FALSE, ...)

Arguments

srcfile  The name of the file containing the source code.
line     The line number within the file. See Details for an alternate way to specify this.
nameonly If TRUE (the default), we require only a match to basename(srcfile), not to
          the full path.
envir    Where do we start looking for function objects?
lastenv  Where do we stop? See the Details.
verbose  Should we print information on where breakpoints were set?
tracer   An optional tracer function to pass to trace. By default, a call to browser is
          inserted.
print    The print argument to pass to trace.
clear    If TRUE, call untrace rather than trace.
...      Additional arguments to pass to trace.

Details

The findLineNum function searches through all objects in environment envir, its parent, grandpar-
ent, etc., all the way back to lastenv.

lastenv defaults to the global environment if envir is not specified, and to the root environment
emptyenv() if envir is specified. (The first default tends to be quite fast, and will usually find all
user code other than S4 methods; the second one is quite slow, as it will typically search all attached
system libraries.)

For convenience, envir may be specified indirectly: if it is not an environment, it will be replaced
with environment(envir).

setBreakpoint is a simple wrapper function for trace and untrace. It will set or clear breakpoints
at the locations found by findLineNum.

The srcfile is normally a filename entered as a character string, but it may be a "srcfile" object,
or it may include a suffix like "filename.nn", in which case the number nn will be used as a
default value for line.

As described in the description of the where argument on the man page for trace, the R package
system uses a complicated scheme that may include more than one copy of a function in a package.
The user will typically see the public one on the search path, while code in the package will see
a private one in the package NAMESPACE. If you set envir to the environment of a function
in the package, by default findLineNum will find both versions, and setBreakpoint will set the
breakpoint in both. (This can be controlled using lastenv; e.g., envir = environment(foo),
lastenv = globalenv() will find only the private copy, as the search is stopped before seeing the
public copy.)

S version 4 methods are also somewhat tricky to find. They are stored with the generic
function, which may be in the base or other package, so it is usually necessary to have
lastenv = emptyenv() in order to find them. In some cases transformations are done by R when storing them and findLineNum may not be able to find the original code. Many special cases, e.g. methods on primitive generics, are not yet supported.

Value
findLineNum returns a list of objects containing location information. A print method is defined for them.
setBreakpoint has no useful return value; it is called for the side effect of calling trace or untrace.

trace

Examples

```r
## Not run:
# Find what function was defined in the file mysource.R at line 100:
findLineNum("mysource.R#100")

# Set a breakpoint in both copies of that function, assuming one is in the
# same namespace as myfunction and the other is on the search path
setBreakpoint("mysource.R#100", envir = myfunction)

## End(Not run)
```

Description

`fix` invokes `edit` on `x` and then assigns the new (edited) version of `x` in the user’s workspace.

Usage

```r
fix(x, ...)
```

Arguments

- `x` the name of an R object, as a name or a character string.
- `...` arguments to pass to editor: see `edit`.

Details

The name supplied as `x` need not exist as an R object, in which case a function with no arguments and an empty body is supplied for editing.

Editing an R object may change it in ways other than are obvious: see the comment under `edit`. See `edit.data.frame` for changes that can occur when editing a data frame or matrix.
flush.console

See Also

edit.edit.data.frame

Examples

## Not run:
## Assume 'my.fun' is a user defined function:
fix(my.fun)
## now my.fun is changed
## Also,
fix(my.data.frame) # calls up data editor
fix(my.data.frame, factor.mode="char") # use of ...

## End(Not run)

flush.console

Flush Output to A Console

Description

This does nothing except on console-based versions of R. On the OS X and Windows GUIs, it ensures that the display of output in the console is current, even if output buffering is on.

Usage

flush.console()

format

Format Unordered and Ordered Lists

Description

Format unordered (itemize) and ordered (enumerate) lists.

Usage

formatUL(x, label = "x", offset = 0,
          width = 0.9 *getOption("width"))
formatOL(x, type = "arabic", offset = 0, start = 1,
         width = 0.9 *getOption("width"))

Arguments

x a character vector of list items.
label a character string used for labelling the items.
offset a non-negative integer giving the offset (indentation) of the list.
width a positive integer giving the target column for wrapping lines in the output.
type  a character string specifying the 'type' of the labels in the ordered list. If "arabic" (default), arabic numerals are used. For "Alph" or "alph", single upper or lower case letters are employed (in this case, the number of the last item must not exceed 26. Finally, for "Roman" or "roman", the labels are given as upper or lower case roman numerals (with the number of the last item maximally 3899). type can be given as a unique abbreviation of the above, or as one of the HTML style tokens "1" (arabic), "A"/"a" (alphabetic), or "I"/"i" (roman), respectively.

start  a positive integer specifying the starting number of the first item in an ordered list.

Value
A character vector with the formatted entries.

See Also
formatDL for formatting description lists.

Examples
## A simpler recipe.
x <- c("Mix dry ingredients thoroughly.",
   "Pour in wet ingredients.",
   "Mix for 10 minutes.",
   "Bake for one hour at 300 degrees.")## Format and output as an unordered list.
writeln(formatUL(x))## Format and output as an ordered list.
writeln(formatOL(x))## Ordered list using lower case roman numerals.
writeln(formatOL(x, type = "l"))## Ordered list using upper case letters and some offset.
writeln(formatOL(x, type = "A", offset = 5))
Details

These functions look at all loaded namespaces, whether or not they are associated with a package on the search list.

They do not search literally “anywhere”: for example, local evaluation frames and namespaces that are not loaded will not be searched.

Where functions are found as registered S3 methods, an attempt is made to find which namespace registered them. This may not be correct, especially if namespaces have been unloaded.

Value

For `getAnywhere()` an object of class "getAnywhere". This is a list with components

- `name`: the name searched for
- `objs`: a list of objects found
- `where`: a character vector explaining where the object(s) were found
- `visible`: logical: is the object visible
- `dups`: logical: is the object identical to one earlier in the list.

In computing whether objects are identical, their environments are ignored.

Normally the structure will be hidden by the `print` method. There is a `[` method to extract one or more of the objects found.

For `argsAnywhere()` one or more argument lists as returned by `args`.

See Also

`getS3method` to find the method which would be used: this might not be the one of those returned by `getAnywhere` since it might have come from a namespace which was unloaded or be registered under another name.

`get, getFromNamespace, args`

Examples

```r
getAnywhere("format.dist")
getAnywhere("simpleLoess") # not exported from stats
argsAnywhere(format.dist)
```

Description

Utility functions to access and replace the non-exported functions in a namespace, for use in developing packages with namespaces.

They should not be used in production code (except perhaps `assignInMyNamespace`, but see the ‘Note’).
Usage

getFromNamespace(x, ns, pos = -1, envir = as.environment(pos))

assignInNamespace(x, value, ns, pos = -1,
                  envir = as.environment(pos))

assignInMyNamespace(x, value)

fixInNamespace(x, ns, pos = -1, envir = as.environment(pos), ...)

Arguments

x          an object name (given as a character string).
value      an R object.
ns          a namespace, or character string giving the namespace.
pos          where to look for the object: see get.
envir      an alternative way to specify an environment to look in.
...        arguments to pass to the editor: see edit.

Details

assignInMyNamespace is intended to be called from functions within a package, and chooses the namespace as the environment of the function calling it.

The namespace can be specified in several ways. Using, for example, ns = "stats" is the most direct, but a loaded package can be specified via any of the methods used for get: ns can also be the environment printed as <namespace:foo>.

getFromNamespace is similar to (but predates) the :::: operator: it is more flexible in how the namespace is specified.

fixInNamespace invokes edit on the object named x and assigns the revised object in place of the original object. For compatibility with fix, x can be unquoted.

Value

getFromNamespace returns the object found (or gives an error).

assignInNamespace, assignInMyNamespace and fixInNamespace are invoked for their side effect of changing the object in the namespace.

Warning

assignInNamespace should not be used in final code, and will in future throw an error if called from a package. Already certain uses are disallowed.

Note

assignInNamespace, assignInMyNamespace and fixInNamespace change the copy in the namespace, but not any copies already exported from the namespace, in particular an object of that name in the package (if already attached) and any copies already imported into other namespaces. They are really intended to be used only for objects which are not exported from the namespace. They do attempt to alter a copy registered as an S3 method if one is found.

They can only be used to change the values of objects in the namespace, not to create new objects.
getParsedata

Get detailed parse information from object.

Description

If the "keep source" option is TRUE, R's parser will attach detailed information on the object it has parsed. These functions retrieve that information.

Usage

getParsedata(x, includeText = NA)
getParseText(parseData, id)

Arguments

x an expression returned from parse, or a function or other object with source reference information
includeText logical; whether to include the text of parsed items in the result
parseData a data frame returned from getParseData
id a vector of item identifiers whose text is to be retrieved

Details

In version 3.0.0, the R parser was modified to include code written by Romain Francois in his parser package. This constructs a detailed table of information about every token and higher level construct in parsed code. This table is stored in the srcfile record associated with source references in the parsed code, and retrieved by the getParseData function.

Value

For getParseData:
If parse data is not present, NULL. Otherwise a data frame is returned, containing the following columns:

line1 integer. The line number where the item starts. This is the parsed line number called "parse" in getSrcLocation, which ignores #line directives.
getParseData

col1  integer. The column number where the item starts. The first character is column 1. This corresponds to "column" in `getSrcLocation`.

line2  integer. The line number where the item ends.

col2  integer. The column number where the item ends.

id  integer. An identifier associated with this item.

parent  integer. The id of the parent of this item.

token  character. The type of the token.

terminal  logical. Whether the token is "terminal", i.e. a leaf in the parse tree.

text  character. If `includeText` is TRUE, the text of all tokens; if it is NA (the default), the text of terminal tokens. If `includeText` == FALSE, this column is not included.

The rownames of the data frame will be equal to the id values, and the data frame will have a "srcfile" attribute containing the `srcfile` record which was used. The rows will be ordered by starting position within the source file, with parent items occurring before their children.

For `getParseText`:
A character vector of the same length as id containing the associated text items. If they are not included in `parseData`, they will be retrieved from the original file.

**Note**

There are a number of differences in the results returned by `getParseData` relative to those in the original `parser` code:

- Fewer columns are kept.
- The internal token number is not returned.
- `col1` starts counting at 1, not 0.
- The id values are not attached to the elements of the parse tree, they are only retained in the table returned by `getParseData`.
- #line directives are identified, but other comment markup (e.g., roxygen comments) are not.

**Author(s)**

Duncan Murdoch

**References**

**See Also**

`parse`, `srcref`

**Examples**

```r
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}

d <- getParseData(fn)
```
gets3method

Description
Get a method for an S3 generic, possibly from a namespace or the generic’s registry.

Usage
gets3method(f, class, optional = FALSE)

Arguments
f character: name of the generic.
class character: name of the class.
optional logical: should failure to find the generic or a method be allowed?

Details
S3 methods may be hidden in namespaces, and will not then be found by get: this function can retrieve such functions, primarily for debugging purposes.

Further, S3 methods can be registered on the generic when a namespace is loaded, and the registered method will be used if none is visible (using namespace scoping rules).

It is possible that which S3 method will be used may depend on where the generic f is called from:
gets3method returns the method found if f were called from the same environment.

Value
The function found, or NULL if no function is found and optional = TRUE.

See Also
methods, get, getAnywhere

Examples
require(stats)
exists("predict.ppr") # false
gets3method("predict", "ppr")
glob2rx  

*Change Wildcard or Globbing Pattern into Regular Expression*

**Description**

Change wildcard aka globbing patterns into the corresponding regular expressions *(regexp)*.

**Usage**

glob2rx(pattern, trim.head = FALSE, trim.tail = TRUE)

**Arguments**

- **pattern**: character vector
- **trim.head**: logical specifying if leading "^.*" should be trimmed from the result.
- **trim.tail**: logical specifying if trailing " .*$" should be trimmed from the result.

**Details**

This takes a wildcard as used by most shells and returns an equivalent regular expression. ? is mapped to . (match a single character), * to .* (match any string, including an empty one), and the pattern is anchored (it must start at the beginning and end at the end). Optionally, the resulting regexp is simplified.

Note that now even ., [], and { can be used in pattern, but glob2rx() may not work correctly with arbitrary characters in pattern.

**Value**

A character vector of the same length as the input pattern where each wildcard is translated to the corresponding regular expression.

**Author(s)**

Martin Maechler, Unix/sed based version, 1991; current: 2004

**See Also**

regexp about regular expression, sub, etc about substitutions using regexps.

**Examples**

```r
stopifnot(glob2rx("abc.*") == "^abc\..",
glob2rx("a?b.*") == "^a.b\..",
glob2rx("a?b.*", trim.tail = FALSE) == "^a.b\..*$",
glob2rx(".*.doc") == "^.*\..doc$",
glob2rx(".*.doc", trim.head = TRUE) == "\..doc$",
glob2rx(".*.t") == "^.*\..t$",
glob2rx(".*.t??") == "^.*\..t..$",
glob2rx(".*[s"] == "^.*\[\""
```
**globalVariables**

*Declarations Used in Checking a Package*

**Description**

For `globalVariables`, the names supplied are of functions or other objects that should be regarded as defined globally when the check tool is applied to this package. The call to `globalVariables` will be included in the package’s source. Repeated calls in the same package accumulate the names of the global variables.

Typical examples are the fields and methods in reference classes, which appear to be global objects to `c®det®®«s` (This case is handled automatically by `setRefClass()` and friends, using the supplied field and method names.)

For `suppressf®reigncheck`, the names supplied are of variables used as .NAME in foreign function calls which should not be checked by `checkFF(registration = TRUE)`. Without this declaration, expressions other than simple character strings are assumed to evaluate to registered native symbol objects. The type of call (.Call, .External, etc.) and argument counts will be checked. With this declaration, checks on those names will usually be suppressed. (If the code uses an expression that should only be evaluated at runtime, the message can be suppressed by wrapping it in a `dontCheck` function call, or by saving it to a local variable, and suppressing messages about that variable. See the example below.)

**Usage**

```
globalVariables(names, package, add = TRUE)
suppressForeignCheck(names, package, add = TRUE)
```

**Arguments**

- `names` The character vector of object names. If omitted, the current list of global variables declared in the package will be returned, unchanged.
- `package` The relevant package, usually the character string name of the package but optionally its corresponding namespace environment.
  
  When the call to `globalVariables` or `suppressForeignCheck` comes in the package’s source file, the argument is normally omitted, as in the example below.
- `add` Should the contents of `names` be added to the current global variables or replace it?

**Details**

The lists of declared global variables and native symbol objects are stored in a metadata object in the package’s namespace, assuming the `globalVariables` or `suppressForeignCheck` call(s) occur as top-level calls in the package’s source code.

The check command, as implemented in package `tools`, queries the list before checking the R source code in the package for possible problems.

`globalVariables` was introduced in R 2.15.1 and `suppressForeignCheck` was introduced in R 3.1.0 so both should be used conditionally: see the example.
globalVariables returns the current list of declared global variables, possibly modified by this call.

suppressForeignCheck returns the current list of native symbol objects which are not to be checked.

Note

The global variables list really belongs to a restricted scope (a function or a group of method definitions, for example) rather than the package as a whole. However, implementing finer control would require changes in check and/or in codetools, so in this version the information is stored at the package level.

Author(s)

John Chambers and Duncan Murdoch

See Also
dontCheck.

Examples

### Not run:

### assume your package has some code that assigns ".obj1" and ".obj2"
### but not in a way that codetools can find.
### In the same source file (to remind you that you did it) add:
if(getRversion() \(≥ \) "2.15.1") { utils::globalVariables(c(".obj1", "obj2"))

### To suppress messages about a run-time calculated native symbol,
### save it to a local variable.

### At top level, put this:
if(getRversion() \(≥ \) "3.1.0") { utils::suppressForeignCheck("localvariable")

### Within your function, do the call like this:
localvariable \(<\) if (condition) entry1 else entry2
.Call(localvariable, 1, 2, 3)

### Alternatively, like this:
if(getRversion() \(<\) "3.1.0") dontCheck \(<\) identity
.Call(dontCheck(if (condition) entry1 else entry2), 1, 2, 3)

### HOWEVER, it is much better practice to write code
### that can be checked thoroughly, e.g.
if(condition) .Call(entry1, 1, 2, 3) else .Call(entry2, 1, 2, 3)

### End(Not run)
Return the First or Last Part of an Object

Description

Returns the first or last parts of a vector, matrix, table, data frame or function. Since head() and tail() are generic functions, they may also have been extended to other classes.

Usage

head(x, ...)
## Default S3 method:
head(x, n = 6L, ...)
## S3 method for class 'data.frame'
head(x, n = 6L, ...)
## S3 method for class 'matrix'
head(x, n = 6L, ...)
## S3 method for class 'ftable'
head(x, n = 6L, ...)
## S3 method for class 'table'
head(x, n = 6L, ...)
## S3 method for class 'function'
head(x, n = 6L, ...)

tail(x, ...)
## Default S3 method:
tail(x, n = 6L, ...)
## S3 method for class 'data.frame'
tail(x, n = 6L, ...)
## S3 method for class 'matrix'
tail(x, n = 6L, addrownums = TRUE, ...)
## S3 method for class 'ftable'
tail(x, n = 6L, addrownums = FALSE, ...)
## S3 method for class 'table'
tail(x, n = 6L, addrownums = TRUE, ...)
## S3 method for class 'function'
tail(x, n = 6L, ...)

Arguments

x an object

n a single integer. If positive, size for the resulting object: number of elements for a vector (including lists), rows for a matrix or data frame or lines for a function. If negative, all but the n last/first number of elements of x.

addrownums if there are no row names, create them from the row numbers.

... arguments to be passed to or from other methods.
Details

For matrices, 2-dim tables and data frames, head() (tail()) returns the first (last) \( n \) rows when \( n > 0 \) or all but the last (first) \( n \) rows when \( n < 0 \). head.matrix() and tail.matrix() are exported. For functions, the lines of the deparsed function are returned as character strings.

If a matrix has no row names, then tail() will add row names of the form "[n,]" to the result, so that it looks similar to the last lines of \( x \) when printed. Setting addrownms = FALSE suppresses this behaviour.

Value

An object (usually) like \( x \) but generally smaller. For ftable objects \( x \), a transformed format(\( x \)).

Author(s)

Patrick Burns, improved and corrected by R-Core. Negative argument added by Vincent Goulet.

Examples

head(letters)
head(letters, n = -6L)

head(freeny.x, n = 10L)
head(freeny.y)

tail(letters)
tail(letters, n = -6L)

tail(freeny.x)
tail(freeny.y)

tail(library)
head(stats::ftable(Titanic))
help

Arguments

**topic**

usually, a name or character string specifying the topic for which help is sought. A character string (enclosed in explicit single or double quotes) is always taken as naming a topic.

If the value of topic is a length-one character vector the topic is taken to be the value of the only element. Otherwise topic must be a name or a reserved word (if syntactically valid) or character string.

See ‘Details’ for what happens if this is omitted.

**package**

a name or character vector giving the packages to look into for documentation, or NULL. By default, all packages whose namespaces are loaded are used. To avoid a name being deparsed use e.g. (pkg_ref) (see the examples).

**lib.loc**

a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries. This is not used for HTML help (see ‘Details’).

**verbose**

logical; if TRUE, the file name is reported.

**try.all.packages**

logical; see Note.

**help_type**

character string: the type of help required. Possible values are "text", "html" and "pdf". Case is ignored, and partial matching is allowed.

Details

The following types of help are available:

- Plain text help
- HTML help pages with hyperlinks to other topics, shown in a browser by browseURL. (Where possible an existing browser window is re-used: the OS X GUI uses its own browser window.) If for some reason HTML help is unavailable (see startDynamicHelp), plain text help will be used instead.
- For help only, typeset as PDF – see the section on ‘Offline help’.

The ‘factory-fresh’ default is text help except from the OS X GUI, which uses HTML help displayed in its own browser window.

The rendering of text help will use directional quotes in suitable locales (UTF-8 and single-byte Windows locales): sometimes the fonts used do not support these quotes so this can be turned off by setting options(useFancyQuotes = FALSE).

**topic** is not optional: if it is omitted R will give

- If a package is specified, (text or, in interactive use only, HTML) information on the package, including hints/links to suitable help topics.
- If lib.loc only is specified, a (text) list of available packages.
- Help on help itself if none of the first three arguments is specified.

Some topics need to be quoted (by backticks) or given as a character string. These include those which cannot syntactically appear on their own such as unary and binary operators, function and control-flow reserved words (including if, else for, in, repeat, while, break and next). The other reserved words can be used as if they were names, for example TRUE, NA and Inf.

If multiple help files matching topic are found, in interactive use a menu is presented for the user to choose one: in batch use the first on the search path is used. (For HTML help the menu will be
an HTML page, otherwise a graphical menu if possible if `getOption("menu.graphics")` is true, the default.

Note that HTML help does not make use of lib.loc: it will always look first in the loaded packages and then along `libPaths()`.

**Offline help**

Typeset documentation is produced by running the LaTeX version of the help page through `pdflatex`: this will produce a PDF file.

The appearance of the output can be customized through a file ‘Rhelp.cfg’ somewhere in your LaTeX search path: this will be input as a LaTeX style file after `Rd.sty`. Some environment variables are consulted, notably `R_PAPERSIZE` (via `getOption("papersize")`) and `R_RD4PDF` (see ‘Making manuals’ in the ‘R Installation and Administration Manual’).

If there is a function `offline.help.helper` in the workspace or further down the search path it is used to do the typesetting, otherwise the function of that name in the `utils` namespace (to which the first paragraph applies). It should accept at least two arguments, the name of the LaTeX file to be typeset and the type (which is nowadays ignored). It accepts a third argument, `texinputs`, which will give the graphics path when the help document contains figures, and will otherwise not be supplied.

**Note**

Unless `lib.loc` is specified explicitly, the loaded packages are searched before those in the specified libraries. This ensures that if a library is loaded from a library not in the known library trees, then the help from the loaded library is used. If `lib.loc` is specified explicitly, the loaded packages are not searched.

If this search fails and argument `try.all.packages` is `TRUE` and neither `lib.loc` is specified, then all the packages in the known library trees are searched for help on topic and a list of (any) packages where help may be found is displayed (with hyperlinks for `help_type = "html"`). **NB:** searching all packages can be slow, especially the first time (caching of files by the OS can expedite subsequent searches dramatically).

**References**

**See Also**

`?` for shortcuts to help topics.

`help.search()` or `??` for finding help pages on a vague topic; `help.start()` which opens the HTML version of the R help pages; `library()` for listing available packages and the help objects they contain; `data()` for listing available data sets; `methods()`.

Use `prompt()` to get a prototype for writing help pages of your own package.

**Examples**

```
help()
help(help)  # the same

help(lapply)
```
Help

Help request

Send a Post to R-help

Description

Prompts the user to check they have done all that is expected of them before sending a post to the R-help mailing list, provides a template for the post with session information included and optionally sends the email (on Unix systems).

Usage

help.request(subject = "", address = "r-help@R-project.org", file = "R.help.request", ...)

Arguments

subject subject of the email. Please do not use single quotes (') in the subject! Post separate help requests for multiple queries.
address recipient's email address.
file filename to use (if needed) for setting up the email.
... additional named arguments such as method and ccaddress to pass to create.post.

Details

This function is not intended to replace the posting guide. Please read the guide before posting to R-help or using this function (see http://www.r-project.org/posting-guide.html).

The help.request function:

• asks whether the user has consulted relevant resources, stopping and opening the relevant URL if a negative response is given.
help.search

- checks whether the current version of R is being used and whether the add-on packages are up-to-date, giving the option of updating where necessary.
- asks whether the user has prepared appropriate (minimal, reproducible, self-contained, commented) example code ready to paste into the post.

Once this checklist has been completed a template post is prepared including current session information, and passed to create.post.

Value

Nothing useful.

Author(s)

Heather Turner, based on the then current code and help page of bug.report().

See Also

The posting guide (http://www.r-project.org/posting-guide.html), also sessionInfo() from which you may add to the help request.

create.post.

help.search Search the Help System

Description

Allows for searching the help system for documentation matching a given character string in the (file) name, alias, title, concept or keyword entries (or any combination thereof), using either fuzzy matching or regular expression matching. Names and titles of the matched help entries are displayed nicely formatted.

Vignette names, titles and keywords and demo names and titles may also be searched.

Usage

help.search(pattern, fields = c("alias", "concept", "title"),
           apropos, keyword, whatis, ignore.case = TRUE,
           package = NULL, lib.loc = NULL,
           help.db =getOption("help.db"),
           verbose =getOption("verbose"),
           rebuild =FALSE, agrep = NULL, use_UTF8 = FALSE,
           types =getOption("help.search.types"))

??pattern
field??pattern
help.search

Arguments

- **pattern**: a character string to be matched in the specified fields. If this is given, the arguments `apropos`, `keyword`, and `whatis` are ignored.
- **fields**: a character vector specifying the fields of the help database to be searched. The entries must be abbreviations of "name", "title", "alias", "concept", and "keyword", corresponding to the help page's (file) name, its title, the topics and concepts it provides documentation for, and the keywords it can be classified to. See below for how vignettes and demos are searched.
- **apropos**: a character string to be matched in the help page topics and title.
- **keyword**: a character string to be matched in the help page 'keywords'. ‘Keywords’ are really categories: the standard categories are listed in file `R.home("doc")/KEYWORDS` (see also the example) and some package writers have defined their own. If `keyword` is specified, `agrep` defaults to `FALSE`.
- **whatis**: a character string to be matched in the help page topics.
- **ignore.case**: a logical. If `TRUE`, case is ignored during matching; if `FALSE`, pattern matching is case sensitive.
- **package**: a character vector with the names of packages to search through, or `NULL` in which case all available packages in the library trees specified by `lib.loc` are searched.
- **lib.loc**: a character vector describing the location of R library trees to search through, or `NULL`. The default value of `NULL` corresponds to all libraries currently known.
- **help.db**: a character string giving the file path to a previously built and saved help database, or `NULL`.
- **verbose**: logical; if `TRUE`, the search process is traced. Integer values are also accepted, with `TRUE` being equivalent to 2, and 1 being less verbose. On Windows a progress bar is shown during rebuilding, and on Unix a heartbeat is shown for `verbose = 1` and a package-by-package list for `verbose >= 2`.
- **rebuild**: a logical indicating whether the help database should be rebuilt. This will be done automatically if `lib.loc` or the search path is changed, or if package is used and a value is not found.
- **agrep**: if `NULL` (the default unless `keyword` is used) and the character string to be matched consists of alphanumeric characters, whitespace or a dash only, approximate (fuzzy) matching via `agrep` is used unless the string has fewer than 5 characters; otherwise, it is taken to contain a regular expression to be matched via `grep`. If `FALSE`, approximate matching is not used. Otherwise, one can give a numeric or a list specifying the maximal distance for the approximate match, see argument `max.distance` in the documentation for `agrep`.
- **use_UTF8**: logical: should be results be given in UTF-8 encoding? Also changes the meaning of regexps in `agrep` to be Perl regexps.
- **types**: a character vector listing the types of documentation to search. The entries must be abbreviations of "vignette" "help" or "demo". Results will be presented in the order specified.
- **field**: a single value of `fields` to search.

Details

Upon installation of a package, a pre-built `help.search` index is serialized as `hsearch_rds` in the ‘Meta’ directory (provided the package has any help pages). Vignettes are also indexed in the ‘Meta/vignette.rds’ file. These files are used to create the help search database.
The arguments `apropos` and `what` play a role similar to the Unix commands with the same names. Searching with `agrep = FALSE` will be several times faster than the default (once the database is built). However, approximate searches should be fast enough (around a second with 5000 packages installed).

If possible, the help database is saved in memory for use by subsequent calls in the session.

Note that currently the aliases in the matching help files are not displayed.

As with ?, in ?? the pattern may be prefixed with a package name followed by :: or ::: to limit the search to that package.

Vignettes are searched as follows. The "name" and "alias" are both the base of the vignette filename, and the "concept" entries are taken from the `|vignetteKeywords` entries. Vignettes are not classified using the help system "keyword" classifications. Demos are handled similarly to vignettes, without the "concept" search.

**Value**

The results are returned in a list object of class "hsearch", which has a print method for nicely formatting the results of the query. This mechanism is experimental, and may change in future versions of R.

In R.app on OS X, this will show up a browser with selectable items. On exiting this browser, the help pages for the selected items will be shown in separate help windows.

The internal format of the class is undocumented and subject to change.

**See Also**

`help`; `help.start` for starting the hypertext (currently HTML) version of R's online documentation, which offers a similar search mechanism.

`RSiteSearch` to access an on-line search of R resources.

`apropos` uses regexps and has nice examples.

**Examples**

```r
help.search("linear models")  # In case you forgot how to fit linear models
help.search("non-existent topic")

??utils::help  # All the topics matching "help" in the utils package

help.search("print")  # All help pages with topics or title matching 'print'
help.search(apropos = "print")  # The same
help.search(keyword = "hplot")  # All help pages documenting high-level plots.
file.show(file.path(R.home("doc"), "KEYWORDS"))  # show all keywords
```

```r
## Help pages with documented topics starting with 'try'.
help.search("\btry\", fields = "alias")
```
help.start

Hypertext Documentation

Description

Start the hypertext (currently HTML) version of R’s online documentation.

Usage

help.start(update = FALSE, gui = "irrelevant",
            browser =getOption("browser"), remote = NULL)

Arguments

update logical: should this attempt to update the package index to reflect the currently available packages. (Not attempted if remote is non-NULL.)
gui just for compatibility with S-PLUS.
browser the name of the program to be used as hypertext browser. It should be in the PATH, or a full path specified. Alternatively, it can be an R function which will be called with a URL as its only argument. This option is normally unset on Windows, when the file-association mechanism will be used.
remote A character string giving a valid URL for the ‘R_HOME’ directory on a remote location.

Details

Unless remote is specified this requires the HTTP server to be available (it will be started if possible: see startDynamicHelp).

One of the links on the index page is the HTML package index, ‘R.home("docs")/html/packages.html’, which can be remade by make.packages.html(). For local operation, the HTTP server will remake a temporary version of this list when the link is first clicked, and each time thereafter check if updating is needed (if .libPaths has changed or any of the directories has been changed). This can be slow, and using update = TRUE will ensure that the packages list is updated before launching the index page.

Argument remote can be used to point to HTML help published by another R installation: it will typically only show packages from the main library of that installation.

See Also

help() for on- and off-line help in other formats.
browseURL for how the help file is displayed.
RSiteSearch to access an on-line search of R resources.

Examples

help.start()
## Not run:
## the 'remote' arg can be tested by
help.start(remote = paste0("file://", R.home()))

## End(Not run)
**DESCRIPTION**

Utility for installing add-on packages.

**USAGE**

```
R CMD INSTALL [options] [-l lib] pkgs
```

**ARGUMENTS**

- `pkgs`  a space-separated list with the path names of the packages to be installed. See 'Details'.
- `lib`    the path name of the R library tree to install to. Also accepted in the form `--library=lib`. Paths including spaces should be quoted, using the conventions for the shell in use.
- `options` a space-separated list of options through which in particular the process for building the help files can be controlled. Use `R CMD INSTALL --help` for the full current list of options.

**DETAILS**

This will stop at the first error, so if you want all the `pkgs` to be tried, call this via a shell loop.

If used as `R CMD INSTALL pkgs` without explicitly specifying `lib`, packages are installed into the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To install into the library tree `lib`, use `R CMD INSTALL -l lib pkgs`. This prepends `lib` to the library path for duration of the install, so required packages in the installation directory will be found (and used in preference to those in other libraries).

Both `lib` and the elements of `pkgs` may be absolute or relative path names of directories. `pkgs` may also contain names of package archive files: these are then extracted to a temporary directory. These are tarballs containing a single directory, optionally compressed by gzip, bzip2, xz or compress. Finally, binary package archive files (as created by `R CMD INSTALL --build`) can be supplied.

Tarballs are by default unpackaged by the internal `untar` function: if needed an external `tar` command can be specified by the environment variable `R_INSTALL_TAR`: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting `R_INSTALL_TAR` to `tar.exe` has been needed to overcome permissions issues on some Windows systems.)

The package sources can be cleaned up prior to installation by `--preclean` or after by `--clean`: cleaning is essential if the sources are to be used with more than one architecture or platform.

Some package sources contain a `configure` script that can be passed arguments or variables via the option `--configure-args` and `--configure-vars`, respectively, if necessary. The latter is useful in particular if libraries or header files needed for the package are in non-system directories. In this case, one can use the configure variables `LIBS` and `CPPFLAGS` to specify these locations (and set these via `--configure-vars`), see section “Configuration variables” in “R Installation and Administration” for more information. (If these are used more than once on the command line they are concatenated.) The configure mechanism can be bypassed using the option `--no-configure`. 
If the attempt to install the package fails, leftovers are removed. If the package was already installed, the old version is restored. This happens either if a command encounters an error or if the install is interrupted from the keyboard: after cleaning up the script terminates.

For details of the locking which is done, see the section ‘Locking’ in the help for install.packages.

Option ‘--build’ can be used to tar up the installed package for distribution as a binary package (as used on OS X). This is done by utils::tar unless environment variable R_INSTALL_TAR is set. By default a package is installed with static HTML help pages if and only if R was: use options ‘--html’ and ‘--no-html’ to override this.

Packages are not by default installed keeping the source formatting (see the keep.source argument to source): this can be enabled by the option ‘--with-keep.source’ or by setting environment variable R_KEEP_PKG_SOURCE to yes.

Use `R CMD INSTALL --help` for concise usage information, including all the available options.

Sub-architectures

An R installation can support more than one sub-architecture: currently this is most commonly used for 32- and 64-bit builds on Windows.

For such installations, the default behaviour is to try to install source packages for all installed sub-architectures unless the package has a configure script or a 'src/Makefile' (or 'src/Makefile.win' on Windows), when only compiled code for the sub-architecture running `R CMD INSTALL` is installed.

To install a source package with compiled code only for the sub-architecture used by `R CMD INSTALL`, use ‘--no-multiarch’. To install just the compiled code for another sub-architecture, use ‘--libs-only’.

There are two ways to install for all available sub-architectures. If the configure script is known to work for both Windows architectures, use flag ‘--force-biarch’ (and packages can specify this via a 'Biarch' field in their DESCRIPTION files). Second, a single tarball can be installed with

```
R CMD INSTALL --merge-multiarch mypkg_version.tar.gz
```

Note

The options do not have to precede ‘pkgs’ on the command line, although it will be more legible if they do. All the options are processed before any packages, and where options have conflicting effects the last one will win.

Some parts of the operation of INSTALL depend on the R temporary directory (see `tempdir`, usually under ‘/tmp’) having both write and execution access to the account running R. This is usually the case, but if ‘/tmp’ has been mounted as noexec, environment variable TMPDIR may need to be set to a directory from which execution is allowed.

See Also

`REMOVE`, `libPaths` for information on using several library trees; `install.packages` for R-level installation of packages; `update.packages` for automatic update of packages using the Internet or a local repository.

install.packages  

Install Packages from Repositories or Local Files

Description

Download and install packages from CRAN-like repositories or from local files.

Usage

install.packages(pkgs, lib, repos = getOption("repos"),
                 contriburl = contrib.url(repos, type),
                 method, available = NULL, destdir = NULL,
                 dependencies = NA, type = getOption("pkgType"),
                 configure.args = getOption("configure.args"),
                 configure.vars = getOption("configure.vars"),
                 clean = FALSE, Ncpus = getOption("Ncpus", 1L),
                 verbose = getOption("verbose"),
                 libs_only = FALSE, INSTALL_opts, quiet = FALSE,
                 keep_outputs = FALSE, ...)

Arguments

- **pkgs**
  - character vector of the names of packages whose current versions should be downloaded from the repositories.
  - If `repos = NULL`, a character vector of file paths. These can be source directories or archives or binary package archive files (as created by `CMD build --binary`). (http:// and file:// URLs are also accepted and the files will be downloaded and installed from local copies.) On a CRAN build of R for OS X these can be `.tgz` files containing binary package archives. Tilde-expansion will be done on file paths.
  - If this is missing or a zero-length character vector, a listbox of available packages is presented where possible in an interactive R session.

- **lib**
  - character vector giving the library directories where to install the packages. Recycled as needed. If missing, defaults to the first element of `.libPaths()`.

- **repos**
  - character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as "http://cran.us.r-project.org". For more details on supported URL schemes see `url1`.
  - Can be `NULL` to install from local files, directories or URLs: this will be inferred by extension from pkgs if of length one.

- **contriburl**
  - URL(s) of the contrib sections of the repositories. Use this argument if your repository mirror is incomplete, e.g., because you burned only the `contrib` section on a CD, or only have binary packages. Overrides argument `repos`. Incompatible with `type = "both"`. 

- **method**
  - download method, see `download.file`. Unused if a non-NULL available is supplied.

- **available**
  - a matrix as returned by `available.packages` listing packages available at the repositories, or `NULL` when the function makes an internal call to `available.packages`. Incompatible with `type = "both"`. 

**install.packages**

**destdir**
- directory where downloaded packages are stored. If it is NULL (the default) a subdirectory of the session temporary directory will be used (and the files will be deleted at the end of the session).

**dependencies**
- logical indicating whether to also install uninstalled packages which these packages depend on/link to/import/suggest (and so on recursively). Not used if `repos = NULL`. Can also be a character vector, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Only supported if `lib` is of length one (or missing), so it is unambiguous where to install the dependent packages. If this is not the case it is ignored, with a warning.

The default, NA, means c("Depends", "Imports", "LinkingTo"). TRUE means to use c("Depends", "Imports", "LinkingTo", "Suggests") for `pkgs` and c("Depends", "Imports", "LinkingTo") for added dependencies: this installs all the packages needed to run `pkgs`, their examples, tests and vignettes (if the package author specified them correctly).

In all of these, "LinkingTo" is omitted for binary packages.

**type**
- character, indicating the type of package to download and install.

Possible values are (currently) "source", "mac.binary", "mac.binary.mavericks" and "win.binary": the binary types can be listed and downloaded but not installed on other platforms.

The default is the appropriate binary type on Windows and on the CRAN binary OS X distributions, otherwise "source". Where there is binary type, it can also be selected as "binary".

For the platforms where binary packages are the default, an alternative is "both" which means 'try binary if available and current, otherwise try source'. (This will only prefer the binary version of a package if its version number is no older than the source version. In interactive use it will ask before attempting to install source packages which may contain compiled code.)

**configure.args**
- (Used only for source installs.) A character vector or a named list. If a character vector with no names is supplied, the elements are concatenated into a single string (separated by a space) and used as the value for the '--configure-args' flag in the call to `R CMD INSTALL`. If the character vector has names these are assumed to identify values for '--configure-args' for individual packages. This allows one to specify settings for an entire collection of packages which will be used if any of those packages are to be installed. (These settings can therefore be re-used and act as default settings.)

A named list can be used also to the same effect, and that allows multi-element character strings for each package which are concatenated to a single string to be used as the value for '--configure-args'.

**configure.vars**
- (Used only for source installs.) Analogous to `configure.args` for flag '--configure-vars', which is used to set environment variables for the configure run.

**clean**
- a logical value indicating whether to add the '--clean' flag to the call to `R CMD INSTALL`. This is sometimes used to perform additional operations at the end of the package installation in addition to removing intermediate files.

**Ncpus**
- the number of parallel processes to use for a parallel install of more than one source package. Values greater than one are supported if the make command
specified by `Sys.getenv("MAKE", "make")` accepts argument `-k -j Nc-
pus.

`verbose` a logical indicating if some "progress report" should be given.

`libs_only` a logical value: should the `--libs-only` option be used to install only additional sub-architectures for source installs? (See also `INSTALL_opts`.) This can also be used on Windows to install just the DLL(s) from a binary package, e.g. to add 64-bit DLLs to a 32-bit install.

`INSTALL_opts` an optional character vector of additional option(s) to be passed to `R CMD INSTALL` for a source package install. E.g., `c("--html", "--no-multiarch")`. Can also be a named list of character vectors to be used as additional options, with names the respective package names.

`quiet` logical: if true, reduce the amount of output.

`keep_outputs` a logical: if true, keep the outputs from installing source packages in the current working directory, with the names of the output files the package names with `.out` appended. Alternatively, a character string giving the directory in which to save the outputs. Ignored when installing from local files.

... Arguments to be passed to `download.file` or to the functions for binary installs on OS X and Windows (which accept an argument "lock": see the section on 'Locking').

**Details**

R packages are primarily distributed as *source* packages, but *binary* packages (a packaging up of the installed package) are also supported, and the type most commonly used on Windows and by the CRAN distributions for OS X. This function can install either type where supported, either by downloading a file from a repository or from a local file. The default type is given by `getOption("pkgType")`: this defaults to "source" apart from under Windows or a CRAN binary distribution for OS X.

This is the main function to install packages. It takes a vector of names and a destination library, downloads the packages from the repositories and installs them. (If the library is omitted it defaults to the first directory in `.libPaths()`, with a message if there is more than one.) If a library is omitted or is of length one and is not a (group) writable directory, in interactive use the code offers to create a personal library tree (the first element of `Sys.getenv("R_LIBS_USER")`) and install there.

For source packages from a repository an attempt is made to install the packages in an order that respects their dependencies. This does assume that all the entries in `lib` are on the default library path for installs (set by `R_LIBS`).

You are advised to run `update.packages` before `install.packages` to ensure that any already installed dependencies have their latest versions.

For binary installs, the function also checks for the availability of a source package on the same repository, and reports if the source package has a later version, or is available but no binary version is. This check can be suppressed by

```r
options(install.packages.check.source = "no")
```

and should be if there is a partial repository containing only binary files.

**Value**

Invisible NULL.
install.packages

1803

Locking

There are various options for locking: these differ between source and binary installs.

By default for a source install, the library directory is ‘locked’ by creating a directory ‘@@LOCK’ within it. This has two purposes: it prevents any other process installing into that library concurrently, and is used to store any previous version of the package to restore on error. A finer-grained locking is provided by the option ‘--pkglock’ which creates a separate lock for each package: this allows enough freedom for parallel installation. Per-package locking is the default when installing a single package, and for multiple packages when Ncpus > 1L. Finally locking (and restoration on error) can be suppressed by ‘--no-lock’.

For an OS X or Windows binary install, no locking is done by default. Setting argument lock to TRUE (it defaults to the value ofgetOption("install.lock", FALSE)) will use per-directory locking as described for source installs: if the value is "pkglock" per-package locking will be used.

If package locking is used on Windows with libs_only = TRUE and the installation fails, the package will be restored to its previous state.

Note that it is possible for the package installation to fail so badly that the lock directory is not removed: this inhibits any further installs to the library directory (or for --pkglock, of the package) until the lock directory is removed manually.

Parallel installs

Parallel installs are attempted if pkgs has length greater than one and Ncpus > 1. It makes use of a parallel make, so the make specified (default make) when R was built must be capable of supporting make -j n: GNU make, dmake and pmake do, but Solaris make and older FreeBSD make do not: if necessary environment variable MAKE can be set for the current session to select a suitable make.

install.packages needs to be able to compute all the dependencies of pkgs from available, including if one element of pkgs depends indirectly on another. This means that if for example you are installing CRAN packages which depend on Bioconductor packages which in turn depend on CRAN packages, available needs to cover both CRAN and Bioconductor packages.

Note

Some binary distributions of R have INSTALL in a separate bundle, e.g. an R-devel RPM. install.packages will give an error if called with type = "source" on such a system.

Some binary Linux distributions of R can be installed on a machine without the tools needed to install packages: a possible remedy is to do a complete install of R which should bring in all those tools as dependencies.

See download.file for how to handle proxies and other options to monitor file transfers.

INSTALL, REMOVE, remove.packages, library, .packages, read.dcf

The ‘R Installation and Administration’ manual for how to set up a repository.

Examples

## Not run:
## A Linux example for Fedora's layout of udunits2 headers.
install.packages(c("ncdf4", "RNNetCDF"),

...
configure.args = c(RNetCDF = "--with-netcdf-include=/usr/include/udunits2")

## End(Not run)

---

### Description

Find (or retrieve) details of all packages installed in the specified libraries.

### Usage

```r
installed.packages(lib.loc = NULL, priority = NULL,
                    noCache = FALSE, fields = NULL,
                    subarch = .Platform$file_arch)
```

### Arguments

- `lib.loc` character vector describing the location of R library trees to search through, or NULL for all known trees (see `.libPaths`).
- `priority` character vector or NULL (default). If non-null, used to select packages; "high" is equivalent to `c("base", "recommended")`. To select all packages without an assigned priority use `priority = "NA"`. 
- `noCache` Do not use cached information, nor cache it. 
- `fields` a character vector giving the fields to extract from each package’s DESCRIPTION file in addition to the default ones, or NULL (default). Unavailable fields result in NA values. 
- `subarch` character string or NULL. If non-null and non-empty, used to select packages which are installed for that sub-architecture.

### Details

`installed.packages` scans the ‘DESCRIPTION’ files of each package found along `lib.loc` and returns a matrix of package names, library paths and version numbers.

The information found is cached (by library) for the R session and specified `fields` argument, and updated only if the top-level library directory has been altered, for example by installing or removing a package. If the cached information becomes confused, it can be refreshed by running `install.packages(noCache = TRUE)`.

### Value

A matrix with one row per package, row names the package names and column names (currently) "Package", "LibPath", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS_type", "License" and "Built" (the R version the package was built under). Additional columns can be specified using the `fields` argument.
Note

This can be slow when thousands of packages are installed, so do not use this to find out if a named package is installed (use `system.file` or `find.package`) nor to find out if a package is usable (call `require` and check the return value) nor to find details of a small number of packages (use `packageDescription`). It needs to read several files per installed package, which will be slow on Windows and on some network-mounted file systems.

See Also

`update.packages`, `install.packages`, `INSTALL`, `REMOVE`.

Examples

```r
## confine search to .Library for speed
str(ip <- installed.packages(.Library, priority = "high"))
ip[, c(1,3:5)]
plc <- installed.packages(.Library, priority = "high", fields = "License")
## what licenses are there:
table(plc[, "License"])
```

### Description

Front-end for creating executable programs.

### Usage

```r
R CMD LINK [options] linkcmd
```

### Arguments

- `linkcmd` a list of commands to link together suitable object files (include library objects) to create the executable program.
- `options` further options to control the linking, or for obtaining information about usage and version.

### Details

The linker front-end is useful in particular when linking against the R shared or static library: see the examples.

The actual linking command is constructed by the version of `libtool` installed at `R_HOME/bin`.

`R CMD LINK --help` gives usage information.

### Note

Some binary distributions of R have LINK in a separate bundle, e.g. an R-devel RPM.

This is not available on Windows.
localeToCharset

Select a Suitable Encoding Name from a Locale Name

Description

This function aims to find a suitable coding for the locale named, by default the current locale, and if it is a UTF-8 locale a suitable single-byte encoding.

Usage

localeToCharset(locale = Sys.getlocale("LC_CTYPE"))

Arguments

locale character string naming a locale.

Details

The operation differs by OS. Locale names are normally like es_mX.iso88591. If final component indicates an encoding and it is not utf8 we just need to look up the equivalent encoding name. Otherwise, the language (here es) is used to choose a primary or fallback encoding.

In the C locale the answer will be "ASCII".

Value

A character vector naming an encoding and possibly a fallback single-encoding, NA if unknown.

Note

The encoding names are those used by libiconv, and ought also to work with glibc but maybe not with commercial Unixen.
`ls.str` and `lsf.str` are variations of `ls` applying `str()` to each matched name: see section Value.

Usage

```r
ls.str(pos = -1, name, envir, all.names = FALSE,
        pattern, mode = "any")
```

```r
lsf.str(pos = -1, envir, ...)
```

### S3 method for class 'ls_str'

```r
print(x, max.level = 1, give.attr = FALSE, 
       digits = max(1, getOption("str")$digits))
```

Arguments

- `pos` integer indicating search path position, or -1 for the current environment.
- `name` optional name indicating search path position, see `ls`.
- `envir` environment to use, see `ls`.
- `all.names` logical indicating if names which begin with a . are omitted; see `ls`.
- `pattern` a regular expression passed to `ls`. Only names matching `pattern` are considered.
- `max.level` maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default 1: Display only the first nested level.
- `give.attr` logical; if TRUE (default), show attributes as sub structures.
- `mode` character specifying the mode of objects to consider. Passed to `exists` and `get`.
- `x` an object of class "ls_str".
- `...` further arguments to pass. `lsf.str` passes them to `ls.str` which passes them on to `ls`. The (non-exported) print method `print.ls_str` passes them to `str`.
- `digits` the number of significant digits to use for printing.

Value

`ls.str` and `lsf.str` return an object of class "ls_str", basically the character vector of matching names (functions only for `lsf.str`), similarly to `ls`, with a print method that calls `str()` on each object.
Description

Show the name and email address of the maintainer of a package.

Usage

maintainer(pkg)

Arguments

pkg

Character string. The name of a single package.

Details

Accesses the package description to return the name and email address of the maintainer.

Questions about contributed packages should often be addressed to the package maintainer; questions about base packages should usually be addressed to the R-help or R-devel mailing lists. Bug reports should be submitted using the bug.report function.
Value

A character string giving the name and email address of the maintainer of the package, or NA if no such package is installed.

Author(s)

David Scott <d.scott@auckland.ac.nz> from code on R-help originally due to Charlie Sharpsteen <source@sharpsteen.net>; multiple corrections by R-core.

make.packages.html  Update HTML Package List

Description

Re-create the HTML list of packages.

Usage

make.packages.html(lib.loc = .libPaths(), temp = FALSE, verbose = TRUE, docdir = R.home("doc"))

Arguments

lib.loc character vector. List of libraries to be included.

temp logical: should the package indices be created in a temporary location for use by the HTTP server?

verbose logical. If true, print out a message.

docdir If temp is false, directory in whose ‘html’ directory the ‘packages.html’ file is to be created/updated.

Details

This creates the ‘packages.html’ file, either a temporary copy for use by help.start, or the copy in ‘R.home("doc")/html’ (for which you will need write permission).

It can be very slow, as all the package ‘DESCRIPTION’ files in all the library trees are read.

For temp = TRUE there is some caching of information, so the file will only be re-created if lib.loc or any of the directories it lists have been changed.
**Value**

Invisible logical, with FALSE indicating a failure to create the file, probably due to lack of suitable permissions.

**See Also**

help.start

**Examples**

```r
## Not run:
make.packages.html()
# this can be slow for large numbers of installed packages.

## End(Not run)
```

### make.socket

**Create a Socket Connection**

**Description**

With `server = FALSE` attempts to open a client socket to the specified port and host. With `server = TRUE` the R process listens on the specified port for a connection and then returns a server socket. It is a good idea to use `on.exit` to ensure that a socket is closed, as you only get 64 of them.

**Usage**

`make.socket(host = "localhost", port, fail = TRUE, server = FALSE)`

**Arguments**

- **host**: name of remote host
- **port**: port to connect to/listen on
- **fail**: failure to connect is an error?
- **server**: a server socket?

**Value**

An object of class "socket", a list with components:

- **socket**: socket number. This is for internal use. On a Unix-alike it is a file descriptor.
- **port**: port number of the connection.
- **host**: name of remote computer.

**Warning**

I don’t know if the connecting host name returned when `server = TRUE` can be trusted. I suspect not.
memory.size

Author(s)

Thomas Lumley

References

Adapted from Luke Tierney’s code for XLISP-Stat, in turn based on code from Robbins and Robbins “Practical UNIX Programming”.

See Also

close.socket, read.socket

Examples

daytime <- function(host = "localhost")(    a <- make.socket(host, 13)    on.exit(close.socket(a))    read.socket(a)  )  ## Official time (UTC) from US Naval Observatory  ## Not run: daytime("tick.usno.navy.mil")

memory.size  Report on Memory Allocation

Description

memory.size and memory.limit are used to manage the total memory allocation on Windows. On other platforms these are stubs which report infinity with a warning.

Usage

memory.size(max = FALSE)

memory.limit(size = NA)

Arguments

max  logical. If true the maximum amount of memory obtained from the OS is reported, otherwise the amount currently in use.

size  numeric. If NA report the memory size, otherwise request a new limit, in Mb.

Details

To restrict memory usage on a Unix-alike use the facilities of the shell used to launch R, e.g. limit or ulimit.

Value

Size in bytes: always Inf.
menu

menu Interaction Function

Description

menu presents the user with a menu of choices labelled from 1 to the number of choices. To exit without choosing an item one can select ‘0’.

Usage

menu(choices, graphics = FALSE, title = NULL)

Arguments

choices a character vector of choices
graphics a logical indicating whether a graphics menu should be used if available.
title a character string to be used as the title of the menu. NULL is also accepted.

Details

If graphics = TRUE and a windowing system is available (Windows, OS X or X11 via Tcl/Tk) a listbox widget is used, otherwise a text menu. It is an error to use menu in a non-interactive session.

Ten or fewer items will be displayed in a single column, more in multiple columns if possible within the current display width.

No title is displayed if title is NULL or "".

Value

The number corresponding to the selected item, or 0 if no choice was made.

References

See Also

select.list, which is used to implement the graphical menu, and allows multiple selections.

Examples

```r
## Not run:
switch(menu(c("List letters", "List LETTERS")) + 1,
       cat("Nothing done\n"), letters, LETTERS)
## End(Not run)
```
List Methods for S3 Generic Functions or Classes

Description

List all available methods for an S3 generic function, or all methods for a class.

Usage

methods(generic.function, class)

Arguments

generic.function
  a generic function, or a character string naming a generic function.

class
  a symbol or character string naming a class: only used if generic.function is not supplied.

Details

Function methods can be used to find out about the methods for a particular generic function or class. The functions listed are those which are named like methods and may not actually be methods (known exceptions are discarded in the code). Note that the listed methods may not be user-visible objects, but often help will be available for them.

If class is used, we check that a matching generic can be found for each user-visible object named. If generic.function is given, there is a warning if it appears not to be a generic function. (The check for being generic used can be fooled.)

Value

An object of class "MethodsFunction", a character vector of function names with an "info" attribute. There is a print method which marks with an asterisk any methods which are not visible: such functions can be examined by getS3method or getAnywhere.

The "info" attribute is a data frame, currently with a logical column, visible and a factor column from (indicating where the methods were found).

Note

This scheme is called S3 (S version 3). For new projects, it is recommended to use the more flexible and robust S4 scheme provided in the methods package. Functions can have both S3 and S4 methods, and function showMethods will list the S4 methods (possibly none).

The original methods function was written by Martin Maechler.

References

See Also
S3Methods, class, getS3method.
For S4, showMethods, Methods.

Examples

require(stats)
methods(summary)
methods(class = "aov")
methods("[[")  # uses C-internal dispatching
methods("$")
methods("\$<-")  # replacement function
methods("\*")  # binary operator
methods("Math")  # group generic
require(graphics)
methods("axis")  # looks like it has methods, but not generic
## Not run:
methods(print)  # over 100

## End(Not run)
## --> help(showMethods) for related examples

mirrorAdmin
Managing Repository Mirrors

Description
Functions helping to maintain CRAN, some of them may also be useful for administrators of other repository networks.

Usage

mirror2html(mirrors = NULL, file = "mirrors.html",
head = "mirrors-head.html", foot = "mirrors-foot.html")
checkCRAN(method)

Arguments

mirrors A data frame, by default the CRAN list of mirrors is used.
file A connection or a character string.
head Name of optional header file.
foot Name of optional footer file.
method Download method, see download.file.

Details
mirror2html creates the HTML file for the CRAN list of mirrors and invisibly returns the HTML text.
checkCRAN performs a sanity checks on all CRAN mirrors.
**modifyList**

*Recursively Modify Elements of a List*

**Description**

Modifies a possibly nested list recursively by changing a subset of elements at each level to match a second list.

**Usage**

```r
modifyList(x, val, keep.null = FALSE)
```

**Arguments**

- `x` A named list, possibly empty.
- `val` A named list with components to replace corresponding components in `x`.
- `keep.null` If TRUE, NULL elements in `val` become NULL elements in `x`. Otherwise, the corresponding element, if present, is deleted from `x`.

**Value**

A modified version of `x`, with the modifications determined as follows (here, list elements are identified by their names). Elements in `val` which are missing from `x` are added to `x`. For elements that are common to both but are not both lists themselves, the component in `x` is replaced (or possibly deleted, depending on the value of `keep.null`) by the one in `val`. For common elements that are in both lists, `x[[name]]` is replaced by `modifyList(x[[name]], val[[name]])`.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**Examples**

```r
foo <- list(a = 1, b = list(c = "a", d = FALSE))
bar <- modifyList(foo, list(e = 2, b = list(d = TRUE)))
str(foo)
str(bar)
```

**news**

*Build and Query R or Package News Information*

**Description**

Build and query the news for R or add-on packages.

**Usage**

```r
news(query, package = "R", lib.loc = NULL, format = NULL, reader = NULL, db = NULL)
```
Arguments

query an expression for selecting news entries
package a character string giving the name of an installed add-on package, or "R".
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.
format Not yet used.
reader Not yet used.
db a news db obtained from news().

Details

If package is "R" (default), a news db is built with the news since the 3.0.0 release of R (corresponding to R’s top-level ‘NEWS’ file). Otherwise, if the given add-on package can be found in the given libraries, it is attempted to read its news in structured form from files ‘inst/NEWS.Rd’, ‘NEWS’ or ‘inst/NEWS’ (in that order).

File ‘inst/NEWS.Rd’ should be an Rd file given the entries as Rd \itemize lists, grouped according to version using section elements with names starting with a suitable prefix (e.g. “Changes in version” followed by a space and the version number, and optionally followed by a space and a parenthesized ISO 8601 (%Y-%m-%d, see \strptime) format date, and possibly further grouped according to categories using \subsection elements named as the categories.

The plain text ‘NEWS’ files in add-on packages use a variety of different formats; the default news reader should be capable to extract individual news entries from a majority of packages from the standard repositories, which use (slight variations of) the following format:

- Entries are grouped according to version, with version header “Changes in version” at the beginning of a line, followed by a version number, optionally followed by an ISO 8601 format date, possibly parenthesized.
- Entries may be grouped according to category, with a category header (different from a version header) starting at the beginning of a line.
- Entries are written as itemize-type lists, using one of ‘®’, ‘J’, ‘M’ or ‘K’ as item tag. Entries must be indented, and ideally use a common indentation for the item texts.

Additional formats and readers may be supported in the future.

Package tools provides an (internal) utility function news2Rd to convert plain text ‘NEWS’ files to Rd. For ‘NEWS’ files in a format which can successfully be handled by the default reader, package maintainers can use tools::news2Rd(dir, "NEWS.Rd"), possibly with additional argument codify = TRUE, with dir a character string specifying the path to a package’s root directory. Upon success, the ‘NEWS.Rd’ file can further be improved and then be moved to the ‘inst’ subdirectory of the package source directory.

The news db built is a character data frame inheriting from “news_db” with variables Version, Category, Date and Text, where the last contains the entry texts read, and the other variables may be NA if they were missing or could not be determined.

Using query, one can select news entries from the db. If missing or NULL, the complete db is returned. Otherwise, query should be an expression involving (a subset of) the variables Version, Category, Date and Text, and when evaluated within the db returning a logical vector with length the number of entries in the db. The entries for which evaluation gave TRUE are selected. When evaluating, Version and Date are coerced to numeric_version and Date objects, respectively, so that the comparison operators for these classes can be employed.
Value

An data frame inheriting from class "news_db".

Examples

```r
## Build a db of all R news entries.
db <- news()

## Bug fixes with PR number in 3.0.1.
news(Version == "3.0.1" & grepl("^BUG", Category) & grepl("PR#", Text),
     db = db)
## Which categories have been in use? % R-core maybe should standardize a bit more
sort(table(db[, "Category"]), decreasing = TRUE)
## Entries with version >= 3.0.0 (including "3.0.0 patched").
table(news(Version >= "3.0.0", db = db)$Version)
```

---

**ns1**

*Look up the IP Address by Hostname*

**Description**

Interface to `gethostbyname`.

**Usage**

```r
ns1(hostname)
```

**Arguments**

- `hostname` the name of the host.

**Details**

This was included as a test of internet connectivity, to fail if the node running R is not connected. It will also return `NULL` if BSD networking is not supported, including the header file `arpa/inet.h`.

This function is not available on Windows.

**Value**

The IP address, as a character string, or `NULL` if the call fails.

**Examples**

```r
## Not run: ns1("www.r-project.org")
```
Report the Space Allocated for an Object

### Description

Provides an estimate of the memory that is being used to store an \texttt{R} object.

### Usage

\begin{verbatim}
object.size(x)

## S3 method for class 'object.size'
format(x, units = "b", ...)

## S3 method for class 'object.size'
print(x, quote = FALSE, units = "b", ...)
\end{verbatim}

### Arguments

- \texttt{x}: An \texttt{R} object.
- \texttt{quote}: logical, indicating whether or not the result should be printed with surrounding quotes.
- \texttt{units}: The units to be used in printing the size. Allowed values are "b", "Kb", "Mb", "Gb", "B", "KB", "MB", "GB", and "auto" (see 'Details').
- \texttt{...}: Arguments to be passed to or from other methods.

### Details

Exactly which parts of the memory allocation should be attributed to which object is not clear-cut. This function merely provides a rough indication: it should be reasonably accurate for atomic vectors, but does not detect if elements of a list are shared, for example. (Sharing amongst elements of a character vector is taken into account, but not that between character vectors in a single object.)

The calculation is of the size of the object, and excludes the space needed to store its name in the symbol table.

Associated space (e.g., the environment of a function and what the pointer in a \texttt{EXTPTRSXP} points to) is not included in the calculation.

Object sizes are larger on 64-bit builds than 32-bit ones, but will very likely be the same on different platforms with the same word length and pointer size.

\texttt{units = "auto"} in the \texttt{format} and \texttt{print} methods chooses the largest units in which the result is one or more (before rounding). Values in kilobytes, megabytes or gigabytes are rounded to the nearest 0.1.

### Value

An object of class "object.size" with a length-one double value, an estimate of the memory allocation attributable to the object in bytes.

### See Also

\texttt{Memory-limits} for the design limitations on object size.
Examples

```r
object.size(letters)
object.size(ls)
format(object.size(library), units = "auto")
## find the 10 largest objects in the base package
z <- sapply(ls("package:base"), function(x)
  object.size(get(x, envir = baseenv())))
as.matrix(rev(sort(z))[1:10])
```

package.skeleton

Create a Skeleton for a New Source Package

Description

package.skeleton automates some of the setup for a new source package. It creates directories, saves functions, data, and R code files to appropriate places, and creates skeleton help files and a 'Read-and-delete-me' file describing further steps in packaging.

Usage

```r
package.skeleton(name = "anRpackage", list,
  environment = .GlobalEnv,
  path = ".", force = FALSE,
  code_files = character())
```

Arguments

- `name`: character string: the package name and directory name for your package.
- `list`: character vector naming the R objects to put in the package. Usually, at most one of list, environment, or code_files will be supplied. See ‘Details’.
- `environment`: an environment where objects are looked for. See ‘Details’.
- `path`: path to put the package directory in.
- `force`: If FALSE will not overwrite an existing directory.
- `code_files`: a character vector with the paths to R code files to build the package around. See ‘Details’.

Details

The arguments list, environment, and code_files provide alternative ways to initialize the package. If code_files is supplied, the files so named will be sourced to form the environment, then used to generate the package skeleton. Otherwise list defaults to the objects in environment (including those whose names start with .), but can be supplied to select a subset of the objects in that environment.

Stubs of help files are generated for functions, data objects, and S4 classes and methods, using the `prompt`, `promptClass`, and `promptMethods` functions. If an object from another package is intended to be imported and re-exported without changes, the `promptImport` function should be used after `package.skeleton` to generate a simple help file linking to the original one.

The package sources are placed in subdirectory name of path. If code_files is supplied, these files are copied; otherwise, objects will be dumped into individual source files. The file names in code_files should have suffix ".R" and be in the current working directory.
The filenames created for source and documentation try to be valid for all OSes known to run R. Invalid characters are replaced by '_', invalid names are preceded by 'zz', names are converted to lower case (to avoid case collisions on case-insensitive file systems) and finally the converted names are made unique by `make.unique(sep = "_")`. This can be done for code and help files but not data files (which are looked for by name). Also, the code and help files should have names starting with an ASCII letter or digit, and this is checked and if necessary z prepended.

Functions with names starting with a dot are placed in file ‘R/name-internal.R’.

When you are done, delete the ‘Read-and-delete-me’ file, as it should not be distributed.

**Value**

Used for its side-effects.

**References**

Read the ‘Writing R Extensions’ manual for more details.

Once you have created a source package you need to install it: see the ‘R Installation and Administration’ manual, `install` and `install.packages`.

**See Also**

`prompt`, `promptClass`, and `promptMethods`.

**Examples**

```r
require(stats)
## two functions and two "data sets":
f <- function(x, y) x+y
g <- function(x, y) x-y
d <- data.frame(a = 1, b = 2)
e <- rnorm(1000)
package.skeleton(list = c("f","g","d","e"), name = "mypkg")
```

---

**packageDescription**

*Package Description*

**Description**

Parses and returns the ‘DESCRIPTION’ file of a package.

**Usage**

```r
packageDescription(pkg, lib.loc = NULL, fields = NULL,
drop = TRUE, encoding = "")
packageVersion(pkg, lib.loc = NULL)
```
Arguments

pkg a character string with the package name.
lib.loc a character vector of directory names of \textit{R} libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages and namespaces are searched before the libraries.
fields a character vector giving the tags of fields to return (if other fields occur in the file they are ignored).
drop If \texttt{TRUE} and the length of \texttt{fields} is 1, then a single character string with the value of the respective field is returned instead of an object of class "packageDescription".
encoding If there is an Encoding field, to what encoding should re-encoding be attempted? If \texttt{NA}, no re-encoding. The other values are as used by \texttt{iconv}, so the default \texttt{""} indicates the encoding of the current locale.

Details

A package will not be ‘found’ unless it has a ‘DESCRIPTION’ file which contains a valid \texttt{Version} field. Different warnings are given when no package directory is found and when there is a suitable directory but no valid ‘DESCRIPTION’ file.

An attached environment named to look like a package (e.g., \texttt{package:utils2}) will be ignored.

\texttt{packageVersion()} is a convenience shortcut, allowing things like if (\texttt{packageVersion("MASS") < "7.3"}) \{ do.things \}.

Value

If a ‘DESCRIPTION’ file for the given package is found and can successfully be read, \texttt{packageDescription} returns an object of class "packageDescription", which is a named list with the values of the (given) fields as elements and the tags as names, unless \texttt{drop} = \texttt{TRUE}.

If parsing the ‘DESCRIPTION’ file was not successful, it returns a named list of NAs with the field tags as names if \texttt{fields} is not null, and NA otherwise.

\texttt{packageVersion()} returns a (length-one) object of class "package_version".

See Also

\texttt{read.dcf}

Examples

\begin{verbatim}
packageDescription("stats")
packageDescription("stats", fields = c("Package", "Version"))

packageDescription("stats", fields = "Version")
packageDescription("stats", fields = "Version", drop = FALSE)

if(packageVersion("MASS") < "7.3.29")
  message("you need to update 'MASS'!")
\end{verbatim}
packageName

*Find package associated with an environment.*

**Description**

Many environments are associated with a package; this function attempts to determine that package.

**Usage**

```
packageName(env = parent.frame())
```

**Arguments**

- `env` The environment whose name we seek.

**Details**

Environment `env` would be associated with a package if `topenv(env)` is the namespace environment for that package. Thus when `env` is the environment associated with functions inside a package, or local functions defined within them, `packageName` will normally return the package name.

Not all environments are associated with a package: for example, the global environment, or the evaluation frames of functions defined there. `packageName` will return `NULL` in these cases.

**Value**

A length one character vector containing the name of the package, or `NULL` if there is no name.

**See Also**

`getPackageName` is a more elaborate function that can construct a name if none is found.

**Examples**

```
packageName()
packageName(environment(mean))
```

---

packageStatus

*Package Management Tools*

**Description**

Summarize information about installed packages and packages available at various repositories, and automatically upgrade outdated packages.
packageStatus

Usage

packageStatus(lib.loc = NULL, repositories = NULL, method, type =getOption("pkgType"))

## S3 method for class 'packageStatus'
summary(object, ...)

## S3 method for class 'packageStatus'
update(object, lib.loc = levels(object$inst$LibPath),
       repositories = levels(object$avail$Repository), ...)

## S3 method for class 'packageStatus'
upgrade(object, ask = TRUE, ...)

Arguments

lib.loc a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.

repositories a character vector of URLs describing the location of R package repositories on the Internet or on the local machine.

method Download method, see download.file.

type type of package distribution: see install.packages.

object an object of class "packageStatus" as returned by packageStatus.

ask if TRUE, the user is prompted which packages should be upgraded and which not.

... currently not used.

Details

The URLs in repositories should be full paths to the appropriate contrib sections of the repositories. The default is contrib.url(getOption("repos")).

There are print and summary methods for the "packageStatus" objects: the print method gives a brief tabular summary and the summary method prints the results.

The update method updates the "packageStatus" object. The upgrade method is similar to update.packages: it offers to install the current versions of those packages which are not currently up-to-date.

Value

An object of class "packageStatus". This is a list with two components

inst a data frame with columns as the matrix returned by installed.packages plus "Status", a factor with levels c("ok", "upgrade"). Only the newest version of each package is reported, in the first repository in which it appears.

avail a data frame with columns as the matrix returned by available.packages plus "Status", a factor with levels c("installed", "not installed", "unavailable").

For the summary method the result is also of class "summary.packageStatus" with additional components
Libs a list with one element for each library
Repos a list with one element for each repository

with the elements being lists of character vectors of package name for each status.

See Also

installed.packages, available.packages

Examples

## Not run:
x <- packageStatus()
print(x)
summary(x)
upgrade(x)
x <- update(x)
print(x)

## End(Not run)
Examples

## Not run: ## four ways to look at the code of 'page'
page("page")  # as an object
page("page")  # a character string
v <- "page"; page(v)  # a length-one character vector
page(utils::page)  # a call

## End(Not run)

### Description

A class and utility methods for holding information about persons like name and email address.

### Usage

```r
person(given = NULL, family = NULL, middle = NULL,
       email = NULL, role = NULL, comment = NULL,
       first = NULL, last = NULL)
```

**# Default S3 method:**
```r
as.person(x)
```

**# S3 method for class 'person'**
```r
format(x,  
include = c("given", "family", "email", "role", "comment"),  
braces = list(given = "", family = "", email = c("<", ">"),  
role = c("[", "]"), comment = c("("", ")")),  
collapse = list(given = " ", family = " ", email = " ",  
role = " ", comment = " "),  
...  
)
```

### Arguments

- **given** a character vector with the *given* names, or a list thereof.
- **family** a character string with the *family* name, or a list thereof.
- **middle** a character string with the collapsed middle name(s). Deprecated, see Details.
- **email** a character string giving the email address, or a list thereof.
- **role** a character string specifying the role of the person (see Details), or a list thereof.
- **comment** a character string providing a comment, or a list thereof.
- **first** a character string giving the first name. Deprecated, see Details.
- **last** a character string giving the last name. Deprecated, see Details.
- **x** a character string for the as.person default method; an object of class "person" otherwise.
- **include** a character vector giving the fields to be included when formatting.
- **braces** a list of characters (see Details).
- **collapse** a list of characters (see Details).
- **...** currently not used.
Details

Objects of class "person" can hold information about an arbitrary positive number of persons. These can be obtained by one call to `person()` with list arguments, or by first creating objects representing single persons and combining these via `c()`. The `format()` method collapses information about persons into character vectors (one string for each person): the fields in `inc«ude` are selected, each collapsed to a string using the respective element of `collapse` and subsequently “embraced” using the respective element of `braces`, and finally collapsed into one string separated by white space. If `braces` and/or `collapse` do not specify characters for all fields, the defaults shown in the usage are imputed. The `print()` method calls the `format()` method and prints the result, the `toBibtex()` method creates a suitable BibTeX representation.

Person objects can be subscripted by fields (using `()`) or by position (using `[]`). `as.person()` is a generic function. Its default method tries to reverse the default person formatting, and can also handle formatted person entries collapsed by comma or "and" (with appropriate white space).

Personal names are rather tricky, e.g., http://en.wikipedia.org/wiki/Personal_name.

The current implementation (starting from R 2.12.0) of the "person" class uses the notions of `given` (including middle names) and `family` names, as specified by `given` and `family` respectively. Earlier versions used a scheme based on first, middle and last names, as appropriate for most of Western culture where the given name precedes the family name, but not universal, as some other cultures place it after the family name, or use no family name. To smooth the transition to the new scheme, arguments `first`, `middle` and `last` are still supported, but their use is deprecated and they must not be given in combination with the corresponding new style arguments.

The new scheme also adds the possibility of specifying `roles` based on a subset of the MARC Value List for Relators and Roles (http://www.loc.gov/standards/source/relator-role.html). When giving the roles of persons in the context of authoring R packages, the following usage is suggested.

"aut" (Author) Use for full authors who have made substantial contributions to the package and should show up in the package citation.

"com" (Compiler) Use for persons who collected code (potentially in other languages) but did not make further substantial contributions to the package.

"ctb" (Contributor) Use for authors who have made smaller contributions (such as code patches etc.) but should not show up in the package citation.

"cph" (Copyright holder) Use for all copyright holders.

"cre" (Creator) Use for the package maintainer.

"ths" (Thesis advisor) If the package is part of a thesis, use for the thesis advisor.

"trl" (Translator) If the R code is a translation from another language (typically S), use for the translator to R.

In the old scheme, person objects were used for single persons, and a separate "personList" class with corresponding creator `personList()` for collections of these. The new scheme employs a single class for information about an arbitrary positive number of persons, eliminating the need for the `personList` mechanism.

Value

`person()` and `as.person()` return objects of class "person".

citation

Examples

## Create a person object directly ...
```r
p1 <- person("Karl", "Pearson", email = "pearson@stats.heaven")
```

## ... or convert a string.
```r
p2 <- as.person("Ronald Aylmer Fisher")
```

## Combining and subsetting.
```r
p <- c(p1, p2)
p[1]
p[-1]
```

## Extracting fields.
```r
p$family
p$email
p$[1]$email
```

## Specifying package authors, example from "boot":
## AC is the first author [aut] who wrote the S original.
## BR is the second author [aut], who translated the code to R [trl],
## and maintains the package [cre].
```r
person(c("Brian", "D.", "Ripley", role = c("aut", "trl", "cre"),
    comment = "R port", email = "ripley@stats.ox.ac.uk"),
)
```
```r
b
```

## Formatting.
```r
format(b)
format(b, include = c("family", "given", "role"),
    braces = list(family = c("", ","), role = c("(Role(s): ", ")"))
```

toBibtex(b)
```

PkgUtils

Utilities for Building and Checking Add-on Packages

Description

Utilities for checking whether the sources of an R add-on package work correctly, and for building a source package from them.

Usage

R CMD check [options] pkgdirs
R CMD build [options] pkgdirs
process.events

Arguments

pkgdirs a list of names of directories with sources of R add-on packages. For check these can also be the filenames of compressed tar archives with extension '.tar.gz', '.tgz', '.tar.bz2' or '.tar.xz'.

options further options to control the processing, or for obtaining information about usage and version of the utility.

Details

R CMD check checks R add-on packages from their sources, performing a wide variety of diagnostic checks.

R CMD build builds R source tarballs. The name(s) of the packages are taken from the 'DESCRIPTION' files and not from the directory names. This works entirely on a copy of the supplied source directories.

Use R CMD foo --help to obtain usage information on utility foo.

The defaults for some of the options to R CMD build can be set by environment variables _R_BUILD_RESAVE_DATA_ and _R_BUILD_COMPACT_VIGNETTES_: see ‘Writing R Extensions’. Many of the checks in R CMD check can be turned off or on by environment variables: see Chapter 6 of the ‘R Internals’ manual.

By default R CMD build uses the “internal” option to tar to prepare the tarball. An external tar program can be specified by the R_BUILD_TAR environment variable. This may be substantially faster for very large packages, and can be needed for packages with long path names (over 100 bytes) or very large files (over 8GB): however, the resulting tarball may not be portable.

R CMD check by default unpacks tarballs by the internal untar function: if needed an external tar command can be specified by the environment variable R_INSTALL_TAR: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting R_INSTALL_TAR to ‘tar.exe’ has been needed to overcome permissions issues on some Windows systems.)

process.events

Trigger event handling

Description

R front ends like the Windows GUI handle key presses and mouse clicks through “events” generated by the OS. These are processed automatically by R at intervals during computations, but in some cases it may be desirable to trigger immediate event handling. The process.events function does that.

Usage

process.events()
Details

This is a simple wrapper for the C API function `r_processEvents`. As such, it is possible that it will not return if the user has signalled to interrupt the calculation.

Value

`NULL` is returned invisibly.

Author(s)

Duncan Murdoch

See Also

See ‘Writing R Extensions’ and the ‘R for Windows FAQ’ for more discussion of the `r_processEvents` function.

Description

Facilitate the constructing of files documenting R objects.

Usage

```r
prompt(object, filename = NULL, name = NULL, ...)  
## Default S3 method:
prompt(object, filename = NULL, name = NULL,  
   force.function = FALSE, ...)

## S3 method for class 'data.frame'
prompt(object, filename = NULL, name = NULL, ...)

promptImport(object, filename = NULL, name = NULL,  
   importedFrom = NULL, importPage = name, ...)
```

Arguments

- **object**
  - an R object, typically a function for the default method. Can be `missing` when name is specified.
- **filename**
  - usually, a `connection` or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is `name` followed by ".Rd". Can also be `NA` (see below).
- **name**
  - a character string specifying the name of the object.
- **force.function**
  - a logical. If TRUE, treat `object` as function in any case.
- **...**
  - further arguments passed to or from other methods.
- **importedFrom**
  - a character string naming the package from which `object` was imported. Defaults to the environment of `object` if `object` is a function.
- **importPage**
  - a character string naming the help page in the package from which `object` was imported.
Details

Unless `filename` is `NA`, a documentation shell for `object` is written to the file specified by `filename`, and a message about this is given. For function objects, this shell contains the proper function and argument names. R documentation files thus created still need to be edited and moved into the `‘man’` subdirectory of the package containing the object to be documented.

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"),` where `x` is the list-style representation.

When `prompt` is used in `for` loops or scripts, the explicit name specification will be useful.

The `importPage` argument for `promptImport` needs to give the base of the name of the help file of the original help page. For example, the `approx` function is documented in `‘approxfun.Rd’` in the `stats` package, so if it were imported and re-exported it should have `importPage = “approxfun”`. Objects that are imported from other packages are not normally documented unless re-exported.

Value

If `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

Warning

The default filename may not be a valid filename under limited file systems (e.g., those on Windows).

Currently, calling `prompt` on a non-function object assumes that the object is in fact a data set and hence documents it as such. This may change in future versions of R. Use `promptData` to create documentation skeletons for data sets.

Note

The documentation file produced by `prompt.data.frame` does not have the same format as many of the data frame documentation files in the `base` package. We are trying to settle on a preferred format for the documentation.

Author(s)

Douglas Bates for `prompt.data.frame`

promptData

Generate Outline Documentation for a Data Set

Description
Generates a shell of documentation for a data set.

Usage
promptData(object, filename = NULL, name = NULL)

Arguments
object
an R object to be documented as a data set.
filename
usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by ".Rd". Can also be NA (see below).
name
a character string specifying the name of the object.

Details
Unless filename is NA, a documentation shell for object is written to the file specified by filename, and a message about this is given.
If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "n"),` where x is the list-style representation.
Currently, only data frames are handled explicitly by the code.

Value
If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.
promptPackage

See Also

prompt

Examples

promptData(sunspots)
unlink("sunspots.Rd")

Description

Generates a shell of documentation for an installed or source package.

Usage

promptPackage(package, lib.loc = NULL, filename = NULL,
    name = NULL, final = FALSE)

Arguments

package  a character string with the name of an installed or source package to be documented.
lib.loc  a character vector describing the location of \textit{R} library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known. For a source package this should specify the parent directory of the package’s sources.
filename  usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by ".Rd". Can also be \texttt{NA} (see below).
name  a character string specifying the name of the help topic, typically of the form \texttt{\textbackslash{pkg} \textbackslash{-package}}.
final  a logical value indicating whether to attempt to create a usable version of the help topic, rather than just a shell.

Details

Unless filename is \texttt{NA}, a documentation shell for package is written to the file specified by filename, and a message about this is given.

If filename is \texttt{NA}, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to \texttt{cat(unlist(x), file = filename, sep = \texttt{"n"}),} where \texttt{x} is the list-style representation.

If final is \texttt{TRUE}, the generated documentation will not include the place-holder slots for manual editing, it will be usable as-is. In most cases a manually edited file is preferable (but final = \texttt{TRUE} is certainly less work).
Value

If `filename` is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

See Also

`prompt`

Examples

```r
filename <- tempfile()
promptPackage("utils", filename = filename)
file.show(filename)
unlink(filename)
```

Description

These functions provide access to documentation. Documentation on a topic with name `name` (typically, an R object or a data set) can be displayed by either `help("name")` or `?name`.

Usage

```r
?topic

`type?topic`
```

Arguments

- `topic`: Usually, a `name` or character string specifying the topic for which help is sought. Alternatively, a function call to ask for documentation on a corresponding S4 method: see the section on S4 method documentation. The calls `pkg:::topic` and `pkg:::topic` are treated specially, and look for help on `topic` in package `pkg`.

- `type`: the special type of documentation to use for this topic; for example, if the type is `class`, documentation is provided for the class with name `topic`. See the Section ‘S4 Method Documentation’ for the uses of `type` to get help on formal methods, including `methods?function` and `method?call`.

Details

This is a shortcut to `help` and uses its default type of help.

Some topics need to be quoted (by `backticks`) or given as a character string. There include those which cannot syntactically appear on their own such as unary and binary operators, `function` and control-flow `reserved` words (including `if`, `else for, in, repeat, while, break and next`. The other `reserved` words can be used as if they were names, for example `TRUE, NA and Inf`. 
S4 Method Documentation

Authors of formal (‘S4’) methods can provide documentation on specific methods, as well as overall documentation on the methods of a particular function. The "?" operator allows access to this documentation in three ways.

The expression `methods?f` will look for the overall documentation methods for the function `f`. Currently, this means the documentation file containing the alias `f`-methods.

There are two different ways to look for documentation on a particular method. The first is to supply the `topic` argument in the form of a function call, omitting the `type` argument. The effect is to look for documentation on the method that would be used if this function call were actually evaluated. See the examples below. If the function is not a generic (no S4 methods are defined for it), the help reverts to documentation on the function name.

The "?" operator can also be called with `doc_type` supplied as `method`; in this case also, the `topic` argument is a function call, but the arguments are now interpreted as specifying the class of the argument, not the actual expression that will appear in a real call to the function. See the examples below.

The first approach will be tedious if the actual call involves complicated expressions, and may be slow if the arguments take a long time to evaluate. The second approach avoids these issues, but you do have to know what the classes of the actual arguments will be when they are evaluated.

Both approaches make use of any inherited methods; the signature of the method to be looked up is found by using `selectMethod` (see the documentation for `getMethod`).

`help`

`??` for finding help pages on a vague topic.

Examples

```r
?lapply

?f"for"        # but quotes/backticks are needed
?"+"?

?women         # information about data set "women"

## Not run:
require(methods)
## define a S4 generic function and some methods
combo <- function(x, y) c(x, y)
setGeneric("combo")
setMethod("combo", c("numeric", "numeric"), function(x, y) x+y)

## assume we have written some documentation
## for combo, and its methods ....

?combo  # produces the function documentation
```
Description

This page documents a mechanism to generate relevant completions from a partially completed command line. It is not intended to be useful by itself, but rather in conjunction with other mechanisms that use it as a backend. The functions listed in the usage section provide a simple control and query mechanism. The actual interface consists of a few unexported functions described further down.

Usage

```r
rc.settings(ops, ns, args, func, ipck, S3, data, help,
            argdb, fuzzy, quotes, files)
rc.status()
rc.getOpt(name)
rc.options(...)
.DollarNames(x, pattern)
```

## Default S3 method:
.DollarNames(x, pattern = "")
## S3 method for class 'list'
.DollarNames(x, pattern = "")
## S3 method for class 'environment'
.DollarNames(x, pattern = ")"

Arguments

- `ops`, `ns`, `args`, `func`, `ipck`, `S3`, `data`, `help`, `argdb`, `fuzzy`, `quotes`, `files` (logical): turning some optional completion features on and off.
- `ops`: Activates completion after the `$` and `@` operators.
- `ns`: Controls namespace related completions.
- `args`: Enables completion of function arguments.
- `func`: Enables detection of functions. If enabled, a customizable extension (""," by default) is appended to function names. The process of determining whether a potential completion is a function requires evaluation, including
for lazy loaded symbols. This is undesirable for large objects, because of potentially wasteful use of memory in addition to the time overhead associated with loading. For this reason, this feature is disabled by default.

S3: When `args = TRUE`, activates completion on arguments of all S3 methods (otherwise just the generic, which usually has very few arguments).

`ipck`: Enables completion of installed package names inside `library` and `require`.

`data`: Enables completion of data sets (including those already visible) inside `data`.

`help`: Enables completion of help requests starting with a question mark, by looking inside help index files.

`argdb`: When `args = TRUE`, completion is attempted on function arguments. Generally, the list of valid arguments is determined by dynamic calls to `args`. While this gives results that are technically correct, the use of the `...` argument often hides some useful arguments. To give more flexibility in this regard, an optional table of valid arguments names for specific functions is retained internally. Setting `argdb = TRUE` enables preferential lookup in this internal data base for functions with an entry in it. Of course, this is useful only when the data base contains information about the function of interest. Some functions are already included, and more can be added by the user through the exported function `.addFunctionInfo` (see below).

`fuzzy`: Enables fuzzy matching, where close but non-exact matches (e.g., with different case) are considered if no exact matches are found. This feature is experimental and the details can change.

`quotes`: Enables completion in R code when inside quotes. This normally leads to filename completion, but can be otherwise depending on context (for example, when the open quote is preceded by `?`, help completion is invoked. Setting this to `FALSE` relegates completion to the underlying completion front-end, which may do its own processing (for example, `readline` on Unix-alikes will do filename completion.

`files`: Deprecated. Use `quotes` instead.

All settings are turned on by default except `ipck`, `func`, and `fuzzy`. Turn more off if your CPU cycles are valuable; you will still retain basic completion on names of objects in the search list. See below for additional details.

Name, ... user-settable options. Currently valid names are

- `function.suffix`: default `"("`
- `funarg.suffix`: default `" = "`
- `package.suffix` default `"::"`

Usage is similar to that of `options`.

`x` An R object for which valid names after `"$"` are computed and returned.

`pattern` A regular expression. Only matching names are returned.

### Details

There are several types of completion, some of which can be disabled using `rc.settings`. The most basic level, which can not be turned off once the completion functionality is activated, provides completion on names visible on the search path, along with a few special keywords (e.g., `TRUE`). This type of completion is not attempted if the partial ‘word’ (a.k.a. token) being completed is
Completion after extractors $ and @: When the `ops` setting is turned on, completion after $ and @ is attempted. This requires the prefix to be evaluated, which is attempted unless it involves an explicit function call (implicit function calls involving the use of `, $, etc do not inhibit evaluation).

Valid completions after the $ extractor are determined by the generic function `.DollarNames`. Some basic methods are provided, and more can be written for custom classes.

Completion inside namespaces: When the `ns` setting is turned on, completion inside namespaces is attempted when a token is preceded by the `::` or `<<<` operators. Additionally, the basic completion mechanism is extended to include attached namespaces, or more precisely, `foo::pkg` becomes a valid completion of `foo` if the return value of `search()` includes the string “package: foo::pkg”.

The completion of package namespaces applies only to attached packages, i.e. if MASS is not attached (whether or not it is loaded), MA5 will not complete to MASS::. However, attempted completion inside an apparent namespace will attempt to load the namespace if it is not already loaded, e.g. trying to complete on MASS::fr will load MASS (but not necessarily attach it) even if it is not already loaded.

Completion for help items: When the `help` setting is turned on, completion on help topics is attempted when a token is preceded by `. `. Prefixes (such as `class`, `method`) are supported, as well as quoted help topics containing special characters.

Completion of function arguments: When the `args` setting is turned on, completion on function arguments is attempted whenever deemed appropriate. The mechanism used will currently fail if the relevant function (at the point where completion is requested) was entered on a previous prompt (which implies in particular that the current line is being typed in response to a continuation prompt, usually +). Note that separation by newlines is fine.

The list of possible argument completions that is generated can be misleading. There is no problem for non-generic functions (except that `...` is listed as a completion; this is intentional as it signals the fact that the function can accept further arguments). However, for generic functions, it is practically impossible to give a reliable argument list without evaluating arguments (and not even then, in some cases), which is risky (in addition to being difficult to code, which is the real reason it hasn’t even been tried), especially when that argument is itself an inline function call. Our compromise is to consider arguments of all currently available methods of that generic. This has two drawbacks. First, not all listed completions may be appropriate in the call currently being constructed. Second, for generics with many methods (like print and plot), many matches will need to be considered, which may take a noticeable amount of time. Despite these drawbacks, we believe this behaviour to be more useful than the only other practical alternative, which is to list arguments of the generic only.

Only S3 methods are currently supported in this fashion, and that can be turned off using the `S3` setting.

Since arguments can be unnamed in R function calls, other types of completion are also appropriate whenever argument completion is. Since there are usually many more visible objects than formal arguments of any particular function, possible argument completions are often buried in a bunch of other possibilities. However, recall that basic completion is suppressed for blank tokens. This can be useful to list possible arguments of a function. For example, trying to complete `seq([TAB]` and `seq(from = 1, [TAB])` will both list only the arguments of seq (or any of its methods), whereas trying to complete `seq(length[TAB])` will list both the `length` out argument and the `length` function as possible completions. Note that no attempt is made to remove arguments already supplied, as that would incur a further speed penalty.
Special functions: For a few special functions (library, data, etc), the first argument is treated specially, in the sense that normal completion is suppressed, and some function specific completions are enabled if so requested by the settings. The ipck setting, which controls whether library and require will complete on installed packages, is disabled by default because the first call to installed.packages is potentially time consuming (e.g., when packages are installed on a remote network file server). Note, however, that the results of a call to installed.packages is cached, so subsequent calls are usually fast, so turning this option on is not particularly onerous even in such situations.

Value

If rc.settings is called without any arguments, it returns the current settings as a named logical vector. Otherwise, it returns NULL invisibly.

rc.status returns, as a list, the contents of an internal (unexported) environment that is used to record the results of the last completion attempt. This can be useful for debugging. For such use, one must resist the temptation to use completion when typing the call to rc.status itself, as that then becomes the last attempt by the time the call is executed.

The items of primary interest in the returned list are:

- comps: The possible completions generated by the last call to .completeToken, as a character vector.
- token: The token that was (or, is to be) completed, as set by the last call to .assignToken (possibly inside a call to .guessTokenFromLine).
- linebuffer: The full line, as set by the last call to .assignLinebuffer.
- start: The start position of the token in the line buffer, as set by the last call to .assignStart.
- end: The end position of the token in the line buffer, as set by the last call to .assignEnd.
- fileName: Logical, indicating whether the cursor is currently inside quotes.
- fgross: The name of the function the cursor is currently inside.
- isFirstArg: Logical. If cursor is inside a function, is it the first argument?

In addition, the components settings and options give the current values of settings and options respectively.

rc.getOption and rc.options behave much like getopt and options respectively.

Unexported API

There are several unexported functions in the package. Of these, a few are special because they provide the API through which other mechanisms can make use of the facilities provided by this package (they are unexported because they are not meant to be called directly by users). The usage of these functions are:

- .assignToken(text)
- .assignLinebuffer(line)
- .assignStart(start)
- .assignEnd(end)
- .completeToken()
- .retrieveCompletions()
The first four functions set up a completion attempt by specifying the token to be completed (text),
and indicating where (start and end, which should be integers) the token is placed within the
complete line typed so far (line).

Potential completions of the token are generated by .completeToken, and the completions can be
retrieved as an R character vector using .retrieveCompletions.

If the cursor is inside quotes, completion may be suppressed. The function .getFileComp can be
used after a call to .completeToken to determine if this is the case (returns TRUE), and alternative
completions generated as deemed useful. In most cases, filename completion is a reasonable
fallback.

The .guessTokenFromLine function is provided for use with backends that do not already break a
line into tokens. It requires the linebuffer and endpoint (cursor position) to be already set, and itself
sets the token and the start position. It returns the token as a character string.

The .win32consoleCompletion is similar in spirit, but is more geared towards the Windows GUI
(or rather, any front-end that has no completion facilities of its own). It requires the linebuffer
and cursor position as arguments, and returns a list with three components, addition, possible
and comps. If there is an unambiguous extension at the current position, addition contains the
additional text that should be inserted at the cursor. If there is more than one possibility, these are
available either as a character vector of preformatted strings in possible, or as a single string in
comps. possible consists of lines formatted using the current width option, so that printing them
on the console one line at a time will be a reasonable way to list them. comps is a space separated
(collapsed) list of the same completions, in case the front-end wishes to display it in some other
fashion.

The minlength argument can be used to suppress completion when the token is too short (which can
be useful if the front-end is set up to try completion on every keypress). If check.repeat is TRUE,
it is detected if the same completion is being requested more than once in a row, and ambiguous
completions are returned only in that case. This is an attempt to emulate GNU Readline behaviour,
where a single TAB completes up to any unambiguous part, and multiple possibilities are reported
only on two consecutive TABs.

As the various front-end interfaces evolve, the details of these functions are likely to change as well.

The function .addFunctionInfo can be used to add information about the permitted argument
names for specific functions. Multiple named arguments are allowed in calls to it, where the tags
are names of functions and values are character vectors representing valid arguments. When the
argdb setting is TRUE, these are used as a source of valid argument names for the relevant functions.

Note

If you are uncomfortable with unsolicited evaluation of pieces of code, you should set ops = FALSE.
Otherwise, trying to complete Foo@ba will evaluate Foo, trying to complete foo[i, 1:10]$ba will
evaluate foo[i, 1:10], etc. This should not be too bad, as explicit function calls (involving
parentheses) are not evaluated in this manner. However, this will affect promises and lazy loaded
symbols.

read.DIF  Data Input from Spreadsheet

Description

Reads a file in Data Interchange Format (DIF) and creates a data frame from it. DIF is a format for data matrices such as single spreadsheets.

Usage

read.DIF(file, header = FALSE, dec = ".", numerals = c(“allow.loss”, “warn.loss”, “no.loss”), row.names, col.names, as.is = !stringsAsFactors, na.strings = “NA”, colClasses = NA, nrows = -1, skip = 0, check.names = TRUE, blank.lines.skip = TRUE, stringsAsFactors = default.stringsAsFactors(), transpose = FALSE)

Arguments

file  the name of the file which the data are to be read from, or a connection, or a complete URL. The name “clipb®ard” may also be used on Windows, in which case read.DIF(“clipb®ard”) will look for a DIF format entry in the Windows clipb®ard.

header  a logical value indicating whether the spreadsheet contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains only character values and the top left cell is empty.

dec  the character used in the file for decimal points.

numerals  string indicating how to convert numbers whose conversion to double precision would lose accuracy, see type.convert.

row.names  a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names. If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if row.names is missing, the rows are numbered. Using row.names = NULL forces row numbering.

col.names  a vector of optional names for the variables. The default is to use “V” followed by the column number.

as.is  the default behavior of read.DIF is to convert character variables to factors. The variable as.is controls the conversion of columns not otherwise specified by colClasses. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.
Note: In releases prior to R 2.12.1, cells marked as being of character type were converted to logical, numeric or complex using `type.convert` as in `read.table`.

Note: to suppress all conversions including those of numeric columns, set `colClasses = "character"`.

Note that `as.is` is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.

`na.strings` a character vector of strings which are to be interpreted as `NA` values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.

`colClasses` character. A vector of classes to be assumed for the columns. Recycled as necessary, or if the character vector is named, unspecified values are taken to be `NA`.

Possible values are `NA` (when `type.convert` is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an as method (from package `methods`) for conversion from "character" to the specified formal class.

Note that `colClasses` is specified per column (not per variable) and so includes the column of row names (if any).

`nrows` the maximum number of rows to read in. Negative values are ignored.

`skip` the number of lines of the data file to skip before beginning to read data.

`check.names` logical. If `TRUE` then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by `make.names`) so that they are, and also to ensure that there are no duplicates.

`blank.lines.skip` logical: if `TRUE` blank lines in the input are ignored.

`stringsAsFactors` logical: should character vectors be converted to factors?

`transpose` logical, indicating if the row and column interpretation should be transposed. Microsoft’s Excel has been known to produce (non-standard conforming) DIF files which would need `transpose = TRUE` to be read correctly.

**Value**

A data frame (`data.frame`) containing a representation of the data in the file. Empty input is an error unless `col.names` is specified, when a 0-row data frame is returned: similarly giving just a header line if `header = TRUE` results in a 0-row data frame.

**Note**

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).

Less memory will be used if `colClasses` is specified as one of the six atomic vector classes.

**Author(s)**

R Core; `transpose` option by Christoph Buser, ETH Zurich
References

The DIF format specification can be found by searching on http://www.wotsit.org/; the optional header fields are ignored. See also http://en.wikipedia.org/wiki/Data_Interchange_Format.

The term is likely to lead to confusion: Windows will have a ‘Windows Data Interchange Format (DIF) data format’ as part of its WinFX system, which may or may not be compatible.

The R Data Import/Export manual.

scan, type.convert, read.fwf for reading fixed width formatted input; read.table; data.frame.

Examples

```r
## read.DIF() may need transpose = TRUE for a file exported from Excel
udir <- system.file("misc", package = "utils")
dd <- read.DIF(file.path(udir, "exDIF.dif"), header = TRUE, transpose = TRUE)
dc <- read.csv(file.path(udir, "exDIF.csv"), header = TRUE)
stopifnot(identical(dd, dc), dim(dd) == c(4,2))
```

---

### read.fortran

#### Read Fixed-Format Data in a Fortran-like Style

**Description**

Read fixed-format data files using Fortran-style format specifications.

**Usage**

```r
read.fortran(file, format, ..., as.is = TRUE, colClasses = NA)
```

**Arguments**

- `file`  
  File or connection to read from.

- `format`  
  Character vector or list of vectors. See ‘Details’ below.

- `...`  
  Other arguments for `read.fwf`.

- `as.is`  
  Keep characters as characters?

- `colClasses`  
  Variable classes to override defaults. See `read.table` for details.

**Details**

The format for a field is of one of the following forms: `rFl.d, rDl.d, rXl, rAl, rIl`, where `l` is the number of columns, `d` is the number of decimal places, and `r` is the number of repeats. `F` and `D` are numeric formats, `A` is character, `I` is integer, and `X` indicates columns to be skipped. The repeat code `r` and decimal place code `d` are always optional. The length code `l` is required except for `X` formats when `r` is present.

For a single-line record, `format` should be a character vector. For a multiline record it should be a list with a character vector for each line.

Skipped (`X`) columns are not passed to `read.fwf`, so `colClasses`, `col.names`, and similar arguments passed to `read.fwf` should not reference these columns.
Value

A data frame

Note

read.fortran does not use actual Fortran input routines, so the formats are at best rough approximations to the Fortran ones. In particular, specifying $d > 0$ in the F or D format will shift the decimal $d$ places to the left, even if it is explicitly specified in the input file.

See Also

read.fwf, read.table, read.csv

Examples

```r
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fortran(ff, c("F2.1", "F2.0", "I2"))
read.fortran(ff, c("2F1.0", "2X", "2A1"))
unlink(ff)
cat(file = ff, "123456AB", "987654CD", sep = "\n")
read.fortran(ff, list(c("2F3.1", "A2"), c("3I2", "2X")))
unlink(ff)
# Note that the first number is read differently than Fortran would
# read it:
cat(file = ff, "12.3456", "1234567", sep = "\n")
read.fortran(ff, "F7.4")
unlink(ff)
```

Description

Read a table of fixed width formatted data into a `data.frame`.

Usage

```r
read.fwf(file, widths, header = FALSE, sep = "\t",
         skip = 0, row.names, col.names, n = -1,
         buffersize = 2000, ...)
```

Arguments

- **file**: the name of the file which the data are to be read from.
  Alternatively, file can be a connection, which will be opened if necessary, and if so closed at the end of the function call.
- **widths**: integer vector, giving the widths of the fixed-width fields (of one line), or list of integer vectors giving widths for multiline records.
- **header**: a logical value indicating whether the file contains the names of the variables as its first line. If present, the names must be delimited by `sep`. 
sep character; the separator used internally; should be a character that does not occur in the file (except in the header).

skip number of initial lines to skip; see read.table.

row.names see read.table.

col.names see read.table.

n the maximum number of records (lines) to be read, defaulting to no limit.

buffersize Maximum number of lines to read at one time

... further arguments to be passed to read.table. Useful such arguments include as.is, na.strings, colClasses and strip.white.

Details

Multiline records are concatenated to a single line before processing. Fields that are of zero-width or are wholly beyond the end of the line in file are replaced by NA.

Negative-width fields are used to indicate columns to be skipped, e.g., -5 to skip 5 columns. These fields are not seen by read.table and so should not be included in a col.names or colClasses argument (nor in the header line, if present).

Reducing the buffersize argument may reduce memory use when reading large files with long lines. Increasing buffersize may result in faster processing when enough memory is available.

Note that read.fwf (not read.table) reads the supplied file, so the latter’s arguments such as encoding and fileEncoding will not be useful.

Value

A data.frame as produced by read.table which is called internally.

Author(s)

Brian Ripley for R version: originally in Perl by Kurt Hornik.

See Also

scan and read.table.

read.fortran for another style of fixed-format files.

Examples

```r
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = c(1,2,3))  #> 1 23 456 9 87 654
read.fwf(ff, widths = c(1,-2,3))  #> 1 456 9 654
unlink(ff)
cat(file = ff, "123", "987654", sep = "\n")
read.fwf(ff, widths = c(1,0,2,3))  #> 1 NA 23 NA 9 NA 87 654
unlink(ff)
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = list(c(1,0,2,3), c(2,2,2)))  #> 1 NA 23 456 98 76 54
unlink(ff)
```
Description

`read.socket` reads a string from the specified socket, `write.socket` writes to the specified socket. There is very little error checking done by either.

Usage

```r
read.socket(socket, maxlen = 256L, loop = FALSE)
write.socket(socket, string)
```

Arguments

- `socket`: a socket object.
- `maxlen`: maximum length (in bytes) of string to read.
- `loop`: wait for ever if there is nothing to read?
- `string`: string to write to socket.

Value

- `read.socket` returns the string read as a length-one character vector.
- `write.socket` returns the number of bytes written.

`close.socket, make.socket`

Examples

```r
finger <- function(user, host = "localhost", port = 79, print = TRUE) {
  if (!is.character(user))
    stop("user name must be a string")
  user <- paste(user, \\
    user <- make.socket(host, port)
  on.exit(close.socket(socket))
  write.socket(socket, user)
  output <- character(0)
  repeat{
    ss <- read.socket(socket)
    if (ss == "") break
    output <- paste(output, ss)
  }
  close.socket(socket)
  if (print) cat(output)
  invisible(output)
}
```
## read.table

### Data Input

**Description**

Reads a file in table format and creates a data frame from it, with cases corresponding to lines and variables to fields in the file.

**Usage**

```r
read.table(file, header = FALSE, sep = "\", quote = "\\\",
            dec = ".", numerals = c("allow.loss", "warn.loss", "no.loss"),
            row.names, col.names, as.is = !stringsAsFactors,
            na.strings = "NA", colClasses = NA, nroows = -1,
            skip = 0, check.names = TRUE, fill = !blank.lines.skip,
            strip.white = FALSE, blank.lines.skip = TRUE,
            comment.char = "#",
            allowEscapes = FALSE, flush = FALSE,
            stringsAsFactors = default.stringsAsFactors(),
            fileEncoding = ".", encoding = "unknown", text, skipNul = FALSE)
```

```r
read.csv(file, header = TRUE, sep = ",", quote = "\\",
          dec = ".", fill = TRUE, comment.char = ",", ...)
```

```r
read.csv2(file, header = TRUE, sep = ":", quote = "\\",
          dec = ",", fill = TRUE, comment.char = ",", ...)
```

```r
read.delim(file, header = TRUE, sep = "\t", quote = "\\",
            dec = ",", fill = TRUE, comment.char = ",", ...)
```

```r
read.delim2(file, header = TRUE, sep = "\t", quote = "\\",
             dec = ",", fill = TRUE, comment.char = ",", ...)
```

### Arguments

- **file**: the name of the file which the data are to be read from. Each row of the table appears as one line of the file. If it does not contain an *absolute* path, the file name is *relative* to the current working directory, `getwd()`. Tilde-expansion is performed where supported. This can be a compressed file (see `file`). Alternatively, `file` can be a readable text-mode *connection* (which will be opened for reading if necessary, and if so *closed* (and hence destroyed) at the end of the function call). (If `stdin()` is used, the prompts for lines may be somewhat confusing. Terminate input with a blank line or an EOF signal, Ctrl-D on Unix and Ctrl-Z on Windows. Any pushback on `stdin()` will be cleared before return.)

- `file` can also be a complete URL. (For the supported URL schemes, see the ‘URLs’ section of the help for `url`.)
header

A logical value indicating whether the file contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains one fewer field than the number of columns.

sep

The field separator character. Values on each line of the file are separated by this character. If `sep = ""` (the default for `read.table`) the separator is ‘white space’, that is one or more spaces, tabs, newlines or carriage returns.

quote

The set of quoting characters. To disable quoting altogether, use `quote = ""`. See `scan` for the behaviour on quotes embedded in quotes. Quoting is only considered for columns read as character, which is all of them unless `colClasses` is specified.

dec

The character used in the file for decimal points.

numerals

String indicating how to convert numbers whose conversion to double precision would lose accuracy, see `type.convert`.

row.names

A vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names. If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if `row.names` is missing, the rows are numbered.

Using `row.names = NULL` forces row numbering. Missing or `NULL` `row.names` generate row names that are considered to be ‘automatic’ (and not preserved by `as.matrix`).

col.names

A vector of optional names for the variables. The default is to use "V" followed by the column number.

as.is

The default behavior of `read.table` is to convert character variables (which are not converted to logical, numeric or complex) to factors. The variable `as.is` controls the conversion of columns not otherwise specified by `colClasses`. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.

Note: to suppress all conversions including those of numeric columns, set `colClasses = "character"`.

Note that `as.is` is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.

na.strings

A character vector of strings which are to be interpreted as `NA` values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.

colClasses

Character. A vector of classes to be assumed for the columns. Recycled as necessary, or if the character vector is named, unspecified values are taken to be `NA`.

Possible values are `NA` (the default, when `type.convert` is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an as method (from package `methods`) for conversion from "character" to the specified formal class.

Note that `colClasses` is specified per column (not per variable) and so includes the column of row names (if any).
read.table

- **nrows**: integer: the maximum number of rows to read in. Negative and other invalid values are ignored.
- **skip**: integer: the number of lines of the data file to skip before beginning to read data.
- **check.names**: logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by `make.names`) so that they are, and also to ensure that there are no duplicates.
- **fill**: logical. If TRUE then in case the rows have unequal length, blank fields are implicitly added. See ‘Details’.
- **strip.white**: logical. Used only when `sep` has been specified, and allows the stripping of leading and trailing white space from unquoted character fields (numeric fields are always stripped). See `scan` for further details (including the exact meaning of ‘white space’), remembering that the columns may include the row names.
- **blank.lines.skip**: logical: if TRUE blank lines in the input are ignored.
- **comment.char**: character: a character vector of length one containing a single character or an empty string. Use "" to turn off the interpretation of comments altogether.
- **allowEscapes**: logical. Should C-style escapes such as \n be processed or read verbatim (the default)? Note that if not within quotes these could be interpreted as a delimiter (but not as a comment character). For more details see `scan`.
- **flush**: logical: if TRUE, `scan` will flush to the end of the line after reading the last of the fields requested. This allows putting comments after the last field.
- **stringsAsFactors**: logical: should character vectors be converted to factors? Note that this is overridden by `as.is` and `colClasses`, both of which allow finer control.
- **fileEncoding**: character string: if non-empty declares the encoding used on a file (not a connection) so the character data can be re-encoded. See the ‘Encoding’ section of the help for `file`, the ‘R Data Import/Export Manual’ and ‘Note’.
- **encoding**: encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1 or UTF-8 (see `Encoding`): it is not used to re-encode the input, but allows R to handle encoded strings in their native encoding (if one of those two). See ‘Value’ and ‘Note’.
- **text**: character string: if `file` is not supplied and this is, then data are read from the value of `text` via a text connection. Notice that a literal string can be used to include (small) data sets within R code.
- **skipNul**: logical: should nulls be skipped?

Details

This function is the principal means of reading tabular data into R.

Unless `colClasses` is specified, all columns are read as character columns and then converted using `type.convert` to logical, integer, numeric, complex or (depending on `as.is`) factor as appropriate. Quotes are (by default) interpreted in all fields, so a column of values like "42" will result in an integer column.

A field or line is ‘blank’ if it contains nothing (except whitespace if no separator is specified) before a comment character or the end of the field or line.
If `row.names` is not specified and the header line has one less entry than the number of columns, the first column is taken to be the row names. This allows data frames to be read in from the format in which they are printed. If `row.names` is specified and does not refer to the first column, that column is discarded from such files.

The number of data columns is determined by looking at the first five lines of input (or the whole file if it has less than five lines), or from the length of `col.names` if it is specified and is longer. This could conceivably be wrong if `fill` or `blank.lines.skip` are true, so specify `col.names` if necessary (as in the 'Examples').

`read.csv` and `read.csv2` are identical to `read.table` except for the defaults. They are intended for reading 'comma separated value' files ('.csv') or (read.csv2) the variant used in countries that use a comma as decimal point and a semicolon as field separator. Similarly, `read.delim` and `read.delim2` are for reading delimited files, defaulting to the TAB character for the delimiter. Notice that `header = TRUE` and `fill = TRUE` in these variants, and that the comment character is disabled.

The rest of the line after a comment character is skipped; quotes are not processed in comments. Complete comment lines are allowed provided `blank.lines.skip = TRUE`; however, comment lines prior to the header must have the comment character in the first non-blank column.

Quoted fields with embedded newlines are supported except after a comment character. Embedded nulls are unsupported: skipping them (with `skipNu1 = TRUE`) may work.

**Value**

A data frame (`data.frame`) containing a representation of the data in the file.

Empty input is an error unless `col.names` is specified, when a 0-row data frame is returned: similarly giving just a header line if `header = TRUE` results in a 0-row data frame. Note that in either case the columns will be logical unless `colClasses` was supplied.

Character strings in the result (including factor levels) will have a declared encoding if `encoding` is "latin1" or "UTF-8".

**Memory usage**

These functions can use a surprising amount of memory when reading large files. There is extensive discussion in the ‘R Data Import/Export’ manual, supplementing the notes here.

Less memory will be used if `colClasses` is specified as one of the six atomic vector classes. This can be particularly so when reading a column that takes many distinct numeric values, as storing each distinct value as a character string can take up to 14 times as much memory as storing it as an integer.

Using `nrows`, even as a mild over-estimate, will help memory usage.

Using `comment.char = ""` will be appreciably faster than the `read.table` default.

`read.table` is not the right tool for reading large matrices, especially those with many columns: it is designed to read data frames which may have columns of very different classes. Use `scan` instead for matrices.

**Note**

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).

There are two approaches for reading input that is not in the local encoding. If the input is known to be UTF-8 or Latin1, use the `encoding` argument to declare that. If the input is in some other encoding, then it may be translated on input. The `fileEncoding` argument achieves this by setting
up a connection to do the re-encoding into the current locale. Note that on Windows or other systems not running in a UTF-8 locale, this may not be possible.

References

See Also

The ‘R Data Import/Export’ manual.

`scan`, `type.convert`, `read.fwf` for reading fixed width formatted input; `write.table`; `data.frame`.

`count.fields` can be useful to determine problems with reading files which result in reports of incorrect record lengths (see the ‘Examples’ below).

`http://tools.ietf.org/html/rfc4180` for the IANA definition of CSV files (which requires comma as separator and CRLF line endings).

Examples

```r
## using count.fields to handle unknown maximum number of fields
## when fill = TRUE
test1 <- c(1:5, "6,7", "8,9,10")
tf <- tempfile()
writeLines(test1, tf)

read.csv(tf, fill = TRUE) # 1 column
ncol <- max(count.fields(tf, sep = ","))
read.csv(tf, fill = TRUE, header = FALSE,
          col.names = paste("V", seq_len(ncol)))
unlink(tf)

## "Inline" data set, using text=
## Notice that leading and trailing empty lines are auto-trimmed

read.table(header = TRUE, text = "
a b
col 2
3 4
"")
```

### recover

**Browsing after an Error**

**Description**

This function allows the user to browse directly on any of the currently active function calls, and is suitable as an error option. The expression `options(error = recover)` will make this the error option.

**Usage**

`recover()`
Details

When called, `recover` prints the list of current calls, and prompts the user to select one of them. The standard R `browser` is then invoked from the corresponding environment; the user can type ordinary R language expressions to be evaluated in that environment.

When finished browsing in this call, type `c` to return to `recover` from the browser. Type another frame number to browse some more, or type `p` to exit `recover`.

The use of `recover` largely supersedes `dump.frames` as an error option, unless you really want to wait to look at the error. If `recover` is called in non-interactive mode, it behaves like `dump.frames`. For computations involving large amounts of data, `recover` has the advantage that it does not need to copy out all the environments in order to browse in them. If you do decide to quit interactive debugging, call `dump.frames` directly while browsing in any frame (see the examples).

Value

Nothing useful is returned. However, you `can` invoke `recover` directly from a function, rather than through the error option shown in the examples. In this case, execution continues after you type `p` to exit `recover`.

Compatibility Note

The R `recover` function can be used in the same way as the S function of the same name; therefore, the error option shown is a compatible way to specify the error action. However, the actual functions are essentially unrelated and interact quite differently with the user. The navigating commands `up` and `down` do not exist in the R version; instead, exit the browser and select another frame.

References

John M. Chambers (1998). Programming with Data; Springer. See the compatibility note above, however.

See Also

`browser` for details about the interactive computations; `options` for setting the error option; `dump.frames` to save the current environments for later debugging.

Examples

```r
## Not run:

options(error = recover) # setting the error option

### Example of interaction

> myFit <- lm(y ~ x, data = xy, weights = w)
Error in lm.wfit(x, y, w, offset = offset, ...) :
  missing or negative weights not allowed

Enter a frame number, or 0 to exit
1:lm(y ~ x, data = xy, weights = w)
2:lm.wfit(x, y, w, offset = offset, ...) 
Selection: 2
Called from: eval(expr, envir, enclos)
Browse[1]> objects() # all the objects in this frame
[1] "method" "n" "ny" "offset" "tol" "w"
```
relist

### Allow Re-Listing an unlist()ed Object

**Description**

relist() is an S3 generic function with a few methods in order to allow easy inversion of unlist(obj) when that is used with an object obj of (S3) class "relistable".

**Usage**

```
relist(flesh, skeleton)
```

**Arguments**

- `flesh` a vector to be relisted
- `skeleton` a list, the structure of which determines the structure of the result
- `x` an R object, typically a list (or vector).
- `recursive` logical. Should unlisting be applied to list components of x?
- `use.names` logical. Should names be preserved?
Details

Some functions need many parameters, which are most easily represented in complex structures, e.g., nested lists. Unfortunately, many mathematical functions in R, including optim and nlm can only operate on functions whose domain is a vector. R has `unlist()` to convert nested list objects into a vector representation. `relist()`, its methods and the functionality mentioned here provide the inverse operation to convert vectors back to the convenient structural representation. This allows structured functions (such as `optim()`) to have simple mathematical interfaces.

For example, a likelihood function for a multivariate normal model needs a variance-covariance matrix and a mean vector. It would be most convenient to represent it as a list containing a vector and a matrix. A typical parameter might look like

```r
list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0))).
```

However, `optim` cannot operate on functions that take lists as input; it only likes numeric vectors. The solution is conversion. Given a function `mvdnorm(x, mean, vcov, log = FALSE)` which computes the required probability density, then

```r
ipar <- list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)

ll <- function(param.vector)
{
  param <- relist(param.vector, skeleton = ipar)
  -sum(mvdnorm(x, mean = param$mean, vcov = param$vcov, log = TRUE))
}

optim(unlist(initial.param), ll)
```

`relist` takes two parameters: skeleton and flesh. Skeleton is a sample object that has the right shape but the wrong content. Flesh is a vector with the right content but the wrong shape. Invoking

```r
relist(flesh, skeleton)
```

will put the content of flesh on the skeleton. You don’t need to specify skeleton explicitly if the skeleton is stored as an attribute inside flesh. In particular, if flesh was created from some object obj with `unlist(as.relistable(obj))` then the skeleton attribute is automatically set. (Note that this does not apply to the example here, as `optim` is creating a new vector to pass to `ll` and not its `par` argument.)

As long as skeleton has the right shape, it should be a precise inverse of `unlist`. These equalities hold:

```r
relist(unlist(x), x) == x
unlist(relist(y, skeleton)) == y
x <- as.relistable(x)
relist(unlist(x)) == x
```

Value

an object of (S3) class "relistable" (and "list").
Description

Utility for removing add-on packages.

Usage

R CMD REMOVE [options] [-l lib] pkgs

Arguments

pkgs  a space-separated list with the names of the packages to be removed.
lib   the path name of the R library tree to remove from. May be absolute or relative. Also accepted in the form ‘--library=lib’.
options further options for help or version.

Details

If used as R CMD REMOVE pkgs without explicitly specifying lib, packages are removed from the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To remove from the library tree lib instead of the default one, use R CMD REMOVE -l lib pkgs.

Use R CMD REMOVE --help for more usage information.

Note

Some binary distributions of R have REMOVE in a separate bundle, e.g. an R-devel RPM.

See Also

INSTALL, remove.packages
remove.packages  

Remove Installed Packages

Description

Removes installed packages/bundles and updates index information as necessary.

Usage

remove.packages(pkgs, lib)

Arguments

pkgs  a character vector with the names of the packages to be removed.
lib   a character vector giving the library directories to remove the packages from. If missing, defaults to the first element in .libPaths().

See Also

REMOVE for a command line version; install.packages for installing packages.

removeSource  

Remove Stored Source from a Function.

Description

When options("keep.source") is TRUE, a copy of the original source code to a function is stored with it. This function removes that copy.

Usage

removeSource(fn)

Arguments

fn      A single function from which to remove the source.

Details

This removes both the "source" attribute (from R version 2.13.x or earlier) and the "srceref" and related attributes.

Value

A copy of the function with the source removed.

See Also

srceref for a description of source reference records, deparse for a description of how functions are deparsed.
Examples

```r
fn <- function(x) {
  x + 1  # A comment, kept as part of the source
}
fn
fn <- removeSource(fn)
fn
```

---

**RHOME**

*R Home Directory*

**Description**

Returns the location of the R home directory, which is the root of the installed R tree.

**Usage**

```r
R RHOME
```

---

**roman**

*Roman Numerals*

**Description**

Manipulate integers as roman numerals.

**Usage**

```r
as.roman(x)
```

**Arguments**

- `x` a numeric vector, or a character vector of arabic or roman numerals.

**Details**

`as.roman` creates objects of class "roman" which are internally represented as integers, and have suitable methods for printing, formatting, subsetting, and coercion to character.

Only numbers between 1 and 3899 have a unique representation as roman numbers.

**References**

Rprof

Examples

```r
## First five roman 'numbers'.
(y <- as.roman(1:5))
## Middle one.
y[3]
## Current year as a roman number.
(y <- as.roman(format(Sys.Date(), "%Y")))
## 10 years ago ...
y - 10
```

Description

Enable or disable profiling of the execution of R expressions.

Usage

```r
Rprof(filename = "Rprof.out", append = FALSE, interval = 0.02,
memory.profiling = FALSE, gc.profiling = FALSE,
line.profiling = FALSE, numfiles = 100L, bufsize = 10000L)
```

Arguments

- `filename` The file to be used for recording the profiling results. Set to NULL or "" to disable profiling.
- `append` logical: should the file be over-written or appended to?
- `interval` real: time interval between samples.
- `memory.profiling` logical: write memory use information to the file?
- `gc.profiling` logical: record whether GC is running?
- `line.profiling` logical: write line locations to the file?
- `numfiles`, `bufsize` integers: line profiling memory allocation

Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling works by writing out the call stack every interval seconds, to the file specified. Either the `summaryRprof` function or the wrapper script `R CMD Rprof` can be used to process the output file to produce a summary of the usage; use `R CMD Rprof --help` for usage information.

How time is measured varies by platform: on a Unix-alike it is the CPU time of the R process, so for example excludes time when R is waiting for input or for processes run by `system` to return.

Note that the timing interval cannot usefully be too small: once the timer goes off, the information is not recorded until the next timing click (probably in the range 1–10msecs).

Functions will only be recorded in the profile log if they put a context on the call stack (see `sys.calls`). Some primitive functions do not do so: specifically those which are of type "special" (see the 'R Internals' manual for more details).
Individual statements will be recorded in the profile log if line.profiling is TRUE, and if the code being executed was parsed with source references. See `parse` for a discussion of source references. By default the statement locations are not shown in `summaryRprof`, but see that help page for options to enable the display.

**Note**

Profiling is not available on all platforms. By default, support for profiling is compiled in if possible – configure R with `--disable-R-profiling` to change this.

As R profiling uses the same mechanisms as C profiling, the two cannot be used together, so do not use `Rprof` in an executable built for C-level profiling.

**Note**

The profiler interrupts R asynchronously, and it cannot allocate memory to store results as it runs. This affects line profiling, which needs to store an unknown number of file pathnames. The `numFiles` and `bufsize` arguments control the size of pre-allocated buffers to hold these results: the former counts the maximum number of paths, the latter counts the numbers of bytes in them. If the profiler runs out of space it will skip recording the line information for new files, and issue a warning when `Rprof(NULL)` is called to finish profiling.

**See Also**

The chapter on “Tidying and profiling R code” in “Writing R Extensions” (see the `doc/manual` subdirectory of the R source tree).

`summaryRprof` to analyse the output file.

`tracemem`, `Rprofmem` for other ways to track memory use.

**Examples**

```r
Rprofmem
```

---

Rprofmem

**Enable Profiling of R’s Memory Use**

Description

Enable or disable reporting of memory allocation in R.

Usage

```r
Rprofmem(filename = "Rprofmem.out", append = FALSE, threshold = 0)
```
Arguments

filename The file to be used for recording the memory allocations. Set to NULL or "" to disable reporting.
append logical: should the file be over-written or appended to?
threshold numeric: allocations on R's "large vector" heap larger than this number of bytes will be reported.

Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling writes the call stack to the specified file every time malloc is called to allocate a large vector object or to allocate a page of memory for small objects. The size of a page of memory and the size above which malloc is used for vectors are compile-time constants, by default 2000 and 128 bytes respectively.

The profiler tracks allocations, some of which will be to previously used memory and will not increase the total memory use of R.

Value

None

Note

The memory profiler slows down R even when not in use, and so is a compile-time option. The memory profiler can be used at the same time as other R and C profilers.

See Also

The R sampling profiler, Rprof also collects memory information.

tracemem traces duplications of specific objects.

The "Writing R Extensions” manual section on "Tidying and profiling R code"

Examples

## Not run:
## not supported unless R is compiled to support it.
Rprofmem("Rprofmem.out", threshold = 1000)
example(glm)
Rprofmem(NULL)
noquote(readlines("Rprofmem.out", n = 5))

## End(Not run)
**Rscript**

*Scripting Front-End for R*

**Description**

This is an alternative front end for use in ‘#!’ scripts and other scripting applications.

**Usage**

```
Rscript [options] [-e expr [-e expr2 ...] | file] [args]
```

**Arguments**

- **options**: a list of options, all beginning with ‘--’. These can be any of the options of the standard R front-end, and also those described in the details.
- **expr, expr2**: R expression(s), properly quoted.
- **file**: the name of a file containing R commands. ‘-’ indicates ‘stdin’.
- **args**: arguments to be passed to the script in file.

**Details**

- `Rscript --help` gives details of usage, and `Rscript --version` gives the version of Rscript.
- Other invocations invoke the R front-end with selected options. This front-end is convenient for writing ‘#!’ scripts since it is an executable and takes file directly as an argument. Options ‘--slave --no-restore’ are always supplied: these imply ‘--no-save’. (The standard Windows command line has no concept of ‘#!’ scripts, but Cygwin shells do.)
- Either one or more ‘-e’ options or file should be supplied. When using ‘-e’ options be aware of the quoting rules in the shell used: see the examples.
- Additional options accepted (before file or args) are
  - ‘--verbose’ gives details of what Rscript is doing. Also passed on to R.
  - ‘--default-packages=list’ where list is a comma-separated list of package names or NULL.
    Sets the environment variable R_DEFAULT_PACKAGES which determines the packages loaded on startup. The default for Rscript omits methods as it takes about 60% of the startup time.
- Spaces are allowed in expression and file (but will need to be protected from the shell in use, if any, for example by enclosing the argument in quotes).
- Normally the version of R is determined at installation, but this can be overridden by setting the environment variable R_HOME.
- `stdin()` refers to the input file, and `file("stdin")` to the stdin file stream of the process.

**Note**

Rscript is only supported on systems with the execv system call.
Examples

```r
## Not run:
Rscript -e 'date()' -e 'format(Sys.time(), "%a %b %d %X %Y")'

## example #! script for a Unix-alike

#!/path/to/Rscript --vanilla --default-packages=utils
args <- commandArgs(TRUE)
res <- try(install.packages(args))
if(inherits(res, "try-error")) q(status=1) else q()

## End(Not run)
```

Description

Utility function to find and display R documentation.

Usage

```r
RShowDoc(what, type = c("pdf", "html", "txt"), package)
```

Arguments

- **what**: a character string: see ‘Details’.
- **type**: an optional character string giving the preferred format.
- **package**: an optional character string specifying the name of a package within which to look for documentation.

Details

what can specify one of several different sources of documentation, including the R manuals (R-admin, R-data, R-exts, R-intro, R-ints, R-lang), NEWS, COPYING (the GPL licence), any of the licenses in ‘share/licenses’, FAQ (also available as R-FAQ), and the files in ‘R_HOME/doc’.

Only on Windows, the R for Windows FAQ is specified by rw-FAQ.

If package is supplied, documentation is looked for in the ‘doc’ and top-level directories of an installed package of that name.

If what is missing a brief usage message is printed.

The documentation types are tried in turn starting with the first specified in type (or "pdf" if none is specified).

Value

A invisible character string given the path to the file found.
Examples

RSiteSearch("R-lang")
RSiteSearch("FAQ", type = "html")
RSiteSearch("frame", package = "grid")
RSiteSearch("changes.txt", package = "grid")
RSiteSearch("NEWS", package = "MASS")

RSiteSearch
Search for Key Words or Phrases in Documentation

Description

Search for key words or phrases in help pages, vignettes or task views, using the search engine at http://search.r-project.org and view them in a web browser.

Usage

RSiteSearch(string,
         restrict = c("functions", "vignettes", "views"),
         format = c("normal", "short"),
         sortby = c("score", "date:late", "date:early",
                     "subject", "subject:descending",
                     "from", "from:descending",
                     "size", "size:descending"),
         matchesPerPage = 20)

Arguments

string A character string specifying word(s) or a phrase to search. If the words are to
         be searched as one entity, enclose all words in braces (see the first example).
restrict a character vector, typically of length greater than one. Possible areas to search
         in: functions for help pages, views for task views and vignettes for package
         vignettes.
format normal or short (no excerpts); can be abbreviated.
sortby character string (can be abbreviated) indicating how to sort the search results:
         (score, date:late for sorting by date with latest results first, date:early for
         earliest first, subject for subject in alphabetical order, subject:descending
         for reverse alphabetical order, from or from:descending for sender (when
         applicable), size or size:descending for size.)
matchesPerPage How many items to show per page.

Details

This function is designed to work with the search site at http://search.r-project.org, and
depends on that site continuing to be made available (thanks to Jonathan Baron and the School of
Arts and Sciences of the University of Pennsylvania).

Unique partial matches will work for all arguments. Each new browser window will stay open
unless you close it.
rtags

An Etags-like Tagging Utility for R

Description

rtags provides etags-like indexing capabilities for R code, using R's own parser.

Usage

rtags(path = ".", pattern = "\.[RrSs]$", recursive = FALSE,
      src = list.files(path = path, pattern = pattern,
                       full.names = TRUE,
                       recursive = recursive),
      keep.re = NULL,
      ofile = "", append = FALSE,
      verbose = gotOption("verbose"))

Arguments

path, pattern, recursive

Arguments passed on to list.files to determine the files to be tagged. By default, these are all files with extension .R, .r, .S, and .s in the current directory. These arguments are ignored if src is specified.

src

A vector of file names to be indexed.

keep.re

A regular expression further restricting src (the files to be indexed). For example, specifying keep.re = "/R/[^/]*\./\R$" will only retain files with extension .R inside a directory named R.

Value

(Invisibly) the complete URL passed to the browser, including the query string.

Author(s)

Andy Liaw and Jonathan Baron

See Also

help.search, help.start for local searches.
browseURL for how the help file is displayed.

Examples

# need Internet connection
RSiteSearch("(logistic regression)")  # matches exact phrase
Sys.sleep(5)  # allow browser to open, take a quick look
## Search in vignettes and store the query-string:
fullquery <- RSiteSearch("lattice", restrict = "vignettes")
fullquery  # a string of ~ 110 characters
ofile
Passed on to cat as the file argument; typically the output file where the tags will be written ("TAGS" by convention). By default, the output is written to the R console (unless redirected).

append
Logical, indicating whether the output should overwrite an existing file, or append to it.

verbose
Logical. If TRUE, file names are echoed to the R console as they are processed.

Details
Many text editors allow definitions of functions and other language objects to be quickly and easily located in source files through a tagging utility. This functionality requires the relevant source files to be preprocessed, producing an index (or tag) file containing the names and their corresponding locations. There are multiple tag file formats, the most popular being the vi-style ctags format and the and emacs-style etags format. Tag files in these formats are usually generated by the ctags and etags utilities respectively. Unfortunately, these programs do not recognize R code syntax. They do allow tagging of arbitrary language files through regular expressions, but this too is insufficient.

The rtags function is intended to be a tagging utility for R code. It parses R code files (using R’s parser) and produces tags in Emacs’ etags format. Support for vi-style tags is currently absent, but should not be difficult to add.

Examples
## Not run:
rtags("/path/to/src/repository",
    pattern = ".]*\.[RrSs]$",
    keep.re = "/R/",
    verbose = TRUE,
    ofile = "TAGS",
    append = FALSE,
    recursive = TRUE)

## End(Not run)
Rtangle

R Driver for Stangle

Description

A driver for Stangle that extracts R code chunks.

Usage

Rtangle()
RtangleSetup(file, syntax, output = NULL, annotate = TRUE,
      split = FALSE, quiet = FALSE, ...)

Arguments

file  Name of Sweave source file. See the description of the corresponding argument
      of Sweave.
syntax An object of class SweaveSyntax.
output Name of output file used unless split = TRUE: see ‘Details’.
annotate By default, code chunks are separated by comment lines specifying the names
       and numbers of the code chunks. If FALSE the decorating comments are omitted.
split  Split output into a file for each code chunk?
quiet  If TRUE all progress messages are suppressed.
...   Additional named arguments setting defaults for further options.

Details

Unless split = TRUE, the default name of the output file is basename(file) with an extension
      corresponding to the Sweave syntax (e.g., ‘Rnw’, ‘Stex’) replaced by ‘R’. File names
      ‘stdout’ and ‘stderr’ are interpreted as the output and message connection respectively.
If splitting is selected (including by the options in the file), each chunk is written to a separate file
      with extension the name of the ‘engine’ (default `.R`).
The annotation is of one of the forms

`##########################################`
`### code chunk number 3: viewport`
`##########################################`

`##########################################`
`### code chunk number 18: grid.Rnw:647-648`
`##########################################`

`##########################################`
`### code chunk number 19: trellisdata (eval = FALSE)`
`##########################################`

using either the chunk label or the file name and line numbers.

Note that this driver does not simple extract the code chunks verbatim because code chunks can
re-use earlier chunks.
Supported Options

Rtangle supports the following options for code chunks (the values in parentheses show the default values):

- **engine**: character string ("R"). Only chunks with engine equal to "R" or "S" are processed.
- **keep.source**: logical (TRUE). If keep.source == TRUE the original source is copied to the file. Otherwise, deparsed source is output.
- **eval**: logical (TRUE). If FALSE, the code chunk is copied across but commented out.
- **prefix** Used if split = TRUE. See prefix.string.
- **prefix.string**: a character string, default is the name of the source file (without extension). Used if split = TRUE as the prefix for the filename if the chunk has no label, or if it has a label and prefix = TRUE. Note that this is used as part of filenames, so needs to be portable.
- **show.line.nos** logical (FALSE). Should the output be annotated with comments showing the line number of the first code line of the chunk?

Author(s)

Friedrich Leisch and R-core.

Sweave, *RweaveLatex*

---

**RweaveLatex**  
*R/\LaTeX\ Driver for Sweave*

Description

A driver for Sweave that translates R code chunks in LaTeX files.

Usage

RweaveLatex()

RweaveLatexSetup(file, syntax, output = NULL, quiet = FALSE,  
        debug = FALSE, stylepath, ...)

Arguments

- **file**: Name of Sweave source file. See the description of the corresponding argument of Sweave.
- **syntax**: An object of class SweaveSyntax.
- **output**: Name of output file. The default is to remove extension '.nw', '.Rnw' or '.Snw' and to add extension '.tex'. Any directory paths in file are also removed such that the output is created in the current working directory.
- **quiet**: If TRUE all progress messages are suppressed.
- **debug**: If TRUE, input and output of all code chunks is copied to the console.
- **stylepath**: See 'Details'.
- **...**: named values for the options listed in 'Supported Options'.
Details

The LaTeX file generated needs to contain the line `\usepackage{Sweave}`, and if this is not present in the Sweave source file (possibly in a comment), it is inserted by the RweaveLatex driver. If `stylepath = TRUE`, a hard-coded path to the file `Sweave.sty` in the R installation is set in place of Sweave. The hard-coded path makes the LaTeX file less portable, but avoids the problem of installing the current version of `Sweave.sty` to some place in your TeX input path. However, TeX may not be able to process the hard-coded path if it contains spaces (as it often will under Windows) or TeX special characters.

The default for `stylepath` is now taken from the environment variable `SWEAVE_STYLEPATH_DEFAULT`, or is `FALSE` it that is unset or empty. If set, it should be exactly `TRUE` or `FALSE`; any other values are taken as `FALSE`.

The simplest way for frequent Sweave users to ensure that `Sweave.sty` is in the TeX input path is to add `R_HOME/share/texmf` as a `texmf tree` (‘root directory’ in the parlance of the ‘MiKTeX settings’ utility).

By default, `Sweave.sty` sets the width of all included graphics to:
`\setkeys{gin}{width=0.8\textwidth}'.

This setting affects the width size option passed to the `\includegraphics{}` directive for each plot file and in turn impacts the scaling of your plot files as they will appear in your final document.

Thus, for example, you may set `width=3` in your figure chunk and the generated graphics files will be set to 3 inches in width. However, the width of your graphic in your final document will be set to `0.8\textwidth` and the height dimension will be scaled accordingly. Fonts and symbols will be similarly scaled in the final document.

You can adjust the default value by including the `\setkeys{gin}{width=...}' directive in your `.Rnw` file after the `\begin{document}' directive and changing the width option value as you prefer, using standard LaTeX measurement values.

If you wish to override this default behavior entirely, you can add a `\usepackage[nogin]{Sweave}' directive in your preamble. In this case, no size/scaling options will be passed to the `\includegraphics{}` directive and the height and width options will determine both the runtime generated graphic file sizes and the size of the graphics in your final document.

`Sweave.sty` also supports the `[noae]` option, which suppresses the use of the ‘ae’ package, the use of which may interfere with certain encoding and typeface selections. If you have problems in the rendering of certain character sets, try this option.

As from R 3.1.0 it also supports the `[inconsolata]` option, to render monospaced text in inconsolata, the font used by default for R help pages.

The use of fancy quotes (see `sQuote`) can cause problems when setting R output. Either set `options(useFancyQuotes = FALSE)` or arrange that LaTeX is aware of the encoding used (by a `\usepackage[utf8]{inputenc}' declaration: Windows users of Sweave from RGui.exe will need to replace ‘utf8’ by ‘cp1252’ or similar) and ensure that typewriter fonts containing directional quotes are used.

Some LaTeX graphics drivers do not include ‘.png’ or ‘.jpg’ in the list of known extensions. To enable them, add something like `\DeclareGraphicsExtensions{.png,.pdf,.jpg}' to the preamble of your document or check the behavior of your graphics driver. When both pdf and png are `TRUE` both files will be produced by Sweave, and their order in the `\DeclareGraphicsExtensions` list determines which will be used by pdflatex.
**Supported Options**

RweaveLaTeX supports the following options for code chunks (the values in parentheses show the default values). Character string values should be quoted when passed from Sweave through ... but not when use in the header of a code chunk.

**engine**: character string ("R"). Only chunks with engine equal to "R" or "S" are processed.

**echo**: logical (TRUE). Include R code in the output file?

**keep.source**: logical (TRUE). When echoing, if keep. source == TRUE the original source is copied to the file. Otherwise, deparsed source is echoed.

**eval**: logical (TRUE). If FALSE, the code chunk is not evaluated, and hence no text nor graphical output produced.

**results**: character string ("verbatim"). If "verbatim", the output of R commands is included in the verbatim-like 'soutput' environment. If "tex", the output is taken to be already proper LaTeX markup and included as is. If "hide" then all output is completely suppressed (but the code executed during the weave).

**print**: logical (FALSE). If TRUE, this forces auto-printing of all expressions.

**term**: logical (TRUE). If TRUE, visibility of values emulates an interactive R session: values of assignments are not printed, values of single objects are printed. If FALSE, output comes only from explicit print or similar statements.

**split**: logical (FALSE). If TRUE, text output is written to separate files for each code chunk.

**strip.white**: character string ("true"). If "true", blank lines at the beginning and end of output are removed. If "all", then all blank lines are removed from the output. If "false" then blank lines are retained.

A 'blank line' is one that is empty or includes only whitespace (spaces and tabs).

Note that blank lines in a code chunk will usually produce a prompt string rather than a blank line on output.

**prefix**: logical (TRUE). If TRUE generated filenames of figures and output all have the common prefix given by the prefix.string option: otherwise only unlabelled chunks use the prefix.

**prefix.string**: a character string, default is the name of the source file (without extension). Note that this is used as part of filenames, so needs to be portable.

**include**: logical (TRUE), indicating whether input statements for text output (if split = TRUE) and 'includegraphics' statements for figures should be auto-generated. Use include = FALSE if the output should appear in a different place than the code chunk (by placing the input line manually).

**fig**: logical (FALSE), indicating whether the code chunk produces graphical output. Note that only one figure per code chunk can be processed this way. The labels for figure chunks are used as part of the file names, so should preferably be alphanumeric.

**eps**: logical (FALSE), indicating whether EPS figures should be generated. Ignored if fig = FALSE.

**pdf**: logical (TRUE), indicating whether PDF figures should be generated. Ignored if fig = FALSE.

**pdf version**, **pdf.encoding**, **pdf.compress**: passed to pdf to set the version, encoding and compression (or not). Defaults taken from pdf.options().

**png**: logical (FALSE), indicating whether PNG figures should be generated. Ignored if fig = FALSE. Only available in R >= 2.13.0.

**jpeg**: logical (FALSE), indicating whether JPEG figures should be generated. Ignored if fig = FALSE. Only available in R >= 2.13.0.

**grdevice**: character (NULL): see section ‘Custom Graphics Devices’. Ignored if fig = FALSE. Only available in R >= 2.13.0.
width: numeric (6), width of figures in inches. See ‘Details’.

height: numeric (6), height of figures in inches. See ‘Details’.

resolution: numeric (300), resolution in pixels per inch: used for PNG and JPEG graphics. Note that the default is a fairly high value, appropriate for high-quality plots. Something like 100 is a better choice for package vignettes.

concordance: logical (FALSE). Write a concordance file to link the input line numbers to the output line numbers. This is an experimental feature; see the source code for the output format, which is subject to change in future releases.

figs.only: logical (FALSE). By default each figure chunk is run once, then re-run for each selected type of graphics. That will open a default graphics device for the first figure chunk and use that device for the first evaluation of all subsequent chunks. If this option is true, the figure chunk is run only for each selected type of graphics, for which a new graphics device is opened and then closed.

In addition, users can specify further options, either in the header of an individual code section or in a ‘\SweaveOpts{...}’ line in the document. For unknown options, their type is set at first use.

Custom Graphics Devices

If option grdevice is supplied for a code chunk with both fig and eval true, the following call is made

```r
get(options$grdevice, envir = .GlobalEnv)(name=, width=,
  height=, options)
```

which should open a graphics device. The chunk’s code is then evaluated and `dev.off` is called. Normally a function of the name given will have been defined earlier in the Sweave document, e.g.

```
<<results=hide>>=
my.Swd <- function(name, width, height, ...)
  grDevices::png(filename = paste(name, "png", sep = "."),
    width = width, height = height, res = 100,
    units = "in", type = "quartz", bg = "transparent")
@
```

Currently only one custom device can be used for each chunk, but different devices can be used for different chunks.

A replacement for `dev.off` can be provided as a function with suffix `.off`, e.g. `my.Swd.off()`.

Hook Functions

Before each code chunk is evaluated, zero or more hook functions can be executed. If `getOption("SweaveHooks")` is set, it is taken to be a named list of hook functions. For each logical option of a code chunk (echo, print, ...) a hook can be specified, which is executed if and only if the respective option is TRUE. Hooks must be named elements of the list returned by `getOption("SweaveHooks")` and be functions taking no arguments. E.g., if option "SweaveHooks" is defined as `list(fig = foo)`, and `foo` is a function, then it would be executed before the code in each figure chunk. This is especially useful to set defaults for the graphical parameters in a series of figure chunks.

Note that the user is free to define new Sweave logical options and associate arbitrary hooks with them. E.g., one could define a hook function for a new option called `clean` that removes all objects in the workspace. Then all code chunks specified with `clean = TRUE` would start operating on an empty workspace.
savehistory

Author(s)

Friedrich Leisch and R-core

See Also

'Sweave User Manual', a vignette in the utils package.

Sweave, Rtag

Description

Load or save or display the commands history.

Usage

loadhistory(file = ".Rhistory")
savehistory(file = ".Rhistory")

history(max.show = 25, reverse = FALSE, pattern, ...)

timestamp(stamp = date(),
  prefix = "##----- ", suffix = " ------##",
  quiet = FALSE)

Arguments

file The name of the file in which to save the history, or from which to load it. The path is relative to the current working directory.

max.show The maximum number of lines to show. Inf will give all of the currently available history.

reverse logical. If true, the lines are shown in reverse order. Note: this is not useful when there are continuation lines.

pattern A character string to be matched against the lines of the history. When supplied, only unique matching lines are shown.

... Arguments to be passed to grep when doing the matching.

stamp A value or vector of values to be written into the history.

prefix A prefix to apply to each line.

suffix A suffix to apply to each line.

quiet If TRUE, suppress printing timestamp to the console.
select.list 1871

Details

There are several history mechanisms available for the different R consoles, which work in similar but not identical ways. There are separate versions of this help file for Unix and Windows.

The functions described here work on Unix-alikes under the readline command-line interface but may not otherwise (for example, in batch use or in an embedded application). Note that R can be built without readline.

R.app, the console on OS X, has a separate and largely incompatible history mechanism, which by default uses a file ‘.Rapp.history’ and saves up to 250 entries. These functions are not currently implemented there.

The readline history mechanism is controlled by two environment variables: R_HISTSIZE controls the number of lines that are saved (default 512), and R_HISTFILE (default ‘.Rhistory’) sets the filename used for the loading/saving of history if requested at the beginning/end of a session (but not the default for loadhistory/savehistory). There is no limit on the number of lines of history retained during a session, so setting R_HISTSIZE to a large value has no penalty unless a large file is actually generated.

These environment variables are read at the time of saving, so can be altered within a session by the use of Sys.setenv.

Note that readline history library saves files with permission 0600, that is with read/write permission for the user and not even read permission for any other account.

The timestamp function writes a timestamp (or other message) into the history and echos it to the console. On platforms that do not support a history mechanism only the console message is printed.

Note

If you want to save the history at the end of (almost) every interactive session (even those in which you do not save the workspace), you can put a call to savehistory() in .Last. See the examples.

Examples

```r
## Not run:
## Save the history in the home directory: note that it is not
## (by default) read from there but from the current directory
>Last <- function()
  if(interactive()) try(savehistory("~/Rhistory"))

## End(Not run)
```

select.list  Select Items from a List

Description

Select item(s) from a character vector.

Usage

```r
select.list(choices, preselect = NULL, multiple = FALSE,
           title = NULL, graphics =getOption("menu.graphics"))
```
Arguments

- **choices**: a character vector of items.
- **preselect**: a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially.
- **multiple**: logical: can more than one item be selected?
- **title**: optional character string for window title, or NULL for no title.
- **graphics**: logical: should a graphical widget be used?

Details

The normal default is `graphics = TRUE`. Under the OS X GUI this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse. On other Unix-like platforms it will use a Tcl/Tk listbox widget if possible.

If `graphics` is `FALSE` or no graphical widget is available it displays a text list from which the user can choose by number(s). The `multiple` = `FALSE` case uses `menu`. Preselection is only supported for `multiple` = `TRUE`, where it is indicated by a "+" preceding the item.

It is an error to use `select.list` in a non-interactive session.

Value

A character vector of selected items. If `multiple` is `false` and no item was selected (or Cancel was used), "" is returned. If `multiple` is `true` and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

See Also

- `menu`, `tk_select.list` for a graphical version using Tcl/Tk.

Examples

```
## Not run:
select.list(sort(.packages(all.available = TRUE)))

## End(Not run)
```

---

**sessionInfo**

Collect Information About the Current R Session

Description

Print version information about R, the OS and attached or loaded packages.

Usage

```
sessionInfo(package = NULL)
```

## S3 method for class 'sessionInfo'

```
print(x, locale = TRUE,)
```

## S3 method for class 'sessionInfo'

toLatex(object, locale = TRUE, ...)
sessionInfo

Arguments

package a character vector naming installed packages, or NULL (the default) meaning all attached packages.

x an object of class "sessionInfo".

object an object of class "sessionInfo".

locale show locale information?

... currently not used.

Value

An object of class "sessionInfo", which has a print method. This is a list with components

R.version a list, the result of calling R.Version().

platform a character string describing the platform. Where sub-architectures are in use this is of the form ‘platform/sub-arch (nn-bit)’.

running a character string describing the OS and version which it is running under (as distinct from compiled under).

locale a character string, the result of calling Sys.getlocale().

basePkgs a character vector of base packages which are attached.

otherPkgs (not always present): a character vector of other attached packages.

loadedOnly (not always present): a named list of the results of calling packageDescription on packages whose namespaces are loaded but are not attached.

Note

The information on 'loaded' packages and namespaces is the current version installed at the location the package was loaded from: it can be wrong if another process has been changing packages during the session.

How OSes identify themselves and their versions can be arcane: where possible running uses a human-readable form.

See Also

R.version

Examples

sessionInfo()
toLatex(sessionInfo(), locale = FALSE)
Description

Interact with the user to choose the package repositories to be used.

Usage

```r
setRepositories(graphics = getOption("menu.graphics"),
    ind = NULL, addURLs = character())
```

Arguments

- `graphics` Logical. If true, use a graphical list: on Windows or OS X GUI use a list box, and on a Unix-alike if `tcltk` and an X server are available, use Tk widget. Otherwise use a text menu.
- `ind` NULL or a vector of integer indices, which have the same effect as if they were entered at the prompt for `graphics = FALSE`.
- `addURLs` A character vector of additional URLs: it is often helpful to use a named vector.

Details

The default list of known repositories is stored in the file `R_HOME/etc/repositories`. That file can be edited for a site, or a user can have a personal copy in `HOME/.R/repositories` which will take precedence.

A Bioconductor mirror can be selected by setting `options("BioC_mirror")`, e.g. via `chooseBioCmirror` the default value is “http://www.bioconductor.org”.

The items that are preselected are those that are currently in `options("repos")` plus those marked as default in the list of known repositories.

The list of repositories offered depends on the setting of option "pkgType" as some repositories only offer a subset of types (e.g., only source packages or not OS X binary packages). Further, for binary packages some repositories (notably R-Forge) only offer packages for the current or recent versions of R. (Type "both" is equivalent to "source".)

Repository ‘CRAN’ is treated specially: the value is taken from the current setting of `getOption("repos")` if this has an element "CRAN": this ensures mirror selection is sticky.

This function requires the R session to be interactive unless `ind` is supplied.

Value

This function is invoked mainly for its side effect of updating `options("repos")`. It returns (invisibly) the previous `repos` options setting (as a list with component `repos`) or `NULL` if no changes were applied.

Note

This does not set the list of repositories at startup: to do so set `options(repos =)` in a start up file (see help topic Startup).
See Also

chooseCRANmirror, chooseBioCmirror, install.packages.

Examples

```r
## Not run:
setRepositories(addURLs =
  c(CRANxtras = "http://www.stats.ox.ac.uk/pub/RWin"))

## End(Not run)
```

Description

Compile the given source files and then link all specified object files into a shared object aka DLL which can be loaded into R using dyn.load or library.dynam.

Usage

```
R CMD SHLIB [options] [-o dllname] files
```

Arguments

- **files**
  
a list specifying the object files to be included in the shared object/DLL. You can also include the name of source files (for which the object files are automagically made from their sources) and library linking commands.

- **dllname**
  
the full name of the shared object/DLL to be built, including the extension (typically `.so` on Unix systems, and `.dll` on Windows). If not given, the basename of the object/DLL is taken from the basename of the first file.

- **options**
  
Further options to control the processing. Use `R CMD SHLIB --help` for a current list.

Details

`R CMD SHLIB` is the mechanism used by `INSTALL` to compile source code in packages. It will generate suitable compilation commands for C, C++, Objective C(++) and Fortran sources: Fortran 90/95 sources can also be used but it may not be possible to mix these with other languages (on most platforms it is possible to mix with C, but mixing with C++ rarely works).

Please consult section ‘Creating shared objects’ in the manual ‘Writing R Extensions’ for how to customize it (for example to add `cpp` flags and to add libraries to the link step) and for details of some of its quirks.

Items in `files` with extensions `.c`, `.cpp`, `.cc`, `.C`, `.f`, `.f90`, `.f95`, `.m` (ObjC), `.M` and `.mm` (ObjC++) are regarded as source files, and those with extension `.o` as object files. All other items are passed to the linker.

Objective C(++) support is optional when R was configured: their main usage is on OS X.

Note that the appropriate run-time libraries will be used when linking if C++, Fortran or Objective C(++) sources are supplied, but not for compiled object files from these languages.

Option `-n` (also known as ‘--dry-run’) will show the commands that would be run without actually executing them.
Note
Some binary distributions of R have SHLIB in a separate bundle, e.g., an R-devel RPM.

See Also
COMPILER, dyn.load, library.dynam.
The ‘R Installation and Administration’ and ‘Writing R Extensions’ manuals, including the section on “Customizing compilation” in the former.

Examples
## Not run:
# To link against a library not on the system library paths:
R CMD SHLIB -o mylib.so a.f b.f -L/opt/acml3.5.0-gnu64/lib -lacml

## End(Not run)

sourceutils Source Reference Utilities

Description
These functions extract information from source references.

Usage
getSrcFilename(x, full.names = FALSE, unique = TRUE)
getSrcDirectory(x, unique = TRUE)
getSrcRef(x)
getSrcLocation(x, which = c("line", "column", "byte", "parse"),
     first = TRUE)

Arguments
x An object (typically a function) containing source references.
full.names Whether to include the full path in the filename result.
unique Whether to list only unique filenames/directories.
which Which part of a source reference to extract.
first Whether to show the first (or last) location of the object.

Details
Each statement of a function will have its own source reference if the "keep.source" option is TRUE. These functions retrieve all of them.
The components are as follows:

line The line number where the object starts or ends.
column The column number where the object starts or ends.
byte As for "column", but counting bytes, which may differ in case of multibyte characters.
parse As for "line", but this ignores #line directives.
Value

getSrcFilename and getSrcDirectory return character vectors holding the filename/directory.
getSrcRef returns a list of `SrcRef` objects or NULL if there are none.
getSrcLocation returns an integer vector of the requested type of locations.

See Also

`srcRef`, `getParsedData`

Examples

```r
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}

# Show the temporary file directory
# where the example was saved
getSrcDirectory(fn)
getSrcLocation(fn, "line")
```

---

**stack**

Stack or Unstack Vectors from a Data Frame or List

Description

Stacking vectors concatenates multiple vectors into a single vector along with a factor indicating where each observation originated. Unstacking reverses this operation.

Usage

```r
stack(x, ...)  # Default S3 method
stack(x, ...)  # S3 method for class 'data.frame'
stack(x, select, ...)
unstack(x, ...)  # Default S3 method
unstack(x, form, ...)  # S3 method for class 'data.frame'
unstack(x, form, ...)
```

Arguments

- `x` a list or data frame to be stacked or unstacked.
- `select` an expression, indicating which variable(s) to select from a data frame.
- `form` a two-sided formula whose left side evaluates to the vector to be unstacked and whose right side evaluates to the indicator of the groups to create. Defaults to `formula(x)` in the data frame method for unstack.
- `...` further arguments passed to or from other methods.
Details

The `stack` function is used to transform data available as separate columns in a data frame or list into a single column that can be used in an analysis of variance model or other linear model. The `unstack` function reverses this operation.

Note that `stack` applies to vectors (as determined by `is.vector`): non-vector columns (e.g., factors) will be ignored (with a warning as from R 2.15.0). Where vectors of different types are selected they are concatenated by `unlist` whose help page explains how the type of the result is chosen.

These functions are generic: the supplied methods handle data frames and objects coercible to lists by `as.list`.

Value

`unstack` produces a list of columns according to the formula `form`. If all the columns have the same length, the resulting list is coerced to a data frame.

`stack` produces a data frame with two columns:

- `values`: the result of concatenating the selected vectors in `x`.
- `ind`: a factor indicating from which vector in `x` the observation originated.

Author(s)

Douglas Bates

`lm, reshape`

Examples

```r
require(stats)
formula(PlantGrowth) # check the default formula
pg <- unstack(PlantGrowth) # unstack according to this formula
pg
stack(pg) # now put it back together
stack(pg, select = -ctrl) # omitting one vector
```

Description

`str` is a compactly display the structure of an arbitrary R object, a diagnostic function and an alternative to `summary` (and to some extent, `dput`). Ideally, only one line for each ‘basic’ structure is displayed. It is especially well suited to compactly display the (abbreviated) contents of (possibly nested) lists. The idea is to give reasonable output for any R object. It calls `args` for (non-primitive) function objects.

`strOptions()` is a convenience function for setting `options(str = .)`, see the examples.
Usage

str(object, ...)

## S3 method for class 'data.frame'
str(object, ...)

## Default S3 method:
str(object, max.level = NA,
vec.len = str0$vec.len, digits.d = str0$digits.d,
nchar.max = 128, give.attr = TRUE,
give.head = TRUE, give.length = give.head,
width = getOption("width"), nest.lev = 0,
indent.str = paste(rep.int(" ", max(0, nest.lev + 1)),
collapse = ".."),
comp.str = "$ ", no.list = FALSE, envir = baseenv(),
strict.width = str0$strict.width,
formatNum = str0$formatNum, list.len = 99, ...)

strOptions(strict.width = "no", digits.d = 3, vec.len = 4,
formatNum = function(x, ...)
format(x, trim = TRUE, dropTrailing = TRUE, ...))

Arguments

object any R object about which you want to have some information.
max.level maximal level of nesting which is applied for displaying nested structures, e.g.,
a list containing sub lists. Default NA: Display all nesting levels.
vec.len numeric (>= 0) indicating how many ‘first few’ elements are displayed of each
vector. The number is multiplied by different factors (from .5 to 3) depending
on the kind of vector. Defaults to the vec.len component of option "str" (see
options) which defaults to 4.
digits.d number of digits for numerical components (as for print). Defaults to the
digits.d component of option "str" which defaults to 3.
nchar.max maximal number of characters to show for character strings. Longer strings
are truncated, see longch example below.
give.attr logical; if TRUE (default), show attributes as sub structures.
give.length logical; if TRUE (default), indicate length (as [1:...]).
give.head logical; if TRUE (default), give (possibly abbreviated) mode/class and length (as
<type>[1:...]).
width the page width to be used. The default is the currently active
options("width"); note that this has only a weak effect, unless strict.width
is not "no".
nest.lev current nesting level in the recursive calls to str.
indent.str the indentation string to use.
comp.str string to be used for separating list components.
no.list logical; if true, no 'list of . . .' nor the class are printed.
envir the environment to be used for promise (see delayedAssign) objects only.
strict.width string indicating if the width argument’s specification should be followed strictly, one of the values c("no", "cut", "wrap"). Defaults to the strict.width component of option "str" (see options) which defaults to "no" for back compatibility reasons; "wrap" uses strwrap(*, width = width) whereas "cut" cuts directly to width. Note that a small vec.length may be better than setting strict.width = "wrap".

formatNum a function such as format for formatting numeric vectors. It defaults to the formatNum component of option "str", see “Usage” of strOptions() above, which is almost back compatible to R <= 2.7.x, however, using formatC may be slightly better.

list.len numeric; maximum number of list elements to display within a level.

... potential further arguments (required for Method/Generic reasons).

Value

str does not return anything, for efficiency reasons. The obvious side effect is output to the terminal.

Author(s)

Martin Maechler <maechler@stat.math.ethz.ch> since 1990.

See Also

ls.str for listing objects with their structure; summary, args.

Examples

str(freeqy)
str(str)
str(.Machine, digits.d = 20) # extra digits for identification of binary numbers
str(1sfit(1:9, 1:9))
str(1sfit(1:9, 1:9), max.level = 1)
str(1sfit(1:9, 1:9), width = 60, strict.width = "cut")
str(1sfit(1:9, 1:9), width = 60, strict.width = "wrap")
op <- options(); str(op)  # save first;
    # otherwise internal options() is used.
need.dev <-
    !exists(".Device") || is.null(.Device) || .Device == "null device"
    if(need.dev) postscript()
        str(par())
    if(need.dev) graphics.off()
} ch <- letters[1:12]; is.na(ch) <- 3:5
str(ch) # character NA's

str(list(a = "X", L = as.list(1:100)), list.len = 9)
nchar(longch <- paste(rep(letters,100), collapse = ""))
str(longch)
str(longch, nchar.max = 52)
summaryRprof

Summarise Output of R Sampling Profiler

Description
Summarise the output of the Rprof function to show the amount of time used by different R functions.

Usage
summaryRprof(filename = "Rprof.out", chunksize = 5000, memory = c("none", "both", "tseries", "stats"), lines = c("hide", "show", "both"), index = 2, diff = TRUE, exclude = NULL, basenames = 1)

Arguments
filename Name of a file produced by Rprof().
chunksize Number of lines to read at a time.
memory Summaries for memory information. See ‘Memory profiling’ below.
lines Summaries for line information. See ‘Line profiling’ below.
index How to summarize the stack trace for memory information. See ‘Details’ below.
diff If TRUE memory summaries use change in memory rather than current memory.
exclude Functions to exclude when summarizing the stack trace for memory summaries.
basenames Number of components of the path to filenames to display.
Details

This function provides the analysis code for `Rprof` files used by `R CMD Rprof`.

As the profiling output file could be larger than available memory, it is read in blocks of `chunksize` lines. Increasing `chunksize` will make the function run faster if sufficient memory is available.

Value

If `memory = "none"` and `lines = "hide"`, a list with components

- `by.self`: A data frame of timings sorted by ‘self’ time.
- `by.total`: A data frame of timings sorted by ‘total’ time.
- `sample.interval`: The sampling interval.
- `sampling.time`: Total time of profiling run.

The first two components have columns ‘self.time’, ‘self.pct’, ‘total.time’ and ‘total.pct’, the times in seconds and percentages of the total time spent executing code in that function and code in that function or called from that function, respectively.

If `lines = "show"`, an additional component is added to the list:

- `by.line`: A data frame of timings sorted by source location.

If `memory = "both"` the same list but with memory consumption in Mb in addition to the timings.

If `memory = "tseries"` a data frame giving memory statistics over time.

If `memory = "stats"` a `by` object giving memory statistics by function.

Prior to R 2.15.3 an error was thrown if no events were recorded: now zero-row data frames are returned.

Memory profiling

Options other than `memory = "none"` apply only to files produced by `Rprof(memory.profiling = TRUE)`.

When called with `memory.profiling = TRUE`, the profiler writes information on three aspects of memory use: vector memory in small blocks on the R heap, vector memory in large blocks (from `malloc`), memory in nodes on the R heap. It also records the number of calls to the internal function `duplicate` in the time interval. `duplicate` is called by C code when arguments need to be copied. Note that the profiler does not track which function actually allocated the memory.

With `memory = "both"` the change in total memory (truncated at zero) is reported in addition to timing data.

With `memory = "tseries"` or `memory = "stats"` the index argument specifies how to summarize the stack trace. A positive number specifies that many calls from the bottom of the stack; a negative number specifies the number of calls from the top of the stack. With `memory = "tseries"` the index is used to construct labels and may be a vector to give multiple sets of labels. With `memory = "stats"` the index must be a single number and specifies how to aggregate the data to the maximum and average of the memory statistics. With both `memory = "tseries"` and `memory = "stats"` the argument `diff = TRUE` asks for summaries of the increase in memory use over the sampling interval and `diff = FALSE` asks for the memory use at the end of the interval.
Line profiling

If the code being run has source reference information retained (via keep.source = TRUE in
source or KeepSource = TRUE in a package 'DESCRIPTION' file or some other way), then inform-
ation about the origin of lines is recorded during profiling. By default this is not displayed, but
the lines parameter can enable the display.

If lines = "show", line locations will be used in preference to the usual function name information,
and the results will be displayed ordered by location in addition to the other orderings.

If lines = "both", line locations will be mixed with function names in a combined display.

See Also

subdirectory of the R source tree).

Rprof

tracemem traces copying of an object via the C function duplicate.

Rprofmem is a non-sampling memory-use profiler.

http://developer.r-project.org/memory-profiling.html

Examples

## Not run:
## Rprof() is not available on all platforms
Rprof(tmp <- tempfile())
examp(gep)
Rprof()
summaryRprof(tmp)
unlink(tmp)

## End(Not run)

---

Sweave  Automatic Generation of Reports

Description

Sweave provides a flexible framework for mixing text and R/S code for automatic report generation.
The basic idea is to replace the code with its output, such that the final document only contains the
text and the output of the statistical analysis: however, the source code can also be included.

Usage

Sweave(file, driver = RweaveLaTeX(),
        syntax = getOption("SweaveSyntax"), encoding = "", ...)

Stangle(file, driver = Rstangle(),
         syntax = getOption("SweaveSyntax"), encoding = "", ...)
Arguments

- **file**: Path to Sweave source file. Note that this can be supplied without the extension, but the function will only proceed if there is exactly one Sweave file in the directory whose basename matches `file`.
- **driver**: The actual workhorse, see ‘Details’.
- **syntax**: NULL or an object of class `SweaveSyntax` or a character string with its name. See the section ‘Syntax Definition’.
- **encoding**: The default encoding to assume for `file`.
- ... Further arguments passed to the driver’s setup function: see section ‘Drivers’, `RweaveLatex` and `Rtangle`.

Details

Automatic generation of reports by mixing word processing markup (like LaTeX) and S code. The S code gets replaced by its output (text or graphs) in the final markup file. This allows a report to be re-generated if the input data change and documents the code to reproduce the analysis in the same file that also produces the report.

Sweave combines the documentation and code chunks together (or their output) into a single document. Stangle extracts only the code from the Sweave file creating an S source file that can be run using `source`. (Code inside `\$expr{}` statements is ignored by Stangle.)

Stangle is just a wrapper to Sweave specifying a different default driver. Alternative drivers can be used: the CRAN package `cacheSweave` and the Bioconductor package `weaver` both provide drivers based on the default driver `RweaveLatex` which incorporate ideas of caching the results of computations on code chunks.

Environment variable `SWEAVE_OPTIONS` can be used to override the initial options set by the driver: it should be a comma-separated set of key=value items, as would be used in a ‘`\$sweaveopts`’ statement in a document.

Non-ASCII source files must contain a line of the form

```
\usepackage[foo]{inputenc}
```

(where ‘foo’ is typically ‘latin1’, ‘latin2’, ‘utf8’ or ‘cp1252’ or ‘cp1250’) or they will give an error. Re-encoding can be turned off completely with argument `encoding` = "bytes".

Syntax Definition

Sweave allows a flexible syntax framework for marking documentation and text chunks. The default is a noweb-style syntax, as alternative a latex-style syntax can be used. (See the user manual for further details.)

If `syntax` = NULL (the default) then the available syntax objects are consulted in turn, and selected if their extension component matches (as a regexp) the file name. Objects `SweaveSyntaxNoweb` (with extension = "[.][rsRS]nw$") and `SweaveSyntaxLaTeX` (with extension = "[.][rsRS]tex$") are supplied, but users or packages can supply others with names matching the pattern `SweaveSyntax.*`.

**SweaveSyntConv**

Convert Sweave Syntax

**Description**

This function converts the syntax of files in *Sweave* format to another Sweave syntax definition.

**Usage**

SweaveSyntConv(file, syntax, output = NULL)
Arguments

- **file**: Name of Sweave source file.
- **syntax**: An object of class `sweavesyntax` or a character string with its name giving the target syntax to which the file is converted.
- **output**: Name of output file, default is to remove the extension from the input file and to add the default extension of the target syntax. Any directory names in file are also removed such that the output is created in the current working directory.

- `rweavelatex`, `rtangle`

Examples

```r
testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")

## convert the file to latex syntax
SweaveSyntConv(testfile, SweaveSyntaxLatex)

## and run it through Sweave
Sweave("Sweave-test-1.Stex")
```

---

**tar**

Create a Tar Archive

Description

Create a tar archive.

Usage

```r
tar(tarfile, files = NULL, compression = c("none", "gzip", "bzip2", "xz"), compression_level = 6, tar = Sys.getenv("tar"), extra_flags = "")
```

Arguments

- **tarfile**: The pathname of the tar file: tilde expansion (see `path.expand`) will be performed. Alternatively, a connection that can be used for binary writes.
- **files**: A character vector of filepaths to be archived: the default is to archive all files under the current directory.
- **compression**: character string giving the type of compression to be used (default none). Can be abbreviated.
tar

- **compression_level**
  - integer: the level of compression. Only used for the internal method.

- **tar**
  - character string: the path to the command to be used. If the command itself contains spaces it needs to be quoted (e.g., by `shQuote`) – but argument `tar` can also contain flags separated from the command by spaces.

- **extra_flags**
  - any extra flags for an external `tar`.

**Details**

This is either a wrapper for a `tar` command or uses an internal implementation in R. The latter is used if `tarfile` is a connection or if the argument `tar` is "internal" or "" (the 'factory-fresh' default). Note that whereas Unix-alike versions of R set the environment variable `TAR`, its value is not the default for this function.

Argument `extra_flags` is passed to an external `tar` and so is platform-dependent. Possibly useful values include ‘-h’ (follow symbolic links, also ‘-L’ on some platforms), ‘--acIs’, ‘--exclude-backups’, ‘--exclude-vcS’ (and similar) and on Windows ‘--force-local’ (so drives can be included in filepaths: however, this is the default for the Rtools `tar`). For GNU `tar`, ‘--format=ustar’ forces a more portable format (the current default in version 1.26 is ‘--format=gnu’, but the manual says the intention is to change to ‘--format=pax’ which GNU incorrectly calls ‘POSIX’ – it was never part of the POSIX standard for `tar`). For libarchive `tar`, ‘--format=ustar’ is more portable than the default.

**Value**

The return code from `system` or 0 for the internal version, invisibly.

**Portability**

The ‘tar’ format no longer has an agreed standard! ‘Unix Standard Tar’ was part of POSIX 1003.1:1998 but has been removed in favour of `pax`, and in any case many common implementations diverged from the former standard. Most R platforms use a version of GNU `tar` (including Rtools on Windows, but the behaviour seems to be changed with each version), Mac OS >= 10.6 and FreeBSD use `bsdttar` from the ‘libarchive’ project, and commercial Unixes will have their own versions.

Known problems arise from

- The handling of file paths of more than 100 bytes. These were unsupported in early versions of `tar`, and supported in one way by POSIX `tar` and in another by GNU `tar` and yet another by the POSIX `pax` command which recent `tar` programs often support. The internal implementation warns on paths of more than 100 bytes, uses the ‘ustar’ way from the 1998 POSIX standard which supports up to 256 bytes (depending on the path: in particular the final component is limited to 100 bytes) if possible, or the GNU way (which is widely supported). Most formats do not record the encoding of file paths.

- (File) links. `tar` was developed on an OS that used hard links, and physical files that were referred to more than once in the list of files to be included were included only once, the remaining instances being added as links. Later a means to include symbolic links was added. The internal implementation supports symbolic links (on OSes that support them), only. Of course, the question arises as to how links should be unpacked on OSes that do not support them: for regular files, at least, file copies can be used.

Names of links in the ‘ustar’ format are restricted to 100 bytes. There is a GNU extension for arbitrarily long link names, but `bsdttar` does not read. The internal method uses the GNU extension, with a warning.
• Header fields, in particular the padding to be used when fields are not full or not used. POSIX
did define the correct behaviour but commonly used implementations did (and still do) not
comply.
• File sizes. The ‘ustar’ format is restricted to 8GB per (uncompressed) file.

For portability, avoid file paths of more than 100 bytes and all links (especially hard links and
symbolic links to directories).
The internal implementation writes only the blocks of 512 bytes required (including trailing blocks
of nulls), unlike GNU tar which by default pads with ‘null’ to a multiple of 20 blocks (10KB).
Implementations which pad differ on whether the block padding should occur before or after com-
pression (or both): padding was designed for improved performance on physical tape drives.

utility pax handles tar formats.
untar.

toLatex  Converting R Objects to BibTeX or LaTeX

Description
These methods convert R objects to character vectors with BibTeX or LaTeX markup.

Usage
toBibtex(object, ...)
toLatex(object, ...)
## S3 method for class 'Bibtex'
print(x, prefix = "", ...)  
## S3 method for class 'Latex'
print(x, prefix = "", ...)

Arguments

object  object of a class for which a toBibtex or toLatex method exists.
x  object of class "Bibtex" or "Latex".
prefix  a character string which is printed at the beginning of each line, mostly used to
insert whitespace for indentation.
...  in the print methods, passed to writelines.

Details
Objects of class "Bibtex" or "Latex" are simply character vectors where each element holds one
line of the corresponding BibTeX or LaTeX file.

citEntry and sessionInfo for examples
txtProgressBar

Description

Text progress bar in the R console.

Usage

txtProgressBar(min = 0, max = 1, initial = 0, char = "=",
    width = NA, title, label, style = 1, file = "")

getTxtProgressBar(pb)
setTxtProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'txtProgressBar''
close(con, ...)

Arguments

- min, max (finite) numeric values for the extremes of the progress bar. Must have min < max.
- initial, value initial or new value for the progress bar. See ‘Details’ for what happens with invalid values.
- char the character (or character string) to form the progress bar.
- width the width of the progress bar, as a multiple of the width of char. If NA, the default, the number of characters is that which fits into getOption("width").
- style the ‘style’ of the bar – see ‘Details’.
- file an open connection object or "" which indicates the console: stderr() might be useful here.
- pb, con an object of class "txtProgressBar".
- title, label ignored, for compatibility with other progress bars.
- ... for consistency with the generic.

Details

txtProgressBar will display a progress bar on the R console (or a connection) via a text representation.

setTxtProgressBar will update the value. Missing (NA) and out-of-range values of value will be (silently) ignored. (Such values of initial cause the progress bar not to be displayed until a valid value is set.)

The progress bar should be closed when finished with: this outputs the final newline character.

style = 1 and style = 2 just shows a line of char. They differ in that style = 2 redraws the line each time, which is useful if other code might be writing to the R console. style = 3 marks the end of the range by | and gives a percentage to the right of the bar.
Value

For txtProgressBar an object of class "txtProgressBar".

For getTxtProgressBar and setTxtProgressBar, a length-one numeric vector giving the previous value (invisibly for setTxtProgressBar).

Note

Using style 2 or 3 or reducing the value with style = 1 uses ‘\r’ to return to the left margin – the interpretation of carriage return is up to the terminal or console in which R is running, and this is liable to produce ugly output on a connection other than a terminal, including when stdout() is redirected to a file.

See Also

tkProgressBar.

Windows versions of R also have winProgressBar.

Examples

```r
# slow
testit <- function(x = sort(runif(20)), ...) {
  pb <- txtProgressBar(...) 
  for(i in c(0, x, 1)) {Sys.sleep(0.5); setTxtProgressBar(pb, i)}
  Sys.sleep(1)
  close(pb)
}
testit()
testit(runif(10))
testit(style = 3)
```

---

**type.convert**  
*Type Conversion on Character Variables*

Description

Convert a character vector to logical, integer, numeric, complex or factor as appropriate.

Usage

```r
type.convert(x, na.strings = "NA", as.is = FALSE, dec = ".",
numerals = c("allow.loss", "warn.loss", "no.loss"))
```

Arguments

- **x**  
a character vector.

- **na.strings**  
a vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric or complex vectors.

- **as.is**  
logical. See ‘Details’.

- **dec**  
the character to be assumed for decimal points.
**Details**

This is principally a helper function for `read.table`. Given a character vector, it attempts to convert it to logical, integer, numeric or complex, and failing that converts it to factor unless `as.is = TRUE`. The first type that can accept all the non-missing values is chosen.

Vectors which are entirely missing values are converted to logical, since `NA` is primarily logical.

Vectors containing just `F`, `T`, `FALSE`, `TRUE` and values from `na.strings` are converted to logical. Vectors containing optional whitespace followed by decimal constants representable as R integers or values from `na.strings` are converted to integer. Other vectors containing optional whitespace followed by other decimal or hexadecimal constants (see `NumericConstants`), or `NaN`, `Inf` or `infinity` (ignoring case) or values from `na.strings` are converted to numeric. As from R 3.1.0, where converting inputs to numeric or complex would result in loss of accuracy they are returned as strings (for `as.is = TRUE`) or factors.

Since this is a helper function, the caller should always pass an appropriate value of `as.is`.

**Value**

An atomic vector or (for `as.is = FALSE`) a factor.

**See Also**

`read.table`

---

**untar**

*Extract or List Tar Archives*

**Description**

Extract files from or list a tar archive.

**Usage**

```r
untar(tarfile, files = NULL, list = FALSE, exdir = ".",
compressed = NA, extras = NULL, verbose = FALSE,
restore_times = TRUE, tar = Sys.getenv("TAR"))
```
Arguments

- **tarfile**: The pathname of the tar file: tilde expansion (see `path.expand`) will be performed. Alternatively, a connection that can be used for binary reads.
- **files**: A character vector of recorded filepaths to be extracted: the default is to extract all files.
- **list**: If TRUE, list the files (the equivalent of `tar -tf`). Otherwise extract the files (the equivalent of `tar -xf`).
- **exdir**: The directory to extract files to (the equivalent of `tar Mc`). It will be created if necessary.
- **compressed**: logical or character. Values "gzip", "bzip2" and "xz" select that form of compression (and may be abbreviated to the first letter). TRUE indicates gzip compression, FALSE no known compression (but an external `tar` command may detect compression autamagically), and NA (the default) that the type is inferred from the file header.
- **extras**: NULL or a character string: further command-line flags such as ‘-p’ to be passed to an external `tar` program.
- **verbose**: logical: if true echo the command used.
- **restore_times**: logical. If true (default) restore file modification times. If false, the equivalent of the ‘-m’ flag. Times in tarballs are supposed to be in UTC, but tarballs are submitted to CRAN with times in the future or far past: this argument allows such times to be discarded.
- **tar**: character string: the path to the command to be used. If the command itself contains spaces it needs to be quoted – but `tar` can also contain flags separated from the command by spaces.

Details

This is either a wrapper for a `tar` command or for an internal implementation written in R. The latter is used if `tarfile` is a connection or if the argument `tar` is "internal" or "" (except on Windows, when `tar.exe` is tried first).

What options are supported will depend on the `tar` used. Modern GNU flavours of `tar` will support compressed archives, and since 1.15 are able to detect the type of compression automatically: version 1.20 added support for lzma and version 1.22 for xz compression using LZMA2. OS X 10.6 and later (and FreeBSD and some other OSes) have a `tar` (also known as bsdtar) from the ‘libarchive’ project which can also detect gzip and bzip2 compression automatically. For other flavours of `tar`, environment variable `R_GZIPCMD` gives the command to decompress gzip and compress files, and `R_BZIPCMD` for bzip2 files.

Arguments `compressed`, `extras` and `verbose` are only used when an external `tar` is used.

The internal implementation restores symbolic links as links on a Unix-alike, and as file copies on Windows (which works only for existing files, not for directories), and hard links as links. If the linking operation fails (as it may on a FAT file system), a file copy is tried. Since it uses `gzfile` to read a file it can handle files compressed by any of the methods that function can handle: at least compress, gzip, bzip2 and xz compression, and some types of lzma compression. It does not guard against restoring absolute file paths, as some `tar` implementations do. It will create the parent directories for directories or files in the archive if necessary. It handles the standard (USTAR/POSIX), GNU and pax ways of handling file paths of more than 100 bytes, and the GNU way of handling link targets of more than 100 bytes.

You may see warnings from the internal implementation such as
unsupported entry type 'x'

This often indicates an invalid archive: entry types "A-Z" are allowed as extensions, but other types are reserved. The only thing you can do with such an archive is to find a tar program that handles it, and look carefully at the resulting files. There may also be the warning

using pax extended headers

This is indicates that additional information may have been discarded, such as ACLs, encodings ..., and long path and link names are only used as from R 2.15.3.

The standards only support ASCII filenames (indeed, only alphanumeric plus period, underscore and hyphen). untar makes no attempt to map filenames to those acceptable on the current system, and treats the filenames in the archive as applicable without any re-encoding in the current locale.

Value

If list = TRUE, a character vector of (relative or absolute) paths of files contained in the tar archive. Otherwise the return code from system, invisibly.

See Also

tar, unzip.

---

unzip

Extract or List Zip Archives

Description

Extract files from or list a zip archive.

Usage

```r
unzip(zipfile, files = NULL, list = FALSE, overwrite = TRUE,
     junkpaths = FALSE, exdir = ".", unzip = "internal",
     setTimes = FALSE)
```

Arguments

- **zipfile**
  
  The pathname of the zip file: tilde expansion (see `path.expand`) will be performed.

- **files**
  
  A character vector of recorded filepaths to be extracted: the default is to extract all files.

- **list**
  
  If TRUE, list the files and extract none. The equivalent of `unzip -l`.

- **overwrite**
  
  If TRUE, overwrite existing files, otherwise ignore such files. The equivalent of `unzip -o`.

- **junkpaths**
  
  If TRUE, use only the basename of the stored filepath when extracting. The equivalent of `unzip -j`.

- **exdir**
  
  The directory to extract files to (the equivalent of `unzip -d`). It will be created if necessary.
update.packages

unzip

The method to be used. An alternative is to use `getOption("unzip"), which on a Unix-alike may be set to the path to a unzip program.

setTimes

logical. For the internal method only, should the file time be set based on the times in the zip file? (NB: this applies to files, not to directories.

Value

If `list = TRUE`, a data frame with columns `Name` (character) `Length` (the size of the uncompressed file, numeric) and `Date` (of class "POSIXct").

Otherwise for the "internal" method, a character vector of the filenames extracted to, invisibly.

Note

The default internal method is a minimal implementation, principally designed for Windows' users to be able to unpack Windows binary packages without external software. It does not (for example) support Unicode filenames as introduced in zip 3.0: for that use `unzip = "unzip" with unzip 6.00 or later. (It does have support for files of more than 4GB and bzip2 compression.)

If `unzip` specifies a program, the format of the dates listed with `list = TRUE is unknown (on Windows it can even depend on the current locale) and the return values could be `NA` or expressed in the wrong time zone or misinterpreted (the latter being far less likely as from `unzip 6.00`).

File times in zip files are stored in the style of MS-DOS, as local times to an accuracy of 2 seconds. This is not very useful when transferring zip files between machines (even across continents), so we chose not to restore them by default.

Source

The internal C code uses zlib and is in particular based on the contributed 'minizip' application in the zlib sources (from `http://zlib.net`) by Gilles Vollant.

`unz` to read a single component from a zip file.

`zip`.

update.packages

\textit{Compare Installed Packages with CRAN-like Repositories}

\textbf{Description}

old.packages indicates packages which have a (suitable) later version on the repositories whereas update.packages offers to download and install such packages.

new.packages looks for (suitable) packages on the repositories that are not already installed, and optionally offers them for installation.
Usage

update.packages(lib.loc = NULL, repos = getOption("repos"),
    contriburl = contrib.url(repos, type),
    method, instlib = NULL,
    ask = TRUE, available = NULL,
    oldPkgs = NULL, ..., checkBuilt = FALSE,
    type = getOption("pkgType"))

old.packages(lib.loc = NULL, repos = getOption("repos"),
    contriburl = contrib.url(repos, type),
    instPkgs = installed.packages(lib.loc = lib.loc),
    method, available = NULL, checkBuilt = FALSE,
    type = getOption("pkgType"))

new.packages(lib.loc = NULL, repos = getOption("repos"),
    contriburl = contrib.url(repos, type),
    instPkgs = installed.packages(lib.loc = lib.loc),
    method, available = NULL, ask = FALSE, ..., 
    type = getOption("pkgType"))

Arguments

lib.loc character vector describing the location of R library trees to search through (and update packages therein), or NULL for all known trees (see .libPaths).
repos character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as "http://cran.us.r-project.org".
contriburl URL(s) of the contrib sections of the repositories. Use this argument if your repository is incomplete. Overrides argument repos. Incompatible with type = "both".
method Download method, see download.file. Unused if a non-NULL available is supplied.
instlib character string giving the library directory where to install the packages.
ask logical indicating whether to ask the user to select packages before they are downloaded and installed, or the character string "graphics", which brings up a widget to allow the user to (de-)select from the list of packages which could be updated. (The latter value only works on systems with a GUI version of select.list, and is otherwise equivalent to ask = TRUE.)
available an object as returned by available.packages listing packages available at the repositories, or NULL which makes an internal call to available.packages. Incompatible with type = "both".
checkBuilt If TRUE, a package built under an earlier major.minor version of R (e.g., 3.1) is considered to be 'old'.
oldPkgs if specified as non-NULL, update.packages() only considers these packages for updating. This may be a character vector of package names or a matrix as returned by old.packages.
instPkgs by default all installed packages, installed.packages(lib.loc = lib.loc). A subset can be specified; currently this must be in the same (character matrix) format as returned by installed.packages().
...
Arguments such as destdir and dependencies to be passed to install.packages.

**type** character, indicating the type of package to download and install. See *install.packages*.

**Details**

`old.packages` compares the information from `available.packages` with that from `instPkgs` (computed by `installed.packages` by default) and reports installed packages that have newer versions on the repositories or, if `checkBuilt = TRUE`, that were built under an earlier minor version of R (for example built under 3.0.x when running R 3.1.0). (For binary package types here is no check that the version on the repository was built under the current minor version of R, but it is advertised as being suitable for this version.)

`new.packages` does the same comparison but reports uninstalled packages that are available at the repositories. If `ask != FALSE` it asks which packages should be installed in the first element of `lib.loc`.

The main function of the set is `update.packages`. First a list of all packages found in `lib.loc` is created and compared with those available at the repositories. If `ask = TRUE` (the default) packages with a newer version are reported and for each one the user can specify if it should be updated. If so the packages are downloaded from the repositories and installed in the respective library path (or `inst` if specified).

For how the list of suitable available packages is determined see `available.packages`. `available = NULL` make a call to `available.packages(contriburl = contriburl, method = method)` and hence by default filters on R version, OS type and removes duplicates.

**Value**

`update.packages` returns NULL invisibly.

For `old.packages`, NULL or a matrix with one row per package, row names the package names and column names "Package", "LibPath", "Installed" (the version), "Built" (the version built under), "ReposVer" and "Repository".

For `new.packages` a character vector of package names, *after* any selected via `ask` have been installed.

**Warning**

Take care when using dependencies (passed to `install.packages`) with `update.packages`, for it is unclear where new dependencies should be installed. The current implementation will only allow it if all the packages to be updated are in a single library, when that library will be used.

**See Also**

`install.packages`, `available.packages`, `download.packages`, `installed.packages`, `contrib.url`.

The options listed for `install.packages` under `options`.

See `download.file` for how to handle proxies and other options to monitor file transfers.

`INSTALL`, `REMOVE`, `remove.packages`, `library`, `.packages`, `read.dcf`

The ‘R Installation and Administration’ manual for how to set up a repository.
url.show  

*Display a text URL*

**Description**

Extension of `file.show` to display text files from a remote server.

**Usage**

```r
default(url, title = url, file = tempfile(),
          delete.file = TRUE, method, ...)
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>url</code></td>
<td>The URL to read from.</td>
</tr>
<tr>
<td><code>title</code></td>
<td>Title for the browser.</td>
</tr>
<tr>
<td><code>file</code></td>
<td>File to copy to.</td>
</tr>
<tr>
<td><code>delete.file</code></td>
<td>Delete the file afterwards?</td>
</tr>
<tr>
<td><code>method</code></td>
<td>File transfer method: see <code>download.file</code></td>
</tr>
<tr>
<td><code>...</code></td>
<td>Arguments to pass to <code>file.show</code>.</td>
</tr>
</tbody>
</table>

**Note**

Since this is for text files, it will convert to CRLF line endings on Windows.

**See Also**

`url.file.show, download.file`

**Examples**

```r
## Not run: url.show("http://lib.stat.cmu.edu/datasets/csb/ch3a.txt")
```

---

**URLencode**  

*Encode or Decode a (partial) URL*

**Description**

Functions to encode or decode characters in URLs.

**Usage**

```r
URLencode(URL, reserved = FALSE)

URLdecode(URL)
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>URL</code></td>
<td>A character string.</td>
</tr>
<tr>
<td><code>reserved</code></td>
<td>should reserved characters be encoded? See 'Details'.</td>
</tr>
</tbody>
</table>
Details

Characters in a URL other than the English alphanumeric characters and `~ _ .` should be encoded as % plus a two-digit hexadecimal representation, and any single-byte character can be so encoded. (Multi-byte characters are encoded as byte-by-byte.)

In addition, `! $ & ' ( ) * + , ; = : / ? @ [ ]` are reserved characters, and should be encoded unless used in their reserved sense, which is scheme specific. The default in `URLencode` is to leave them alone, which is appropriate for `file://` URLs, but probably not for `http://` ones.

Value

A character string.

References

Examples

```r
(y <- URLencode("a url with spaces and / and @"))
URLdecode(y)
(y <- URLencode("a url with spaces and / and @", reserved = TRUE))
URLdecode(y)
URLdecode("ab%20cd")
```

Description

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

See Also

`Deprecated`, `Defunct`

View

Invoke a Data Viewer

Description

Invoke a spreadsheet-style data viewer on a matrix-like R object.

Usage

`View(x, title)`
Arguments

x an \texttt{R} object which can be coerced to a data frame with non-zero numbers of rows and columns.

title title for viewer window. Defaults to name of \texttt{x} prefixed by \texttt{Data:}.

Details

Object \texttt{x} is coerced (if possible) to a data frame, and all non-numeric columns are then coerced to character. The object is then viewed in a spreadsheet-like data viewer, a read-only version of \texttt{data.entry}.

If there are row names on the data frame that are not \texttt{1:nrow}, they are displayed in a separate first column called \texttt{rownames}.

Objects with zero columns or zero rows are not accepted.

The array of cells can be navigated by the cursor keys and Home, End, Page Up and Page Down (where supported by X11) as well as Enter and Tab.

Value

Invisible \texttt{NULL}. The functions puts up a window and returns immediately: the window can be closed via its controls or menus.

See Also

\texttt{edit.data.frame, data.entry}.

---

\texttt{vignette} View or List Package Vignettes

Description

View a specified package vignette, or list the available ones.

Usage

\texttt{vignette(topic, package = NULL, lib.loc = NULL, all = TRUE)}

## S3 method for class 'vignette'
\texttt{print(x, ...)}

## S3 method for class 'vignette'
\texttt{edit(name, ...)}

Arguments

\texttt{topic} a character string giving the (base) name of the vignette to view. If omitted, all vignettes from all installed packages are listed.

\texttt{package} a character vector with the names of packages to search through, or \texttt{NULL} in which ‘all’ packages (as defined by argument \texttt{all}) are searched.

\texttt{lib.loc} a character vector of directory names of \texttt{R} libraries, or \texttt{NULL}. The default value of \texttt{NULL} corresponds to all libraries currently known.
vignette

all logical; if TRUE search all available packages in the library trees specified by
lib.loc, and if FALSE, search only attached packages.
x, name Object of class vignette.
... Ignored by the print method, passed on to file.edit by the edit method.

Details

Function vignette returns an object of the same class, the print method opens a viewer for it. The program specified by the pdfviewer option is used for viewing PDF versions of vignettes. If several vignettes have PDF/HTML versions with base name identical to topic, the first one found is used.

If no topics are given, all available vignettes are listed. The corresponding information is returned in an object of class "packageIQR".

The edit method copies the R code extracted from the vignette to a temporary file and opens the file in an editor (see edit). This makes it very easy to execute the commands line by line, modify them in any way you want to help you test variants, etc.

See Also

browseVignettes for an HTML-based vignette browser.

Examples

```r
## List vignettes from all *attached* packages
vignette(all = FALSE)

## List vignettes from all *installed* packages (can take a long time!):
vignette(all = TRUE)

## Not run:
## Open the grid intro vignette
vignette("grid")

## The same
v1 <- vignette("grid")
print(v1)

## Now let us have a closer look at the code
edit(v1)

## An alternative way of extracting the code,
## R file is written to current working directory
Stangle(v1)$file

## A package can have more than one vignette (package grid has several):
vignette(package = "grid")
vignette("rotated")

## The same, but without searching for it:
vignette("rotated", package = "grid")

## End(Not run)
```
write.table

Data Output

Description

write.table prints its required argument x (after converting it to a data frame if it is not one nor a matrix) to a file or connection.

Usage

write.table(x, file = "", append = FALSE, quote = TRUE, sep = " ",
eol = "\n", na = "NA", dec = ".", row.names = TRUE,
col.names = TRUE, qmethod = c("escape", "double"),
fileEncoding = "")

write.csv(...)
write.csv2(...)

Arguments

x  the object to be written, preferably a matrix or data frame. If not, it is attempted to coerce x to a data frame.

file either a character string naming a file or a connection open for writing. "" indicates output to the console.

append  logical. Only relevant if file is a character string. If TRUE, the output is appended to the file. If FALSE, any existing file of the name is destroyed.

quote  a logical value (TRUE or FALSE) or a numeric vector. If TRUE, any character or factor columns will be surrounded by double quotes. If a numeric vector, its elements are taken as the indices of columns to quote. In both cases, row and column names are quoted if they are written. If FALSE, nothing is quoted.

sep  the field separator string. Values within each row of x are separated by this string.

eol  the character(s) to print at the end of each line (row). For example, eol = "\r\n" will produce Windows' line endings on a Unix-alike OS, and eol = "\r" will produce files as expected by Excel:mac 2004.

na  the string to use for missing values in the data.

dec  the string to use for decimal points in numeric or complex columns: must be a single character.

row.names  either a logical value indicating whether the row names of x are to be written along with x, or a character vector of row names to be written.

col.names  either a logical value indicating whether the column names of x are to be written along with x, or a character vector of column names to be written. See the section on 'CSV files' for the meaning of col.names = NA.

qmethod  a character string specifying how to deal with embedded double quote characters when quoting strings. Must be one of "escape" (default for write.table), in which case the quote character is escaped in C style by a backslash, or "double" (default for write.csv and write.csv2), in which case it is doubled. You can specify just the initial letter.
fileEncoding character string: if non-empty declares the encoding to be used on a file (not a connection) so the character data can be re-encoded as they are written. See file.

... arguments to write.table: append, col.names, sep, dec and qmethod cannot be altered.

Details

If the table has no columns the rownames will be written only if row.names = TRUE, and vice versa.

Real and complex numbers are written to the maximal possible precision.

If a data frame has matrix-like columns these will be converted to multiple columns in the result (via as.matrix) and so a character col.names or a numeric quote should refer to the columns in the result, not the input. Such matrix-like columns are unquoted by default.

Any columns in a data frame which are lists or have a class (e.g., dates) will be converted by the appropriate as.character method: such columns are unquoted by default. On the other hand, any class information for a matrix is discarded and non-atomic (e.g., list) matrices are coerced to character.

Only columns which have been converted to character will be quoted if specified by quote.

The dec argument only applies to columns that are not subject to conversion to character because they have a class or are part of a matrix-like column (or matrix), in particular to columns protected by I(). Use options("OutDec") to control such conversions.

In almost all cases the conversion of numeric quantities is governed by the option "scipen" (see options), but with the internal equivalent of digits = 15. For finer control, use format to make a character matrix/data frame, and call write.table on that.

These functions check for a user interrupt every 1000 lines of output.

If file is a non-open connection, an attempt is made to open it and then close it after use.

To write a Unix-style file on Windows, use a binary connection e.g. file = file("filename", "wb").

CSV files

By default there is no column name for a column of row names. If col.names = NA and row.names = TRUE a blank column name is added, which is the convention used for CSV files to be read by spreadsheets. Note that such CSV files can be read in R by

\[ \text{read.csv(file = "<filename>", row.names = 1)} \]

write.csv and write.csv2 provide convenience wrappers for writing CSV files. They set sep and dec (see below), qmethod = "double", and col.names to NA if row.names = TRUE (the default) and to TRUE otherwise.

write.csv uses "," for the decimal point and a comma for the separator.

write.csv2 uses a comma for the decimal point and a semicolon for the separator, the Excel convention for CSV files in some Western European locales.

These wrappers are deliberately inflexible: they are designed to ensure that the correct conventions are used to write a valid file. Attempts to change append, col.names, sep, dec or qmethod are ignored, with a warning.

CSV files do not record an encoding, and this causes problems if they are not ASCII for many other applications. Windows Excel 2007/10 will open files (e.g., by the file association mechanism)
correctly if they are ASCII or UTF-16 (use fileEncoding = "UTF-16LE") or perhaps in the current Windows codepage (e.g., "CP1252"), but the ‘Text Import Wizard’ (from the ‘Data’ tab) allows far more choice of encodings. Excel:mac 2004/8 can import only ‘Macintosh’ (which seems to mean Mac Roman), ‘Windows’ (perhaps Latin-1) and ‘PC-8’ files. OpenOffice 3.x asks for the character set when opening the file.

There is an IETF RFC4180 (http://tools.ietf.org/html/rfc4180) for CSV files, which mandates comma as the separator and CRLF line endings. write.csv writes compliant files on Windows: use eol = "\r\n" on other platforms.

Note
write.table can be slow for data frames with large numbers (hundreds or more) of columns: this is inevitable as each column could be of a different class and so must be handled separately. If they are all of the same class, consider using a matrix instead.

See Also
The ‘R Data Import/Export’ manual.
read.table, write.
write.matrix in package MASS.

Examples
## Not run:
## To write a CSV file for input to Excel one might use
x <- data.frame(a = I("a \" quote"), b = pi)
write.table(x, file = "foo.csv", sep = ",", col.names = NA,
qmethod = "double")
## and to read this file back into R one needs
read.table("foo.csv", header = TRUE, sep = ",", row.names = 1)
## NB: you do need to specify a separator if qmethod = "double".

### Alternatively
write.csv(x, file = "foo.csv")
read.csv("foo.csv", row.names = 1)
## or without row names
write.csv(x, file = "foo.csv", row.names = FALSE)
read.csv("foo.csv")

## To write a file in Mac Roman for simple use in Mac Excel 2004/8
write.csv(x, file = "foo.csv", fileEncoding = "macroman")
## or for Windows Excel 2007/10
write.csv(x, file = "foo.csv", fileEncoding = "UTF-16LE")
## End(Not run)

---

zip 

Create Zip archives

Description
A wrapper for an external zip command to create zip archives.
Usage

zip(zipfile, files, flags = "-r9X", extras = "", zip = Sys.getenv("R_ZIPCMD", "zip"))

Arguments

zipfile The pathname of the zip file: tilde expansion (see path.expand) will be performed.
files A character vector of recorded filepaths to be included.
flags A character string of flags to be passed to the command: see ‘Details’.
extras An optional character vector: see ‘Details’.
zip A character string specifying the external command to be used.

Details

On a Unix-alike, the default for zip will by default use the value of R_ZIPCMD, which is set in ‘etc/Renviron’ if an unzip command was found during configuration. On Windows, the default relies on a zip program (for example that from Rtools) being in the path.

The default for flags is that appropriate for zipping up a directory tree in a portable way: see the system-specific help for the zip command for other possibilities.

Argument extras can be used to specify -x or -i followed by a list of filepaths to exclude or include.

Value

The status value returned by the external command, invisibly.

Chapter 15

The KernSmooth package

**bkde**

*Compute a Binned Kernel Density Estimate*

**Description**

Returns x and y coordinates of the binned kernel density estimate of the probability density of the data.

**Usage**

```
bkde(x, kernel = "normal", canonical = FALSE, bandwidth,
     gridsize = 401L, range.x, truncate = TRUE)
```

**Arguments**

- **x** numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.
- **bandwidth** the kernel bandwidth smoothing parameter. Larger values of bandwidth make smoother estimates, smaller values of bandwidth make less smooth estimates. The default is a bandwidth computed from the variance of x, specifically the ‘oversmoothed bandwidth selector’ of Wand and Jones (1995, page 61).
- **kernel** character string which determines the smoothing kernel. kernel can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation.
- **canonical** logical flag: if TRUE, canonically scaled kernels are used.
- **gridsize** the number of equally spaced points at which to estimate the density.
- **range.x** vector containing the minimum and maximum values of x at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.
- **truncate** logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.
Details

This is the binned approximation to the ordinary kernel density estimate. Linear binning is used to obtain the bin counts. For each \( x \) value in the sample, the kernel is centered on that \( x \) and the heights of the kernel at each datapoint are summed. This sum, after a normalization, is the corresponding \( y \) value in the output.

Value

a list containing the following components:

- \( x \) vector of sorted \( x \) values at which the estimate was computed.
- \( y \) vector of density estimates at the corresponding \( x \).

Background

Density estimation is a smoothing operation. Inevitably there is a trade-off between bias in the estimate and the estimate’s variability: large bandwidths will produce smooth estimates that may hide local features of the density; small bandwidths may introduce spurious bumps into the estimate.

References

See Also

density, dpik, hist, ksmooth.

Examples

data(geyser, package="MASS")
x <- geyser$duration
est <- bkde(x, bandwidth=0.25)
plot(est, type="l")

---

**bkde2D**  
*Compute a 2D Binned Kernel Density Estimate*

Description

Returns the set of grid points in each coordinate direction, and the matrix of density estimates over the mesh induced by the grid points. The kernel is the standard bivariate normal density.

Usage

\[
\text{bkde2D}(x, \text{bandwidth}, \text{gridsize} = c(51L, 51L), \text{range.x}, \text{truncate} = \text{TRUE})
\]
Arguments

- **x**: a two-column numeric matrix containing the observations from the distribution whose density is to be estimated. Missing values are not allowed.
- **bandwidth**: numeric vector of length 2, containing the bandwidth to be used in each coordinate direction.
- **gridsize**: vector containing the number of equally spaced points in each direction over which the density is to be estimated.
- **range.x**: a list containing two vectors, where each vector contains the minimum and maximum values of x at which to compute the estimate for each direction. The default minimum in each direction is minimum data value minus 1.5 times the bandwidth for that direction. The default maximum is the maximum data value plus 1.5 times the bandwidth for that direction.
- **truncate**: logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Value

A list containing the following components:

- **x1**: vector of values of the grid points in the first coordinate direction at which the estimate was computed.
- **x2**: vector of values of the grid points in the second coordinate direction at which the estimate was computed.
- **fhat**: matrix of density estimates over the mesh induced by x1 and x2.

Details

This is the binned approximation to the 2D kernel density estimate. Linear binning is used to obtain the bin counts and the Fast Fourier Transform is used to perform the discrete convolutions. For each x1,x2 pair the bivariate Gaussian kernel is centered on that location and the heights of the kernel, scaled by the bandwidths, at each datapoint are summed. This sum, after a normalization, is the corresponding fhat value in the output.

References

See Also

- `bkde`, `density`, `hist`.

Examples

data(geyser, package="MASS")
x <- cbind(geyser$duration, geyser$waiting)
est <- bkde2D(x, bandwidth=c(0.7, 7))
contour(est$x1, est$x2, est$fhat)
persp(est$fhat)
**Compute a Binned Kernel Functional Estimate**

**Description**

Returns an estimate of a binned approximation to the kernel estimate of the specified density functional. The kernel is the standard normal density.

**Usage**

\[ \text{bkfe}(x, \text{drv}, \text{bandwidth}, \text{gridsize} = 401, \text{range.x}, \text{binned} = \text{FALSE}, \text{truncate} = \text{TRUE}) \]

**Arguments**

- **x** numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.
- **drv** order of derivative in the density functional. Must be a non-negative even integer.
- **bandwidth** the kernel bandwidth smoothing parameter. Must be supplied.
- **gridsize** the number of equally-spaced points over which binning is performed.
- **range.x** vector containing the minimum and maximum values of \( x \) at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.
- **binned** logical flag: if \( \text{TRUE} \), then \( x \) and \( y \) are taken to be grid counts rather than raw data.
- **truncate** logical flag: if \( \text{TRUE} \), data with \( x \) values outside the range specified by \( \text{range.x} \) are ignored.

**Details**

The density functional of order \( \text{drv} \) is the integral of the product of the density and its \( \text{drv} \)th derivative. The kernel estimates of such quantities are computed using a binned implementation, and the kernel is the standard normal density.

**Value**

the (scalar) estimated functional.

**Background**

Estimates of this type were proposed by Sheather and Jones (1991).

**References**

Examples

data(geyser, package="MASS")
x <- geyser$duration
est <- bkfe(x, drv=4, bandwidth=0.3)

dpih

Select a Histogram Bin Width

Description

Uses direct plug-in methodology to select the bin width of a histogram.

Usage

dpih(x, scalest = "minim", level = 2L, gridsize = 401L,
     range.x = range(x), truncate = TRUE)

Arguments

x numeric vector containing the sample on which the histogram is to be con-
structed.
scalest estimate of scale.
"stdev" - standard deviation is used.
"iqr" - inter-quartile range divided by 1.349 is used.
"minim" - minimum of "stdev" and "iqr" is used.
level number of levels of functional estimation used in the plug-in rule.
gridsize number of grid points used in the binned approximations to functional estimates.
rangex range over which functional estimates are obtained. The default is the minimum
and maximum data values.
truncate if truncate is TRUE then observations outside of the interval specified by
rangex are omitted. Otherwise, they are used to weight the extreme grid points.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymp-
totically optimal bin width and bandwidths are replaced by kernel estimates, is used. The normal
distribution is used to provide an initial estimate.

Value

the selected bin width.

Background

This method for selecting the bin width of a histogram is described in Wand (1995). It is an exten-
sion of the normal scale rule of Scott (1979) and uses plug-in ideas from bandwidth selection for
kernel density estimation (e.g. Sheather and Jones, 1991).

bins <- seq(min(x)-h, max(x)+h, by=h)
hist(x, breaks=bins)

---

dpik

*Select a Bandwidth for Kernel Density Estimation*

Description

Use direct plug-in methodology to select the bandwidth of a kernel density estimate.

Usage

dpik(x, scalest = "minim", level = 2L, kernel = "normal",
canonical = FALSE, gridsize = 401L, range.x = range(x),
truncate = TRUE)

Arguments

- **x**: numeric vector containing the sample on which the kernel density estimate is to be constructed.
- **scalest**: estimate of scale. "stddev" - standard deviation is used. "iqr" - inter-quartile range divided by 1.349 is used. "minim" - minimum of "stddev" and "iqr" is used.
- **level**: number of levels of functional estimation used in the plug-in rule.
- **kernel**: character string which determines the smoothing kernel. kernel can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation.
- **canonical**: logical flag: if TRUE, canonically scaled kernels are used
- **gridsize**: the number of equally-spaced points over which binning is performed to obtain kernel functional approximation.
dpill

range.x vector containing the minimum and maximum values of x at which to compute the estimate. The default is the minimum and maximum data values.

truncate logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

Value

the selected bandwidth.

Background

This method for selecting the bandwidth of a kernel density estimate was proposed by Sheather and Jones (1991) and is described in Section 3.6 of Wand and Jones (1995).

References

See Also

bkde, density, ksmooth

dpill Select a Bandwidth for Local Linear Regression

Description

Use direct plug-in methodology to select the bandwidth of a local linear Gaussian kernel regression estimate, as described by Ruppert, Sheather and Wand (1995).

Usage

dpill(x, y, blockmax = 5, divisor = 20, trim = 0.01, proptrun = 0.05, gridsize = 401L, range.x, truncate = TRUE)
Arguments

- **x**: numeric vector of x data. Missing values are not accepted.
- **y**: numeric vector of y data. This must be same length as x, and missing values are not accepted.
- **blockmax**: the maximum number of blocks of the data for construction of an initial parametric estimate.
- **divisor**: the value that the sample size is divided by to determine a lower limit on the number of blocks of the data for construction of an initial parametric estimate.
- **trim**: the proportion of the sample trimmed from each end in the x direction before application of the plug-in methodology.
- **proptrun**: the proportion of the range of x at each end truncated in the functional estimates.
- **gridsize**: number of equally-spaced grid points over which the function is to be estimated.
- **range.x**: vector containing the minimum and maximum values of x at which to compute the estimate. For density estimation the default is the minimum and maximum data values with 5% of the range added to each end. For regression estimation the default is the minimum and maximum data values.
- **truncate**: logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The kernel is the standard normal density. Least squares quartic fits over blocks of data are used to obtain an initial estimate. Mallow’s \( C_p \) is used to select the number of blocks.

Value

the selected bandwidth.

Warning

If there are severe irregularities (i.e. outliers, sparse regions) in the x values then the local polynomial smooths required for the bandwidth selection algorithm may become degenerate and the function will crash. Outliers in the y direction may lead to deterioration of the quality of the selected bandwidth.

See Also

- `ksmooth`, `locpoly`
Estimate Functions Using Local Polynomials

Description

Estimates a probability density function, regression function or their derivatives using local polynomials. A fast binned implementation over an equally-spaced grid is used.

Usage

locpoly(x, y, drv = 0L, degree, kernel = "normal", bandwidth, gridsize = 401L, bwdisc = 25, range.x, binned = FALSE, truncate = TRUE)

Arguments

x numeric vector of x data. Missing values are not accepted.
bandwidth the kernel bandwidth smoothing parameter. It may be a single number or an array having length gridsize, representing a bandwidth that varies according to the location of estimation.
y vector of y data. This must be same length as x, and missing values are not accepted.
drv order of derivative to be estimated.
degree degree of local polynomial used. Its value must be greater than or equal to the value of drv. The default value is of degree is drv + 1.
kernel "normal" - the Gaussian density function. Currently ignored.
gridsize number of equally-spaced grid points over which the function is to be estimated.
bwdisc number of logarithmically-equally-spaced bandwidths on which bandwidth is discretised, to speed up computation.
range.x vector containing the minimum and maximum values of x at which to compute the estimate.
binned logical flag: if TRUE, then x and y are taken to be grid counts rather than raw data.
truncate logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.
if y is specified, a local polynomial regression estimate of $E[Y|X]$ (or its derivative) is computed. If y is missing, a local polynomial estimate of the density of x (or its derivative) is computed.

a list containing the following components:

- **x** vector of sorted x values at which the estimate was computed.
- **y** vector of smoothed estimates for either the density or the regression at the corresponding x.

**Details**

Local polynomial fitting with a kernel weight is used to estimate either a density, regression function or their derivatives. In the case of density estimation, the data are binned and the local fitting procedure is applied to the bin counts. In either case, binned approximations over an equally-spaced grid is used for fast computation. The bandwidth may be either scalar or a vector of length gridsize.

addterm

Source

References

addterm

Try All One-Term Additions to a Model

Description

Try fitting all models that differ from the current model by adding a single term from those supplied, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

Usage

```
addterm(object, ...)  
```

```
## Default S3 method:
addterm(object, scope, scale = 0, test = c("none", "Chisq"),
        k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'lm'
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
        k = 2, sorted = FALSE, ...)

## S3 method for class 'glm'
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
        k = 2, sorted = FALSE, trace = FALSE, ...)
```

Arguments

- **object**: An object fitted by some model-fitting function.
- **scope**: a formula specifying a maximal model which should include the current one. All additional terms in the maximal model with all marginal terms in the original model are tried.
- **scale**: used in the definition of the AIC statistic for selecting the models, currently only for `lm`, `aov` and `glm` models. Specifying `scale` asserts that the residual standard error or dispersion is known.
- **test**: should the results include a test statistic relative to the original model? The F test is only appropriate for `lm` and `aov` models, and perhaps for some over-dispersed `glm` models. The Chisq test can be an exact test (`lm` models with known scale) or a likelihood-ratio test depending on the method.
- **k**: the multiple of the number of degrees of freedom used for the penalty. Only `k=2` gives the genuine AIC: \( k = \log(n) \) is sometimes referred to as BIC or SBC.
- **sorted**: should the results be sorted on the value of AIC?
- **trace**: if `TRUE` additional information may be given on the fits as they are tried.
- **...**: arguments passed to or from other methods.
Details

The definition of AIC is only up to an additive constant: when appropriate (lm models with specified scale) the constant is taken to be that used in Mallows’ Cp statistic and the results are labelled accordingly.

Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

References

anova.negbin  Likelihood Ratio Tests for Negative Binomial GLMs

Description
Method function to perform sequential likelihood ratio tests for Negative Binomial generalized linear models.

Usage
```r
## S3 method for class 'negbin'
anova(object, ..., test = "Chisq")
```
Arguments

object Fitted model object of class "negbin", inheriting from classes "glm" and "lm", specifying a Negative Binomial fitted GLM. Typically the output of glm.nb().

... Zero or more additional fitted model objects of class "negbin". They should form a nested sequence of models, but need not be specified in any particular order.

test Argument to match the test argument of anova.glm. Ignored (with a warning if changed) if a sequence of two or more Negative Binomial fitted model objects is specified, but possibly used if only one object is specified.

Details

This function is a method for the generic function anova() for class "negbin". It can be invoked by calling anova(x) for an object x of the appropriate class, or directly by calling anova.negbin(x) regardless of the class of the object.

Note

If only one fitted model object is specified, a sequential analysis of deviance table is given for the fitted model. The theta parameter is kept fixed. If more than one fitted model object is specified they must all be of class "negbin" and likelihood ratio tests are done of each model within the next. In this case theta is assumed to have been re-estimated for each model.

glm.nb, negative.binomial, summary.negbin

Examples

```r
m1 <- glm.nb(Days ~ Eth*Age*Lrn*Sex, quine, link = log)
m2 <- update(m1, . ~ . ~ Eth:Age:Lrn:Sex)
anova(m2, m1)
anova(m2)
```

area

Adaptive Numerical Integration

Description

Integrate a function of one variable over a finite range using a recursive adaptive method. This function is mainly for demonstration purposes.

Usage

```r
area(f, a, b, ..., fa = f(a, ...), fb = f(b, ...),
     limit = 10, eps = 1e-05)
```
Arguments

f  The integrand as an S function object. The variable of integration must be the first argument.
a  Lower limit of integration.
b  Upper limit of integration.
...  Additional arguments needed by the integrand.
fa  Function value at the lower limit.
fb  Function value at the upper limit.
limit  Limit on the depth to which recursion is allowed to go.
eps  Error tolerance to control the process.

Details

The method divides the interval in two and compares the values given by Simpson’s rule and the trapezium rule. If these are within eps of each other the Simpson’s rule result is given, otherwise the process is applied separately to each half of the interval and the results added together.

Value

The integral from a to b of f(x).

References

Examples

area(sin, 0, pi) # integrate the sin function from 0 to pi.

bacteria    Presence of Bacteria after Drug Treatments

Description

Tests of the presence of the bacteria *H. influenzae* in children with otitis media in the Northern Territory of Australia.

Usage

bacteria
Format

This data frame has 220 rows and the following columns:

- **y** presence or absence: a factor with levels *n* and *y*.
- **ap** active/placebo: a factor with levels *a* and *p*.
- **hilo** hi/low compliance: a factor with levels *hi* and *lo*.
- **week** numeric: week of test.
- **ID** subject ID: a factor.
- **trt** a factor with levels placebo, drug and drug+, a re-coding of **ap** and **hilo**.

Details

Dr A. Leach tested the effects of a drug on 50 children with a history of otitis media in the Northern Territory of Australia. The children were randomized to the drug or the a placebo, and also to receive active encouragement to comply with taking the drug.

The presence of *H. influenzae* was checked at weeks 0, 2, 4, 6 and 11: 30 of the checks were missing and are not included in this data frame.

```
bandwidth.nrd

Bandwidth for density() via Normal Reference Distribution

Description
A well-supported rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator.

Usage
bandwidth.nrd(x)

Arguments
x
A data vector.

Value
A bandwidth on a scale suitable for the width argument of density.

References

Examples
# The function is currently defined as
function(x)
{
  r <- quantile(x, c(0.25, 0.75))
  h <- (r[2] - r[1])/1.34
  4 * 1.06 * min(sqrt(var(x)), h) * length(x)^(-1/5)
}

bcv

Biased Cross-Validation for Bandwidth Selection

Description
Uses biased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

Usage
bcv(x, nb = 1000, lower, upper)

Arguments
x
a numeric vector

nb
number of bins to use.

lower, upper
Range over which to minimize. The default is almost always satisfactory.
Value

a bandwidth

**beav1**

*Body Temperature Series of Beaver 1*

Description

Reynolds (1994) describes a small part of a study of the long-term temperature dynamics of beaver *Castor canadensis* in north-central Wisconsin. Body temperature was measured by telemetry every 10 minutes for four females, but data from a one period of less than a day for each of two animals is used there.

Usage

beav1

Format

The beav1 data frame has 114 rows and 4 columns. This data frame contains the following columns:

day  Day of observation (in days since the beginning of 1990), December 12–13.
time  Time of observation, in the form 0330 for 3.30am.
temp  Measured body temperature in degrees Celsius.
activ  Indicator of activity outside the retreat.

Note

The observation at 22:20 is missing.

**Biopsy Data on Breast Cancer Patients**

**Description**

This breast cancer database was obtained from the University of Wisconsin Hospitals, Madison from Dr. William H. Wolberg. He assessed biopsies of breast tumours for 699 patients up to 15 July 1992; each of nine attributes has been scored on a scale of 1 to 10, and the outcome is also known. There are 699 rows and 11 columns.

**Usage**

biopsy

**Format**

This data frame contains the following columns:

- id: sample code number (not unique).
- vQ: clump thickness.
- vR: uniformity of cell size.
- vS: uniformity of cell shape.
- vT: marginal adhesion.
- vU: single epithelial cell size.
- vV: bland chromatin.
- vW: normal nucleoli.
- vX: mitoses.
- class: "benign" or "malignant".

**birthwt**

*Risk Factors Associated with Low Infant Birth Weight*

**Description**

The *birthwt* data frame has 189 rows and 10 columns. The data were collected at Baystate Medical Center, Springfield, Mass during 1986.

**Usage**

`birthwt`

**Format**

This data frame contains the following columns:

- `lwt` indicator of birth weight less than 2.5 kg.
- `age` mother’s age in years.
- `ht` history of hypertension.
- `fthe` presence of uterine irritability.
- `bwt` birth weight in grams.
- `race` mother’s race (1 = white, 2 = black, 3 = other).
- `pt1` number of previous premature labours.
- `smoke` smoking status during pregnancy.
- `ui` presence of uterine irritability.
- `ftv` number of physician visits during the first trimester.
Source

References

Examples

```r
bwt <- with(birthwt, {
  race <- factor(race, labels = c("white", "black", "other"))
  ptd <- factor(ptd > 0)
  ftv <- factor(ftv)
  levels(ftv)[-c(1, 2)] <- "2+
  data.frame(low = factor(low), age, lwt, race, smoke = (smoke > 0),
    ptd, ht = (ht > 0), ui = (ui > 0), ftv)
})
options(contrasts = c("contr.treatment", "contr.poly"))
glm(low ~ ., binomial, bwt)
```

---

**Boston**

*Housing Values in Suburbs of Boston*

Description

The Boston data frame has 506 rows and 14 columns.

Usage

Boston

Format

This data frame contains the following columns:

- **crim** per capita crime rate by town.
- **zn** proportion of residential land zoned for lots over 25,000 sq.ft.
- **indus** proportion of non-retail business acres per town.
- **chas** Charles River dummy variable (= 1 if tract bounds river; 0 otherwise).
- **nox** nitrogen oxides concentration (parts per 10 million).
- **rm** average number of rooms per dwelling.
- **age** proportion of owner-occupied units built prior to 1940.
- **dis** weighted mean of distances to five Boston employment centres.
- **rad** index of accessibility to radial highways.
- **tax** full-value property-tax rate per \$10,000.
- **ptratio** pupil-teacher ratio by town.
- **black** 1000(Bk − 0.63)^2 where Bk is the proportion of blacks by town.
- **lstat** lower status of the population (percent).
- **medv** median value of owner-occupied homes in \$1000s.
boxcox

**Box-Cox Transformations for Linear Models**

### Description

Computes and optionally plots profile log-likelihoods for the parameter of the Box-Cox power transformation.

### Usage

```r
boxcox(object, ...)  
```

#### Default S3 method:

```r
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,  
        interp, eps = 1/50, xlab = expression(lambda),  
        ylab = "log-Likelihood", ...)  
```

#### S3 method for class 'formula'

```r
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,  
        interp, eps = 1/50, xlab = expression(lambda),  
        ylab = "log-Likelihood", ...)  
```

#### S3 method for class 'lm'

```r
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,  
        interp, eps = 1/50, xlab = expression(lambda),  
        ylab = "log-Likelihood", ...)  
```

### Arguments

- **object**: a formula or fitted model object. Currently only `lm` and `aov` objects are handled.
- **lambda**: vector of values of lambda – default (-2, 2) in steps of 0.1.
- **plotit**: logical which controls whether the result should be plotted.
- **interp**: logical which controls whether spline interpolation is used. Default to TRUE if plotting with lambda of length less than 100.
- **eps**: Tolerance for lambda = 0; defaults to 0.02.
- **xlab**: defaults to "lambda".
- **ylab**: defaults to "log-Likelihood".
- **...**: additional parameters to be used in the model fitting.

### Value

A list of the lambda vector and the computed profile log-likelihood vector, invisibly if the result is plotted.

**Source**

Side Effects

If `plotit = TRUE` plots log-likelihood vs `lambda` and indicates a 95% confidence interval about the maximum observed value of `lambda`. If `interp = TRUE`, spline interpolation is used to give a smoother plot.

References

Examples

```r
boxcox(Volume ~ log(Height) + log(Girth), data = trees,
       lambda = seq(-0.25, 0.25, length = 10))

boxcox(Days+1 ~ Eth*Sex*Age*Lrn, data = quine,
       lambda = seq(-0.05, 0.45, len = 20))
```

cabbages

Data from a cabbage field trial

Description

The cabbages data set has 60 observations and 4 variables

Usage

cabbages

Format

This data frame contains the following columns:

- **Cult** Factor giving the cultivar of the cabbage, two levels: c39 and c52.
- **Date** Factor specifying one of three planting dates: d16, d20 or d21.
- **HeadWt** Weight of the cabbage head, presumably in kg.
- **VitC** Ascorbic acid content, in undefined units.

Source

References

### caith

**Colours of Eyes and Hair of People in Caithness**

**Description**

Data on the cross-classification of people in Caithness, Scotland, by eye and hair colour. The region of the UK is particularly interesting as there is a mixture of people of Nordic, Celtic and Anglo-Saxon origin.

**Usage**

caith

**Format**

A 4 by 5 table with rows the eye colours (blue, light, medium, dark) and columns the hair colours (fair, red, medium, dark, black).

**Source**

**References**

**Examples**

```r
  corresp(caith)
  dimnames(caith)[[2]] <- c("F", "R", "M", "D", "B")
  par(mfcol=c(1,3))
  plot(corresp(caith, nf=2)); title("symmetric")
  plot(corresp(caith, nf=2), type="rows"); title("rows")
  plot(corresp(caith, nf=2), type="col"); title("columns")
  par(mfrow=c(1,1))
```

---

### Cars93

**Data from 93 Cars on Sale in the USA in 1993**

**Description**

The Cars93 data frame has 93 rows and 27 columns.

**Usage**

Cars93
Format

This data frame contains the following columns:

- **Manufacturer** Manufacturer.
- **Model** Model.
- **Type** Type: a factor with levels "Small", "Sporty", "Compact", "Midsize", "Large" and "Van".
- **Min.Price** Minimum Price (in \$1,000): price for a basic version.
- **Price** Midrange Price (in \$1,000): average of Min.Price and Max.Price.
- **Max.Price** Maximum Price (in \$1,000): price for “a premium version”.
- **MPG.city** City MPG (miles per US gallon by EPA rating).
- **MPG.highway** Highway MPG.
- **AirBags** Air Bags standard. Factor: none, driver only, or driver & passenger.
- **DriveTrain** Drive train type: rear wheel, front wheel or 4WD; (factor).
- **Cylinders** Number of cylinders (missing for Mazda RX-7, which has a rotary engine).
- **EngineSize** Engine size (litres).
- **Horsepower** Horsepower (maximum).
- **RPM** RPM (revs per minute at maximum horsepower).
- **Rev.per.mile** Engine revolutions per mile (in highest gear).
- **Man.trans.avail** Is a manual transmission version available? (yes or no, Factor).
- **Fuel.tank.capacity** Fuel tank capacity (US gallons).
- **Passengers** Passenger capacity (persons)
- **Length** Length (inches).
- **Wheelbase** Wheelbase (inches).
- **Width** Width (inches).
- **Turn.circle** U-turn space (feet).
- **Rear.seat.room** Rear seat room (inches) (missing for 2-seater vehicles).
- **Luggage.room** Luggage capacity (cubic feet) (missing for vans).
- **Weight** Weight (pounds).
- **Origin** Of non-USA or USA company origins? (factor).
- **Make** Combination of Manufacturer and Model (character).

Details

Cars were selected at random from among 1993 passenger car models that were listed in both the Consumer Reports issue and the PACE Buying Guide. Pickup trucks and Sport/Utility vehicles were eliminated due to incomplete information in the Consumer Reports source. Duplicate models (e.g., Dodge Shadow and Plymouth Sundance) were listed at most once.

Further description can be found in Lock (1993).

Heat Evolved by Setting Cements

Description

Experiment on the heat evolved in the setting of each of 13 cements.

Usage
cement

Format

- **x1, x2, x3, x4**: Proportions (%) of active ingredients.
- **y**: Heat evolved in cals/gm.

Details

Thirteen samples of Portland cement were set. For each sample, the percentages of the four main chemical ingredients was accurately measured. While the cement was setting the amount of heat evolved was also measured.
Source

References

Examples

```r
lm(y ~ x1 + x2 + x3 + x4, cement)
```

chem Copper in Wholemeal Flour

Description

A numeric vector of 24 determinations of copper in wholemeal flour, in parts per million.

Usage

chem

Source

References

con2tr Convert Lists to Data Frames for use by lattice

Description

Convert lists to data frames for use by lattice.

Usage

con2tr(obj)

Arguments

obj A list of components x, y and z as passed to contour.

Details

con2tr repeats the x and y components suitably to match the vector z.
Value

A data frame suitable for passing to lattice (formerly trellis) functions.

References

Description

Computes confidence intervals for one or more parameters in a fitted model. Package MASS adds methods for glm and nls fits.

Usage

## S3 method for class 'glm'
confint(object, parm, level = 0.95, trace = FALSE, ...)

## S3 method for class 'nls'
confint(object, parm, level = 0.95, ...)

Arguments

object a fitted model object. Methods currently exist for the classes "glm", "nls" and for profile objects from these classes.

parm a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.

level the confidence level required.

trace logical. Should profiling be traced?

... additional argument(s) for methods.

Details

confint is a generic function in package stats.

These confint methods call the appropriate profile method, then find the confidence intervals by interpolation in the profile traces. If the profile object is already available it should be used as the main argument rather than the fitted model object itself.

Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1 - level)/2 and 1 - (1 - level)/2 in % (by default 2.5% and 97.5%).

References

contr.sdif

Examples

```r
expn1 <- deriv(y ~ b0 + b1 * 2^(-x/th), c("b0", "b1", "th"),
function(b0, b1, th, x) { })
wtloss.gr <- nls(Weight ~ expn1(b0, b1, th, Days),
  data = wtloss, start = c(b0=90, b1=95, th=120))
expn2 <- deriv(-b0 + b1*(w0 - b0)/b1)^*(x/d0),
c("b0","b1","d0"), function(b0, b1, d0, x, w0) { })
wtloss.init <- function(obj, w0) {
  p <- coef(obj)
  d0 <- - log((w0 - p["b0"])/p["b1"]) / log(2) * p["th"]
  c(p[c("b0", "b1")], d0 = as.vector(d0))
}
out <- NULL
w0s <- c(110, 100, 90)
for(w0 in w0s) {
  fm <- nls(Weight ~ expn2(b0, b1, d0, Days, w0),
    wtloss, start = wtloss.init(wtloss.gr, w0))
  out <- rbind(out, c(coef(fm)["d0"], confint(fm, "d0")))
}
dimnames(out) <- list(paste(w0s, "kg:"), c("d0", "low", "high"))
out
```

```r
dose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 8, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg0 <- glm(SF ~ sex + ldose - 1, family = binomial)
confint(budworm.lg0)
confint(budworm.lg0, "ldose")
```

contr.sdif

**Successive Differences Contrast Coding**

**Description**

A coding for factors based on successive differences.

**Usage**

```r
contr.sdif(n, contrasts = TRUE, sparse = FALSE)
```

**Arguments**

- `n` The number of levels required.
- `contrasts` logical: Should there be n - 1 columns orthogonal to the mean (the default) or n columns spanning the space?
sparse logical. If true and the result would be sparse (only true for contrasts = FALSE), return a sparse matrix.

Details

The contrast coefficients are chosen so that the coded coefficients in a one-way layout are the differences between the means of the second and first levels, the third and second levels, and so on. This makes most sense for ordered factors, but does not assume that the levels are equally spaced.

Value

If contrasts is TRUE, a matrix with n rows and n - 1 columns, and the n by n identity matrix if contrasts is FALSE.

chem, abbey.

corresp

Simple Correspondence Analysis

Description

Find the principal canonical correlation and corresponding row- and column-scores from a correspondence analysis of a two-way contingency table.

Usage

corresp(x, ...)

## S3 method for class 'matrix'
corresp(x, nf = 1, ...)

## S3 method for class 'factor'
corresp(x, y, ...)

## S3 method for class 'data.frame'
corresp(x, ...)

## S3 method for class 'xtabs'
corresp(x, ...)

## S3 method for class 'formula'
corresp(formula, data, ...)

Arguments

x, formula The function is generic, accepting various forms of the principal argument for specifying a two-way frequency table. Currently accepted forms are matrices, data frames (coerced to frequency tables), objects of class "xtabs" and formulae of the form ~ F1 + F2, where F1 and F2 are factors.

nf The number of factors to be computed. Note that although 1 is the most usual, one school of thought takes the first two singular vectors for a sort of biplot.

y a second factor for a cross-classification.

data a data frame against which to preferentially resolve variables in the formula.

... If the principal argument is a formula, a data frame may be specified as well from which variables in the formula are preferentially satisfied.
Details

See Venables & Ripley (2002). The plot method produces a graphical representation of the table if nf=1, with the areas of circles representing the numbers of points. If nf is two or more the biplot method is called, which plots the second and third columns of the matrices $A = Dr^*(-1/2) U L$ and $B = Dc^*(-1/2) V L$ where the singular value decomposition is $U L V$. Thus the x-axis is the canonical correlation times the row and column scores. Although this is called a biplot, it does not have any useful inner product relationship between the row and column scores. Think of this as an equally-scaled plot with two unrelated sets of labels. The origin is marked on the plot with a cross. (For other versions of this plot see the book.)

Value

An list object of class "correspondence" for which print, plot and biplot methods are supplied. The main components are the canonical correlation(s) and the row and column scores.

References

See Also

svd, princomp.

Examples

(c <- corresp(~ Age + Eth, data = quine))
plot(c)
corresp(caith)
biplot(corresp(caith, nf = 2))

Description

Compute a multivariate location and scale estimate with a high breakdown point – this can be thought of as estimating the mean and covariance of the good part of the data. cov.mve and cov.mcd are compatibility wrappers.

Usage

cov.rob(x, cor = FALSE, quantile.used = floor((n + p + 1)/2),
method = c("mve", "mcd", "classical"),
nsamp = "best", seed)
cov.mve(...)
cov.mcd(...)
Arguments

x a matrix or data frame.
cor should the returned result include a correlation matrix?
quantile.used the minimum number of the data points regarded as good points.
method the method to be used – minimum volume ellipsoid, minimum covariance determinant or classical product-moment. Using cov.mve or cov.mcd forces mve or mcd respectively.
nsamp the number of samples or "best" or "exact" or "sample". If "sample" the number chosen is \( \min(5p, 3000) \), taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples: if "exact" exhaustive enumeration will be attempted however many samples are needed.
seed the seed to be used for random sampling: see RNGkind. The current value of .Random.seed will be preserved if it is set.
... arguments to cov.rob other than method.

details

For method "mve", an approximate search is made of a subset of size quantile.used with an enclosing ellipsoid of smallest volume; in method "mcd" it is the volume of the Gaussian confidence ellipsoid, equivalently the determinant of the classical covariance matrix, that is minimized. The mean of the subset provides a first estimate of the location, and the rescaled covariance matrix a first estimate of scatter. The Mahalanobis distances of all the points from the location estimate for this covariance matrix are calculated, and those points within the 97.5% point under Gaussian assumptions are declared to be good. The final estimates are the mean and rescaled covariance of the good points.

The rescaling is by the appropriate percentile under Gaussian data; in addition the first covariance matrix has an ad hoc finite-sample correction given by Marazzi.

For method "mve" the search is made over ellipsoids determined by the covariance matrix of \( p \) of the data points. For method "mcd" an additional improvement step suggested by Rousseeuw and van Driessen (1999) is used, in which once a subset of size quantile.used is selected, an ellipsoid based on its covariance is tested (as this will have no larger a determinant, and may be smaller).

Value

A list with components

center the final estimate of location.
cov the final estimate of scatter.
cor (only is cor = TRUE) the estimate of the correlation matrix.
sing message giving number of singular samples out of total
crit the value of the criterion on log scale. For MCD this is the determinant, and for MVE it is proportional to the volume.
best the subset used. For MVE the best sample, for MCD the best set of size quantile.used.
n.obs total number of observations.

cov.rob(stackloss)
cov.rob(stack.x, method = "mcd", nsamp = "exact")
```

---

cov.trob

*Covariance Estimation for Multivariate t Distribution*

Description

Estimates a covariance or correlation matrix assuming the data came from a multivariate t distribution: this provides some degree of robustness to outlier without giving a high breakdown point.

Usage

```r
cov.trob(x, wt = rep(1, n), cor = FALSE, center = TRUE, nu = 5,
          maxit = 25, tol = 0.01)
```

Arguments

- `x`: data matrix. Missing values (NAs) are not allowed.
- `wt`: A vector of weights for each case: these are treated as if the case `i` actually occurred `wt[i]` times.
- `cor`: Flag to choose between returning the correlation (`cor = TRUE`) or covariance (`cor = FALSE`) matrix.
- `center`: a logical value or a numeric vector providing the location about which the covariance is to be taken. If `center = FALSE`, no centering is done; if `center = TRUE` the MLE of the location vector is used.
- `nu`: ‘degrees of freedom’ for the multivariate t distribution. Must exceed 2 (so that the covariance matrix is finite).
- `maxit`: Maximum number of iterations in fitting.
- `tol`: Convergence tolerance for fitting.
Value

A list with the following components

- **cov**: the fitted covariance matrix.
- **center**: the estimated or specified location vector.
- **wt**: the specified weights: only returned if the `wt` argument was given.
- **n.obs**: the number of cases used in the fitting.
- **cor**: the fitted correlation matrix: only returned if `cor = TRUE`.
- **call**: The matched call.
- **iter**: The number of iterations used.

References

- `cov`, `cov.wt`, `cov.mve`

Examples

```r
cov.trob(stackloss)
```

### cpus

**Performance of Computer CPUs**

Description

A relative performance measure and characteristics of 209 CPUs.

Usage

`cpus`

Format

The components are:

- **name**: manufacturer and model.
- **syct**: cycle time in nanoseconds.
- **mmin**: minimum main memory in kilobytes.
- **mmax**: maximum main memory in kilobytes.
- **cach**: cache size in kilobytes.
- **chmin**: minimum number of channels.
- **chmax**: maximum number of channels.
- **perf**: published performance on a benchmark mix relative to an IBM 370/158-3.
- **estperf**: estimated performance (by Ein-Dor & Feldmesser).
The `crabs` data frame has 200 rows and 8 columns, describing 5 morphological measurements on 50 crabs each of two colour forms and both sexes, of the species *Leptograpsus variegatus* collected at Fremantle, W. Australia.

### Usage

`crabs`

### Format

This data frame contains the following columns:

- `sp` species: "B" or "O" for blue or orange.
- `sex` as it says.
- `index` index 1:50 within each of the four groups.
- `FL` frontal lobe size (mm).
- `RW` rear width (mm).
- `CL` carapace length (mm).
- `CW` carapace width (mm).
- `BD` body depth (mm).

Cushings

Diagnostic Tests on Patients with Cushing's Syndrome

Description
Cushing's syndrome is a hypertensive disorder associated with over-secretion of cortisol by the adrenal gland. The observations are urinary excretion rates of two steroid metabolites.

Usage
Cushings

Format
The Cushings data frame has 27 rows and 3 columns:
- Tetrahydrocortisone urinary excretion rate (mg/24hr) of Tetrahydrocortisone.
- Pregnanetriol urinary excretion rate (mg/24hr) of Pregnanetriol.
- Type underlying type of syndrome, coded a (adenoma), b (bilateral hyperplasia), c (carcinoma) or u for unknown.

This the same as dataset `deaths` in R’s `datasets` package.

denumerate

Description
`loglm` allows dimension numbers to be used in place of names in the formula. `denumerate` modifies such a formula into one that `terms` can process.

Usage
denumerate(x)

Arguments
x
A formula conforming to the conventions of `loglm`, that is, it may allow dimension numbers to stand in for names when specifying a log-linear model.

Details
The model fitting function `loglm` fits log-linear models to frequency data using iterative proportional scaling. To specify the model the user must nominate the margins in the data that remain fixed under the log-linear model. It is convenient to allow the user to use dimension numbers, 1, 2, 3, ... for the first, second, third, ..., margins in a similar way to variable names. As the model formula has to be parsed by `terms`, which treats 1 in a special way and requires parseable variable names, these formulae have to be modified by giving genuine names for these margin, or dimension numbers. `denumerate` replaces these numbers with names of a special form, namely `n` is replaced by `.vn`. This allows `terms` to parse the formula in the usual way.
Value

A linear model formula like that presented, except that where dimension numbers, say n, have been used to specify fixed margins these are replaced by names of the form .vn which may be processed by terms.

renumerate

Examples

denumerate(~(1+2+3)*3 + a/b)
## which gives ~ (.v1 + .v2 + .v3)^3 + a/b

dose.p

Predict Doses for Binomial Assay model

Description

Calibrate binomial assays, generalizing the calculation of LD50.

Usage

dose.p(obj, cf = 1:2, p = 0.5)

Arguments

obj

A fitted model object of class inheriting from "glm".

cf

The terms in the coefficient vector giving the intercept and coefficient of (log-)
dose

p

Probabilities at which to predict the dose needed.

Value

An object of class "glm.dose" giving the prediction (attribute "p" and standard error (attribute "SE") at each response probability.

References

Examples

ldose <- rep(0:5, 2)
umdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg0 <- glm(SF ~ sex + ldose - 1, family = binomial)
dose.p(budworm.lg0, cf = c(1,3), p = 1:3/4)
dose.p(update(budworm.lg0, family = binomial(link=probit)),
   cf = c(1,3), p = 1:3/4)
## drivers

*Deaths of Car Drivers in Great Britain 1969-84*

**Description**

A regular time series giving the monthly totals of car drivers in Great Britain killed or seriously injured Jan 1969 to Dec 1984. Compulsory wearing of seat belts was introduced on 31 Jan 1983.

**Usage**

`drivers`

**Source**

**References**

## dropterm

*Try All One-Term Deletions from a Model*

**Description**

Try fitting all models that differ from the current model by dropping a single term, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

**Usage**

`dropterm(object, ...)`

```r
## Default S3 method:
dropterm(object, scope, scale = 0, test = c("none", "Chisq"),
  k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'lm'
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
  k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'glm'
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
  k = 2, sorted = FALSE, trace = FALSE, ...)
```
Arguments

object  A object fitted by some model-fitting function.
scope   a formula giving terms which might be dropped. By default, the model formula. Only terms that can be dropped and maintain marginality are actually tried.
scale   used in the definition of the AIC statistic for selecting the models, currently only for lm, aov and glm models. Specifying scale asserts that the residual standard error or dispersion is known.
test    should the results include a test statistic relative to the original model? The F test is only appropriate for lm and aov models, and perhaps for some over-dispersed glm models. The Chisq test can be an exact test (lm models with known scale) or a likelihood-ratio test depending on the method.
k      the multiple of the number of degrees of freedom used for the penalty. Only k = 2 gives the genuine AIC: k = log(n) is sometimes referred to as BIC or SBC.
sorted  should the results be sorted on the value of AIC?
trace   if TRUE additional information may be given on the fits as they are tried.
...    arguments passed to or from other methods.

Details

The definition of AIC is only up to an additive constant: when appropriate (lm models with specified scale) the constant is taken to be that used in Mallows’ Cp statistic and the results are labelled accordingly.

Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

Foraging Ecology of Bald Eagles

Description

Knight and Skagen collected during a field study on the foraging behaviour of wintering Bald Eagles in Washington State, USA data concerning 160 attempts by one (pirating) Bald Eagle to steal a chum salmon from another (feeding) Bald Eagle.

Usage

eagles

Format

The eagles data frame has 8 rows and 5 columns.

y Number of successful attempts.
n Total number of attempts.
P Size of pirating eagle (L = large, S = small).
A Age of pirating eagle (I = immature, A = adult).
V Size of victim eagle (L = large, S = small).

Seizure Counts for Epileptics

Description

Thall and Vail (1990) give a data set on two-week seizure counts for 59 epileptics. The number of seizures was recorded for a baseline period of 8 weeks, and then patients were randomly assigned to a treatment group or a control group. Counts were then recorded for four successive two-week periods. The subject’s age is the only covariate.

Usage

epil

Format

This data frame has 236 rows and the following 9 columns:

- y: the count for the 2-week period.
- trt: treatment, "placebo" or "progabide".
- base: the counts in the baseline 8-week period.
- age: subject’s age, in years.
- V4: 0/1 indicator variable of period 4.
- subject: subject number, 1 to 59.
- period: period, 1 to 4.
- 1base: log-counts for the baseline period, centred to have zero mean.
- 1age: log-ages, centred to have zero mean.

Source

Plots with Geometrically Equal Scales

Description

Version of a scatterplot with scales chosen to be equal on both axes, that is 1cm represents the same units on each axis.

Usage

eqscplot(x, y, ratio = 1, tol = 0.04, uin, ...)

Arguments

x vector of x values, or a 2-column matrix, or a list with components x and y
y vector of y values
ratio desired ratio of units on the axes. Units on the y axis are drawn at ratio times the size of units on the x axis. Ignored if uin is specified and of length 2.
tol proportion of white space at the margins of plot
uin desired values for the units-per-inch parameter. If of length 1, the desired units per inch on the x axis.
... further arguments for plot and graphical parameters. Note that par(xaxs="i", yaxs="i") is enforced, and xlim and ylim will be adjusted accordingly.

Details

Limits for the x and y axes are chosen so that they include the data. One of the sets of limits is then stretched from the midpoint to make the units in the ratio given by ratio. Finally both are stretched by 1 + tol to move points away from the axes, and the points plotted.

Value

invisibly, the values of uin used for the plot.

Side Effects

performs the plot.
farms

Note
Arguments ratio and uin were suggested by Bill Dunlap.

farms

Ecological Factors in Farm Management

Description
The farms data frame has 20 rows and 4 columns. The rows are farms on the Dutch island of Terschelling and the columns are factors describing the management of grassland.

Usage
farms

Format
This data frame contains the following columns:
- **Mois** Five levels of soil moisture – level 3 does not occur at these 20 farms.
- **Manag** Grassland management type (SF = standard, BF = biological, HF = hobby farming, NM = nature conservation).
- **Use** Grassland use (U1 = hay production, U2 = intermediate, U3 = grazing).
- **Manure** Manure usage – classes C0 to C4.

```
**fg1**

*Measurements of Forensic Glass Fragments*

**Description**

The `fg1` data frame has 214 rows and 10 columns. It was collected by B. German on fragments of glass collected in forensic work.

**Usage**

`fg1`

**Format**

This data frame contains the following columns:

- **RI** refractive index; more precisely the refractive index is 1.518xxxx.
- The next 8 measurements are percentages by weight of oxides:
  - **Na** sodium.
  - **Mg** manganese.
  - **Al** aluminium.
  - **Si** silicon.
  - **K** potassium.
  - **Ca** calcium.
  - **Ba** barium.
  - **Fe** iron.
- **type** The fragments were originally classed into seven types, one of which was absent in this dataset. The categories which occur are window float glass (**winf**: 70), window non-float glass (**winnf**: 76), vehicle window glass (**veh**: 17), containers (**con**: 13), tableware (**tabl**: 9) and vehicle headlamps (**head**: 29).

**References**

---

**fitdistr**

*Maximum-likelihood Fitting of Univariate Distributions*

**Description**

Maximum-likelihood fitting of univariate distributions, allowing parameters to be held fixed if desired.

**Usage**

`fitdistr(x, densfun, start, ...)`
Arguments

- **x**: A numeric vector of length at least one containing only finite values.

- **densfun**: Either a character string or a function returning a density evaluated at its first argument. Distributions "beta", "cauchy", "chi-squared", "exponential", "f", "gamma", "geometric", "log-normal", "lognormal", "logistic", "negative binomial", "normal", "Poisson", "t" and "weibull" are recognised, case being ignored.

- **start**: A named list giving the parameters to be optimized with initial values. This can be omitted for some of the named distributions and must be for others (see Details).

- **...**: Additional parameters, either for densfun or for optim. In particular, it can be used to specify bounds via lower or upper or both. If arguments of densfun (or the density function corresponding to a character-string specification) are included they will be held fixed.

Details

For the Normal, log-Normal, geometric, exponential and Poisson distributions the closed-form MLEs (and exact standard errors) are used, and start should not be supplied.

For all other distributions, direct optimization of the log-likelihood is performed using optim. The estimated standard errors are taken from the observed information matrix, calculated by a numerical approximation. For one-dimensional problems the Nelder-Mead method is used and for multi-dimensional problems the BFGS method, unless arguments named lower or upper are supplied (when L-BFGS-B is used) or method is supplied explicitly.

For the "t" named distribution the density is taken to be the location-scale family with location \(m\) and scale \(s\).

For the following named distributions, reasonable starting values will be computed if start is omitted or only partially specified: "cauchy", "gamma", "logistic", "negative binomial" (parametrized by mu and size), "t" and "weibull". Note that these starting values may not be good enough if the fit is poor: in particular they are not resistant to outliers unless the fitted distribution is long-tailed.

There are print, coef, vcov and logLik methods for class "fitdistr".

Value

An object of class "fitdistr", a list with four components,

- **estimate**: the parameter estimates,
- **sd**: the estimated standard errors,
- **vcov**: the estimated variance-covariance matrix, and
- **loglik**: the log-likelihood.

Note

Numerical optimization cannot work miracles: please note the comments in optim on scaling data. If the fitted parameters are far away from one, consider re-fitting specifying the control parameter parscale.
## References

## forbes

*Forbes’ Data on Boiling Points in the Alps*

### Description

A data frame with 17 observations on boiling point of water and barometric pressure in inches of mercury.

### Usage

```r
forbes
```

### Format

- **bp**: boiling point (degrees Fahrenheit).
- **pres**: barometric pressure in inches of mercury.

### Source

**fractions**

**Rational Approximation**

**Description**

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

**Usage**

fractions(x, cycles = 10, max.denominator = 2000, ...)

**Arguments**

- **x**: Any object of mode numeric. Missing values are now allowed.
- **cycles**: The maximum number of steps to be used in the continued fraction approximation process.
- **max.denominator**: An early termination criterion. If any partial denominator exceeds max.denominator the continued fraction stops at that point.
- **...**: arguments passed to or from other methods.

**Details**

Each component is first expanded in a continued fraction of the form

\[ x = \text{floor}(x) + \frac{1}{p_1 + \frac{1}{p_2 + \ldots}} \]

where \( p_1, p_2, \ldots \) are positive integers, terminating either at cycles terms or when a \( p_j > \) max.denominator. The continued fraction is then re-arranged to retrieve the numerator and denominator as integers.

The numerators and denominators are then combined into a character vector that becomes the "fracs" attribute and used in printed representations.

Arithmetic operations on "fractions" objects have full floating point accuracy, but the character representation printed out may not.

**Value**

An object of class "fractions". A structure with .Data component the same as the input numeric x, but with the rational approximations held as a character vector attribute, "fracs". Arithmetic operations on "fractions" objects are possible.

```
  gamma.dispersion
```

*Calculate the MLE of the Gamma Dispersion Parameter in a GLM Fit*

Description

A front end to `gamma.shape` for convenience. Finds the reciprocal of the estimate of the shape parameter only.

Usage

```
  gamma.dispersion(object, ...)      
```

Arguments

- **object**: Fitted model object giving the gamma fit.
- **...**: Additional arguments passed on to `gamma.shape`.

Value

The MLE of the dispersion parameter of the gamma distribution.

References

gamma.shape

Estimate the Shape Parameter of the Gamma Distribution in a GLM Fit

Description

Find the maximum likelihood estimate of the shape parameter of the gamma distribution after fitting a Gamma generalized linear model.

Usage

```r
## S3 method for class 'glm'
gamma.shape(object, it.lim = 10,
    eps.max = .Machine$double.eps^0.25, verbose = FALSE, ...)
```

Arguments

- `object`: Fitted model object from a Gamma family or quasi family with variance = \( \mu^2 \).
- `it.lim`: Upper limit on the number of iterations.
- `eps.max`: Maximum discrepancy between approximations for the iteration process to continue.
- `verbose`: If TRUE, causes successive iterations to be printed out. The initial estimate is taken from the deviance.
- `...`: further arguments passed to or from other methods.

Details

A glm fit for a Gamma family correctly calculates the maximum likelihood estimate of the mean parameters but provides only a crude estimate of the dispersion parameter. This function takes the results of the glm fit and solves the maximum likelihood equation for the reciprocal of the dispersion parameter, which is usually called the shape (or exponent) parameter.

Value

List of two components

- `alpha`: the maximum likelihood estimate
- `SE`: the approximate standard error, the square-root of the reciprocal of the observed information.

### Old Faithful Geyser Data

**Description**

A version of the eruptions data from the ‘Old Faithful’ geyser in Yellowstone National Park, Wyoming. This version comes from Azzalini and Bowman (1990) and is of continuous measurement from August 1 to August 15, 1985.

Some nocturnal duration measurements were coded as 2, 3 or 4 minutes, having originally been described as ‘short’, ‘medium’ or ‘long’.

**Usage**

geyser

**Format**

A data frame with 299 observations on 2 variables.

- **duration**: numeric  Eruption time in mins
- **waiting**: numeric  Waiting time for this eruption

**Note**

The `waiting` time was incorrectly described as the time to the next eruption in the original files, and corrected for MASS version 7.3-30.

**References**

### Line Transect of Soil in Gilgai Territory

**Description**

This dataset was collected on a line transect survey in gilgai territory in New South Wales, Australia. Gilgais are natural gentle depressions in otherwise flat land, and sometimes seem to be regularly distributed. The data collection was stimulated by the question: are these patterns reflected in soil properties? At each of 365 sampling locations on a linear grid of 4 meters spacing, samples were taken at depths 0-10 cm, 30-40 cm and 80-90 cm below the surface. pH, electrical conductivity and chloride content were measured on a 1:5 soil:water extract from each sample.
Usage
gilgais

Format
This data frame contains the following columns:

- pH0: pH at depth 0–10 cm.
- pH3: pH at depth 30–40 cm.
- pH8: pH at depth 80–90 cm.
- e0: electrical conductivity in mS/cm (0–10 cm).
- e3: electrical conductivity in mS/cm (30–40 cm).
- e8: electrical conductivity in mS/cm (80–90 cm).
- c0: chloride content in ppm (0–10 cm).
- c3: chloride content in ppm (30–40 cm).
- c8: chloride content in ppm (80–90 cm).

*Generalized Inverse of a Matrix*

Description
Calculates the Moore-Penrose generalized inverse of a matrix $X$.

Usage

```r
ginv(X, tol = sqrt(.Machine$double.eps))
```

Arguments

- **X**: Matrix for which the Moore-Penrose inverse is required.
- **tol**: A relative tolerance to detect zero singular values.

Value
A MP generalized inverse matrix for $X$. 

References

See Also

solve, svd, eigen

Examples

## Not run:
# The function is currently defined as
function(X, tol = sqrt(.Machine$double.eps))
{
  ## Generalized Inverse of a Matrix
  dnx <- dimnames(X)
  if(is.null(dnx)) dnx <- vector("list", 2)
  s <- svd(X)
  nz <- s$d > tol * s$d[1]
  structure(
    if(any(nz)) $v[, nz] %*% (t(s$u[, nz])/s$d[nz]) else X,
    dimnames = dnx[2:1])
}
## End(Not run)
```

glm.convert

Change a Negative Binomial fit to a GLM fit

Description

This function modifies an output object from glm.nb() to one that looks like the output from glm() with a negative binomial family. This allows it to be updated keeping the theta parameter fixed.

Usage

glm.convert(object)

Arguments

object An object of class "negbin", typically the output from glm.nb().

Details

Convenience function needed to effect some low level changes to the structure of the fitted model object.

Value

An object of class "glm" with negative binomial family. The theta parameter is then fixed at its present estimate.
See Also

`glm.nb`, `negative.binomial.glm`

Examples

```r
quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nbA <- glm.convert(quine.nb1)
quine.nbB <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
anova(quine.nbA, quine.nbB)
```

---

**glm.nb**

**Fit a Negative Binomial Generalized Linear Model**

**Description**

A modification of the system function `glm()` to include estimation of the additional parameter, theta, for a Negative Binomial generalized linear model.

**Usage**

```r
glm.nb(formula, data, weights, subset, na.action, 
       start = NULL, etastart, mustart, 
       control = glm.control(...), method = "glm.fit", 
       model = TRUE, x = FALSE, y = TRUE, contrasts = NULL, ..., 
       init.theta, link = log)
```

**Arguments**

- `formula`, `data`, `weights`, `subset`, `na.action`, `start`, `etastart`, `mustart`, `control`, `method`, `model`, `x`, arguments for the `glm()` function. Note that these exclude family and offset (but `offset()` can be used).
- `init.theta` Optional initial value for the theta parameter. If omitted a moment estimator after an initial fit using a Poisson GLM is used.
- `link` The link function. Currently must be one of `log`, `sqrt` or `identity`.

**Details**

An alternating iteration process is used. For given theta the GLM is fitted using the same process as used by `glm()`. For fixed means the theta parameter is estimated using score and information iterations. The two are alternated until convergence of both. (The number of alternations and the number of iterations when estimating theta are controlled by the `maxit` parameter of `glm.control`.)

Setting `trace > 0` traces the alternating iteration process. Setting `trace > 1` traces the `glm` fit, and setting `trace > 2` traces the estimation of theta.

**Value**

A fitted model object of class `negbin` inheriting from `glm` and `lm`. The object is like the output of `glm` but contains three additional components, namely `theta` for the ML estimate of theta, `SE.theta` for its approximate standard error (using observed rather than expected information), and `twologlik` for twice the log-likelihood function.

There is a simulate method.

Examples

quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nb2 <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
quine.nb3 <- update(quine.nb2, Days ~ .^4)
anova(quine.nb1, quine.nb2, quine.nb3)

glmmPQL

Fit Generalized Linear Mixed Models via PQL

Description

Fit a GLMM model with multivariate normal random effects, using Penalized Quasi-Likelihood.

Usage

glmmPQL(fixed, random, family, data, correlation, weights,
control, niter = 10, verbose = TRUE, ...)

Arguments

fixed
random
family
data
correlation
weights
control
niter
verbose
...

a two-sided linear formula giving fixed-effects part of the model.
a formula or list of formulae describing the random effects.
a GLM family.
an optional data frame used as the first place to find variables in the formulae,
weights and if present in ..., subset.
an optional correlation structure.
optional case weights as in glm.
an optional argument to be passed to lme.
maximum number of iterations.
logical: print out record of iterations?
Further arguments for lme.

Details

glmmPQL works by repeated calls to lme, so package nlme will be loaded at first use if necessary.

Value

A object of class "lme": see lmeObject.
1970

References

See Also

`lm`""

Examples

```r
library(nlme) # will be loaded automatically if omitted
summary(glmPQL(y ~ trt + I(week > 2), random = ~ 1 | ID,
    family = binomial, data = bacteria))
```

hills  

*Record Times in Scottish Hill Races*

Description

The record times in 1984 for 35 Scottish hill races.

Usage

hills

Format

The components are:

dist  distance in miles (on the map).
climb  total height gained during the route, in feet.
time  record time in minutes.

Source

[A.C. Atkinson (1988) Transformations unmasked. *Technometrics* **30**, 311–318 “corrects” the time for Knock Hill from 78.65 to 18.65. It is unclear if this based on the original records.]

References

**hist.scott**

**Plot a Histogram with Automatic Bin Width Selection**

**Description**

Plot a histogram with automatic bin width selection, using the Scott or Freedman–Diaconis formulae.

**Usage**

```r
hist.scott(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
hist.FD(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
```

**Arguments**

- `x` A data vector
- `prob` Should the plot have unit area, so be a density estimate?
- `xlab, ...` Further arguments to `hist`.

**Value**

For the `nclass.*` functions, the suggested number of classes.

**Side Effects**

Plot a histogram.

_Huber M-estimator of Location with MAD Scale_

**Description**

Finds the Huber M-estimator of location with MAD scale.

**Usage**

`huber(y, k = 1.5, tol = 1e-06)`

**Arguments**

- `y` vector of data values
- `k` Winsorizes at k standard deviations
- `tol` convergence tolerance

**Value**

- list of location and scale parameters
  - `mu` location estimate
  - `s` MAD scale estimate

*Huber Proposal 2 Robust Estimator of Location and/or Scale*

Description

Finds the Huber M-estimator for location with scale specified, scale with location specified, or both if neither is specified.

Usage

`hubers(y, k = 1.5, mu, s, initmu = median(y), tol = 1e-06)`

Arguments

- `y` vector of data values
- `k` Winsorizes at `k` standard deviations
- `mu` specified location
- `s` specified scale
- `initmu` initial value of `mu`
- `tol` convergence tolerance

Value

list of location and scale estimates

- `mu` location estimate
- `s` scale estimate

### Yields from a Barley Field Trial

### Description

The `immer` data frame has 30 rows and 4 columns. Five varieties of barley were grown in six locations in each of 1931 and 1932.

### Usage

`immer`

### Format

This data frame contains the following columns:

- **Loc**: The location.
- **Var**: The variety of barley ("manchuria", "svansota", "velvet", "trebi" and "peatland").
- **Y1**: Yield in 1931.
- **Y2**: Yield in 1932.

### Source

### References

### Examples

```r
immer.aov <- aov(cbind(Y1,Y2) ~ Loc + Var, data = immer)
summary(immer.aov)

immer.aov <- aov(((Y1+Y2)/2 ~ Var + Loc, data = immer)
summary(immer.aov)
model.tables(immer.aov, type = "means", se = TRUE, cterms = "Var")
```
Insurance

Numbers of Car Insurance claims

Description
The data given in data frame Insurance consist of the numbers of policyholders of an insurance company who were exposed to risk, and the numbers of car insurance claims made by those policyholders in the third quarter of 1973.

Usage
Insurance

Format
This data frame contains the following columns:

District factor: district of residence of policyholder (1 to 4): 4 is major cities.
Group an ordered factor: group of car with levels <1 litre, 1–1.5 litre, 1.5–2 litre, >2 litre.
Age an ordered factor: the age of the insured in 4 groups labelled <25, 25–29, 30–35, >35.
Holders numbers of policyholders.
Claims numbers of claims

Source

References

Examples
```r
## main-effects fit as Poisson GLM with offset
glm(Claims ~ District + Group + Age + offset(log(Holders)),
   data = Insurance, family = poisson)
# same via loglm
loglm(Claims ~ District + Group + Age + offset(log(Holders)),
      data = Insurance)
```
isoMDS

Kruskal's Non-metric Multidimensional Scaling

Description

One form of non-metric multidimensional scaling

Usage

isoMDS(d, y = cmdscale(d, k), k = 2, maxit = 50, trace = TRUE,
tol = 1e-3, p = 2)

Shepard(d, x, p = 2)

Arguments

d  distance structure of the form returned by dist, or a full, symmetric matrix.
   Data are assumed to be dissimilarities or relative distances, but must be positive
   except for self-distance. Both missing and infinite values are allowed.
y  An initial configuration. If none is supplied, cmdscale is used to provide the
   classical solution, unless there are missing or infinite dissimilarities.
k  The desired dimension for the solution, passed to cmdscale.
maxit  The maximum number of iterations.
trace  Logical for tracing optimization. Default TRUE.
tol  convergence tolerance.
p  Power for Minkowski distance in the configuration space.
x  A final configuration.

Details

This chooses a k-dimensional (default k = 2) configuration to minimize the stress, the square root of
the ratio of the sum of squared differences between the input distances and those of the configuration
the sum of configuration distances squared. However, the input distances are allowed a monotonic
transformation.

An iterative algorithm is used, which will usually converge in around 10 iterations. As this is
necessarily an $O(n^2)$ calculation, it is slow for large datasets. Further, since for the default $p = 2$
the configuration is only determined up to rotations and reflections (by convention the centroid is at
the origin), the result can vary considerably from machine to machine.

Value

Two components:

points  A k-column vector of the fitted configuration.
stress  The final stress achieved (in percent).

Side Effects

If trace is true, the initial stress and the current stress are printed out every 5 iterations.

**kde2d**

*Two-Dimensional Kernel Density Estimation*

Description

Two-dimensional kernel density estimation with an axis-aligned bivariate normal kernel, evaluated on a square grid.

Usage

```r
kde2d(x, y, h, n = 25, lims = c(range(x), range(y)))
```

Arguments

- `x` x coordinate of data
- `y` y coordinate of data
- `h` vector of bandwidths for x and y directions. Defaults to normal reference bandwidth (see `bandwidth.nrd`). A scalar value will be taken to apply to both directions.
- `n` Number of grid points in each direction. Can be scalar or a length-2 integer vector.
- `lims` The limits of the rectangle covered by the grid as `c(x1, xu, y1, yu)`.

Value

A list of three components.

- `x`, `y` The x and y coordinates of the grid points, vectors of length n.
References

Examples

```r
attach(geyser)
plot(duration, waiting, xlim = c(0.5, 6), ylim = c(40, 100))
f1 <- kde2d(duration, waiting, n = 50, lims = c(0.5, 6, 40, 100))
image(f1, zlim = c(0, 0.05))
f2 <- kde2d(duration, waiting, n = 50, lims = c(0.5, 6, 40, 100),
          h = c(width.SJ(duration), width.SJ(waiting)))
image(f2, zlim = c(0, 0.05))
persp(f2, phi = 30, theta = 20, d = 5)
plot(duration[-272], duration[-1], xlim = c(0.5, 6),
     ylim = c(1, 6), xlab = "previous duration", ylab = "duration")
f1 <- kde2d(duration[-272], duration[-1],
             h = rep(1.5, 2), n = 50, lims = c(0.5, 6, 0.5, 6))
contour(f1, xlab = "previous duration",
        ylab = "duration", levels = c(0.05, 0.1, 0.2, 0.4))
f1 <- kde2d(duration[-272], duration[-1],
             h = rep(0.6, 2), n = 50, lims = c(0.5, 6, 0.5, 6))
contour(f1, xlab = "previous duration",
        ylab = "duration", levels = c(0.05, 0.1, 0.2, 0.4))
f1 <- kde2d(duration[-272], duration[-1],
             h = rep(0.4, 2), n = 50, lims = c(0.5, 6, 0.5, 6))
contour(f1, xlab = "previous duration",
        ylab = "duration", levels = c(0.05, 0.1, 0.2, 0.4))
detach("geyser")
```

### lda

**Linear Discriminant Analysis**

**Description**

Linear discriminant analysis.

**Usage**

```r
lda(x, ...)  
## S3 method for class 'formula'
lda(formula, data, ..., subset, na.action)  
## Default S3 method:
lda(x, grouping, prior = proportions, tol = 1.0e-4,
    method, CV = FALSE, nu, ...)  
## S3 method for class 'data.frame'
lda(x, ...)  
## S3 method for class 'matrix'
lda(x, grouping, ..., subset, na.action)
```
Arguments

formula A formula of the form groups ~ x1 + x2 + ... That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.
data Data frame from which variables specified in formula are preferentially to be taken.
x (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.
grouping (required if no formula principal argument is given.) a factor specifying the class for each observation.
prior the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If present, the probabilities should be specified in the order of the factor levels.
tol A tolerance to decide if a matrix is singular; it will reject variables and linear combinations of unit-variance variables whose variance is less than tol^2.
subset An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
na.action A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is na.omit, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
method "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use cov.mve, or "t" for robust estimates based on a t distribution.
CV If true, returns results (classes and posterior probabilities) for leave-one-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.
u degrees of freedom for method = "t".
... arguments passed to or from other methods.

Details

The function tries hard to detect if the within-class covariance matrix is singular. If any variable has within-group variance less than tol^2 it will stop and report the variable as constant. This could result from poor scaling of the problem, but is more likely to result from constant variables.

Specifying the prior will affect the classification unless over-ridden in predict.lda. Unlike in most statistical packages, it will also affect the rotation of the linear discriminants within their space, as a weighted between-groups covariance matrix is used. Thus the first few linear discriminants emphasize the differences between groups with the weights given by the prior, which may differ from their prevalence in the dataset.

If one or more groups is missing in the supplied data, they are dropped with a warning, but the classifications produced are with respect to the original set of levels.

Value

If CV = TRUE the return value is a list with components class, the MAP classification (a factor), and posterior, posterior probabilities for the classes.

Otherwise it is an object of class "lda" containing the following components:

prior the prior probabilities used.
Idahist

means
the group means.
scaling
a matrix which transforms observations to discriminant functions, normalized so that within groups covariance matrix is spherical.
svd
the singular values, which give the ratio of the between- and within-group standard deviations on the linear discriminant variables. Their squares are the canonical F-statistics.
N
The number of observations used.
call
The (matched) function call.

Note
This function may be called giving either a formula and optional data frame, or a matrix and grouping factor as the first two arguments. All other arguments are optional, but subset= and na.action=, if required, must be fully named.

If a formula is given as the principal argument the object may be modified using update() in the usual way.

Idahist

Histograms or Density Plots of Multiple Groups

Description
Plot histograms or density plots of data on a single Fisher linear discriminant.
Usage

`ldahist(data, g, nbins = 25, h, x0 = - h/1000, breaks,`  
`xlim = range(breaks), ymax = 0, width,`  
`type = c("histogram", "density", "both"),`  
`sep = (type != "density"),`  
`col = 5, xlab = deparse(substitute(data)), bty = "n", ...)`

Arguments

- **data**: vector of data. Missing values (NAs) are allowed and omitted.
- **g**: factor or vector giving groups, of the same length as `data`.
- **nbins**: Suggested number of bins to cover the whole range of the data.
- **h**: The bin width (takes precedence over `nbins`).
- **x0**: Shift for the bins - the breaks are at `x0 + h * (..., -1, 0, 1, ...)`
- **breaks**: The set of breakpoints to be used. (Usually omitted, takes precedence over `h` and `nbins`).
- **xlim**: The limits for the x-axis.
- **ymax**: The upper limit for the y-axis.
- **width**: Bandwidth for density estimates. If missing, the Sheather-Jones selector is used for each group separately.
- **type**: Type of plot.
- **sep**: Whether there is a separate plot for each group, or one combined plot.
- **col**: The colour number for the bar fill.
- **xlab**: label for the plot x-axis. By default, this will be the name of `data`.
- **bty**: The box type for the plot - defaults to none.
- **...**: additional arguments to `polygon`.

Side Effects

Histogram and/or density plots are plotted on the current device.

References

See Also

`plot.lda`. 
Description

A data frame of data from 33 leukaemia patients.

Usage

leuk

Format

A data frame with columns:

- **wbc**: white blood count.
- **ag**: a test result, "present" or "absent".
- **time**: survival time in weeks.

Details

Survival times are given for 33 patients who died from acute myelogenous leukaemia. Also measured was the patient’s white blood cell count at the time of diagnosis. The patients were also factored into 2 groups according to the presence or absence of a morphologic characteristic of white blood cells. Patients termed AG positive were identified by the presence of Auer rods and/or significant granulation of the leukaemic cells in the bone marrow at the time of diagnosis.

Source

Taken from

References

Examples

```r
library(survival)
plot(survfit(Surv(time) ~ ag, data = leuk), lty = 2:3, col = 2:3)

# now Cox models
leuk.cox <- coxph(Surv(time) ~ ag + log(wbc), leuk)
summary(leuk.cox)
```
**Description**

Fit linear models by Generalized Least Squares

**Usage**

```r
dl.gls(formula, data, W, subset, na.action, inverse = FALSE,
       method = "qr", model = FALSE, x = FALSE, y = FALSE,
       contrasts = NULL, ...)
```

**Arguments**

- `formula`: a formula expression as for regression models, of the form `response ~ predictors`. See the documentation of `formula` for other details.
- `data`: an optional data frame in which to interpret the variables occurring in `formula`.
- `W`: a weight matrix.
- `subset`: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
- `na.action`: a function to filter missing data.
- `inverse`: logical: if true `W` specifies the inverse of the weight matrix: this is appropriate if a variance matrix is used.
- `method`: method to be used by `lm.fit`.
- `model`: should the model frame be returned?
- `x`: should the design matrix be returned?
- `y`: should the response be returned?
- `contrasts`: a list of contrasts to be used for some or all of
- `...`: additional arguments to `lm.fit`.

**Details**

The problem is transformed to uncorrelated form and passed to `lm.fit`.

**Value**

An object of class "lm.gls", which is similar to an "lm" object. There is no "weights" component, and only a few "lm" methods will work correctly. As from version 7.1-22 the residuals and fitted values refer to the untransformed problem.

**See Also**

`gls`, `lm`, `lm.ridge`
lm.ridge

Description

Fit a linear model by ridge regression.

Usage

```r
lm.ridge(formula, data, subset, na.action, lambda = 0, model = FALSE,
          x = FALSE, y = FALSE, contrasts = NULL, ...)
```

Arguments

- `formula`: a formula expression as for regression models, of the form `response ~ predictors`. See the documentation of `formula` for other details. `offset` terms are allowed.
- `data`: an optional data frame in which to interpret the variables occurring in `formula`.
- `subset`: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
- `na.action`: a function to filter missing data.
- `lambda`: A scalar or vector of ridge constants.
- `model`: should the model frame be returned? Not implemented.
- `x`: should the design matrix be returned? Not implemented.
- `y`: should the response be returned? Not implemented.
- `contrasts`: a list of contrasts to be used for some or all of factor terms in the formula. See the `contrasts.arg` of `model.matrix.default`.
- `...`: additional arguments to `lm.fit`.

Details

If an intercept is present in the model, its coefficient is not penalized. (If you want to penalize an intercept, put in your own constant term and remove the intercept.)

Value

A list with components

- `coef`: matrix of coefficients, one row for each value of `lambda`. Note that these are not on the original scale and are for use by the `coef` method.
- `scales`: scalings used on the X matrix.
- `Inter`: was intercept included?
- `lambda`: vector of lambda values
- `ym`: mean of `y`
- `xm`: column means of `x` matrix
- `GCV`: vector of GCV values
- `kHKB`: HKB estimate of the ridge constant.
- `kLW`: L-W estimate of the ridge constant.

loglm

Fit Log-Linear Models by Iterative Proportional Scaling

Description

This function provides a front-end to the standard function, loglm, to allow log-linear models to be specified and fitted in a manner similar to that of other fitting functions, such as glm.

Usage

loglm(formula, data, subset, na.action, ...)

Arguments

formula A linear model formula specifying the log-linear model.
If the left-hand side is empty, the data argument is required and must be a (complete) array of frequencies. In this case the variables on the right-hand side may be the names of the dimnames attribute of the frequency array, or may be the positive integers: 1, 2, 3, ... used as alternative names for the 1st, 2nd, 3rd, ...dimension (classifying factor). If the left-hand side is not empty it specifies a vector of frequencies. In this case the data argument, if present, must be a data frame from which the left-hand side vector and the classifying factors on the right-hand side are (preferentially) obtained. The usual abbreviation of a . to stand for ‘all other variables in the data frame’ is allowed. Any non-factors on the right-hand side of the formula are coerced to factor.

data Numeric array or data frame. In the first case it specifies the array of frequencies; in the second it provides the data frame from which the variables occurring in the formula are preferentially obtained in the usual way. This argument may be the result of a call to xtabs.

subset Specifies a subset of the rows in the data frame to be used. The default is to take all rows.

na.action Specifies a method for handling missing observations. The default is to fail if missing values are present.

... May supply other arguments to the function loglm.
Details

If the left-hand side of the formula is empty the `data` argument supplies the frequency array and the right-hand side of the formula is used to construct the list of fixed faces as required by `loglin`. Structural zeros may be specified by giving a `start` argument with those entries set to zero, as described in the help information for `loglin`.

If the left-hand side is not empty, all variables on the right-hand side are regarded as classifying factors and an array of frequencies is constructed. If some cells in the complete array are not specified they are treated as structural zeros. The right-hand side of the formula is again used to construct the list of faces on which the observed and fitted totals must agree, as required by `loglin`. Hence terms such as `a:b`, `a*b` and `a/b` are all equivalent.

Value

An object of class "loglm" conveying the results of the fitted log-linear model. Methods exist for the generic functions `print`, `summary`, `deviance`, `fitted`, `coef`, `resid`, `anova` and `update`, which perform the expected tasks. Only log-likelihood ratio tests are allowed using `anova`.

The deviance is simply an alternative name for the log-likelihood ratio statistic for testing the current model within a saturated model, in accordance with standard usage in generalized linear models.

Warning

If structural zeros are present, the calculation of degrees of freedom may not be correct. `loglin` itself takes no action to allow for structural zeros. `loglm` deducts one degree of freedom for each structural zero, but cannot make allowance for gains in error degrees of freedom due to loss of dimension in the model space. (This would require checking the rank of the model matrix, but since iterative proportional scaling methods are developed largely to avoid constructing the model matrix explicitly, the computation is at least difficult.)

When structural zeros (or zero fitted values) are present the estimated coefficients will not be available due to infinite estimates. The deviances will normally continue to be correct, though.

# in the MASS package.

# Case 1: frequencies specified as an array.
sapply(minn38, function(x) length(levels(x)))
## hs phs fol sex f
## 3 4 7 2 0
##minn38a <- array(0, c(3,4,7,2), lapply(minn38[, -5], levels))
##minn38a[ data.matrix(minn38[, -5]) ] <- minn38$f

## or more simply
minn38a <- xtabs(f ~ ., minn38)
```
logtrans

Description

Find and optionally plot the marginal (profile) likelihood for alpha for a transformation model of the form \( \log(y + \alpha) \sim x_1 + x_2 + \ldots \).

Usage

logtrans(object, ...)

## Default S3 method:
logtrans(object, ..., alpha = seq(0.5, 6, by = 0.25) - min(y), plotit = TRUE, interp =, xlab = "alpha", ylab = "log Likelihood")

## S3 method for class 'formula'
logtrans(object, data, ...)

## S3 method for class 'lm'
logtrans(object, ...)

Arguments

object Fitted linear model object, or formula defining the untransformed model that is \( y \sim x_1 + x_2 + \ldots \). The function is generic.

... If object is a formula, this argument may specify a data frame as for \texttt{lm}. 
alpha  Set of values for the transformation parameter, alpha.
plotit Should plotting be done?
interp Should the marginal log-likelihood be interpolated with a spline approximation?
(Default is TRUE if plotting is to be done and the number of real points is less than 100.)
xlab as for plot.
ylab as for plot.
data optional data argument for lm fit.

Value
List with components x (for alpha) and y (for the marginal log-likelihood values).

Side Effects
A plot of the marginal log-likelihood is produced, if requested, together with an approximate mle and 95\% confidence interval.

References

See Also
boxcox

Examples
logtrans(Days ~ Age*Sex*Eth*Lrn, data = quine,
alpha = seq(0.75, 6.5, len=20))

Description
Fit a regression to the good points in the dataset, thereby achieving a regression estimator with a high breakdown point. lmsreg and ltsreg are compatibility wrappers.

Usage
lqs(x, ...)

## S3 method for class 'formula'
lqs(formula, data, ..., 
method = c("lts", "lqs", "lm", "S", "model.frame"),
subset, na.action, model = TRUE,
x.ret = FALSE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
lqs(x, y, intercept = TRUE, method = c("lts", "lqs", "lm", "S"),
quantile, control = lqs.control(...), k0 = 1.548, seed, ...)
lmsreg(...)
ltsreg(...)

Arguments

- **formula**: a formula of the form $y \sim x_1 + x_2 + \ldots$
- **data**: data frame from which variables specified in `formula` are preferentially to be taken.
- **subset**: an index vector specifying the cases to be used in fitting. (NOTE: If given, this argument must be named exactly.)
- **na.action**: function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. Alternatives include `na.omit` and `na.exclude`, which lead to omission of cases with missing values on any required variable. (NOTE: If given, this argument must be named exactly.)
- **model, x.ret, y.ret**: logical. If TRUE the model frame, the model matrix and the response are returned, respectively.
- **contrasts**: an optional list. See the `contrasts.arg` of `model.matrix.default`.
- **x**: a matrix or data frame containing the explanatory variables.
- **y**: the response: a vector of length the number of rows of `x`.
- **intercept**: should the model include an intercept?
- **method**: the method to be used. `model.frame` returns the model frame: for the others see the Details section. Using `lmsreg` or `ltsreg` forces "lms" and "lts" respectively.
- **quantile**: the quantile to be used: see Details. This is over-ridden if `method = "lms"`.
- **control**: additional control items: see Details.
- **k0**: the cutoff/tuning constant used for $\chi()$ and $\psi()$ functions when `method = "S"`, currently corresponding to Tukey's 'biweight'.
- **seed**: the seed to be used for random sampling: see `.Random.seed`. The current value of `.Random.seed` will be preserved if it is set.
- **...**: arguments to be passed to `lqs.default` or `lqs.control`, see `control` above and Details.

Details

Suppose there are $n$ data points and $p$ regressors, including any intercept.

The first three methods minimize some function of the sorted squared residuals. For methods "lqs" and "lms" is the quantile squared residual, and for "lts" it is the sum of the quantile smallest squared residuals. "lqs" and "lms" differ in the defaults for `quantile`, which are `floor((n+p+1)/2)` and `floor((n+1)/2)` respectively. For "lts" the default is `floor(n/2) + floor((p+1)/2)`.

The "S" estimation method solves for the scale $s$ such that the average of a function chi of the residuals divided by $s$ is equal to a given constant.

The `control` argument is a list with components

- `psamp`: the size of each sample. Defaults to $p$. 
**nsamp**: the number of samples or "best" (the default) or "exact" or "sample". If "sample" the number chosen is $\min(5p, \ 3000)$, taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples; if "exact" exhaustive enumeration will be attempted however many samples are needed.

**adjust**: should the intercept be optimized for each sample? Defaults to TRUE.

**Value**

An object of class "lqs". This is a list with components

- **crit**: the value of the criterion for the best solution found, in the case of method == "S" before IWLS refinement.
- **sing**: character. A message about the number of samples which resulted in singular fits.
- **coefficients**: of the fitted linear model
- **bestone**: the indices of those points fitted by the best sample found (prior to adjustment of the intercept, if requested).
- **fitted.values**: the fitted values.
- **residuals**: the residuals.
- **scale**: estimate(s) of the scale of the error. The first is based on the fit criterion. The second (not present for method == "S") is based on the variance of those residuals whose absolute value is less than 2.5 times the initial estimate.

**Note**

There seems no reason other than historical to use the lms and lqs options. LMS estimation is of low efficiency (converging at rate $n^{-1/3}$) whereas LTS has the same asymptotic efficiency as an M estimator with trimming at the quartiles (Marazzi, 1993, p.201). LQS and LTS have the same maximal breakdown value of $(\text{floor}((n-p)/2) + 1)/n$ attained if $\text{floor}((n+p)/2) \leq \text{quantile} \leq \text{floor}((n+p+1)/2)$. The only drawback mentioned of LTS is greater computation, as a sort was thought to be required (Marazzi, 1993, p.201) but this is not true as a partial sort can be used (and is used in this implementation).

Adjusting the intercept for each trial fit does need the residuals to be sorted, and may be significant extra computation if $n$ is large and $p$ small.

Opinions differ over the choice of nsamp. Rousseeuw and Hubert (1997) only consider $p$; Marazzi (1993) recommends $p+1$ and suggests that more samples are better than adjustment for a given computational limit.

The computations are exact for a model with just an intercept and adjustment, and for LQS for a model with an intercept plus one regressor and exhaustive search with adjustment. For all other cases the minimization is only known to be approximate.

mca

Multiple Correspondence Analysis

Description

Computes a multiple correspondence analysis of a set of factors.

Usage

mca(df, nf = 2, abbrev = FALSE)

Arguments

df A data frame containing only factors
nf The number of dimensions for the MCA. Rarely 3 might be useful.
abbrev Should the vertex names be abbreviated? By default these are of the form ‘factor.level’ but if abbrev = TRUE they are just ‘level’ which will suffice if the factors have distinct levels.

Value

An object of class "mca", with components

rs The coordinates of the rows, in nf dimensions.
cs The coordinates of the column vertices, one for each level of each factor.
fs Weights for each row, used to interpolate additional factors in predict.mca.
p The number of factors
d The singular values for the nf dimensions.
call The matched call.

Melanoma  \hspace{1cm} Survival from Malignant Melanoma

**Description**

The *Melanoma* data frame has data on 205 patients in Denmark with malignant melanoma.

**Usage**

Melanoma

**Format**

This data frame contains the following columns:

- time: survival time in days, possibly censored.
- status: 1 died from melanoma, 2 alive, 3 dead from other causes.
- sex: 1 = male, 0 = female.
- age: age in years.
- year: year of operation.
- thickness: tumour thickness in mm.
- ulcer: 1 = presence, 0 = absence.
Description

Proportions of female children at various ages during adolescence who have reached menarche.

Usage

menarche

Format

This data frame contains the following columns:

- **Age**: Average age of the group. (The groups are reasonably age homogeneous.)
- **Total**: Total number of children in the group.
- **Menarche**: Number who have reached menarche.

Source

Michelson’s Speed of Light Data

Description

Measurements of the speed of light in air, made between 5th June and 2nd July, 1879. The data consists of five experiments, each consisting of 20 consecutive runs. The response is the speed of light in km/s, less 299000. The currently accepted value, on this scale of measurement, is 734.5.

Usage

michelson

Format

The data frame contains the following components:

- Expt: The experiment number, from 1 to 5.
- Run: The run number within each experiment.
- Speed: Speed-of-light measurement.

Effect of Calcium Chloride on Muscle Contraction in Rat Hearts

Description

The purpose of this experiment was to assess the influence of calcium in solution on the contraction of heart muscle in rats. The left auricle of 21 rat hearts was isolated and on several occasions a constant-length strip of tissue was electrically stimulated and dipped into various concentrations of calcium chloride solution, after which the shortening of the strip was accurately measured as the response.

Usage

musc

Format

This data frame contains the following columns:

- Strip   which heart muscle strip was used?
- Conc    concentration of calcium chloride solution, in multiples of 2.2 mM.
- Length  the change in length (shortening) of the strip, (allegedly) in mm.

Source

References

Examples

```r
A <- model.matrix(~ Strip - 1, data=musc)
rats.nls1 <- nls(log(Length) ~ cbind(A, rho*Conc),
               data = musc, start = c(rho=0.1), algorithm="plinear")
(B <- coef(rats.nls1))

st <- list(alpha = B[2:22], beta = B[23], rho = B[1])
(rats.nls2 <- nls(log(Length) ~ alpha[Strip] + beta*rho*Conc,
               data = musc, start = st))

Muscle <- with(musc, {.
  Muscle <- expand.grid(Conc = sort(unique(Conc)), Strip = levels(Strip))
  Muscle$Yhat <- predict(rats.nls2, Muscle)
  Muscle <- cbind(Muscle, logLength = rep(as.numeric(NA), 126))
})
```
mvrnorm

Simulate from a Multivariate Normal Distribution

Description

Produces one or more samples from the specified multivariate normal distribution.

Usage

mvrnorm(n = 1, mu, Sigma, tol = 1e-6, empirical = FALSE, EISPACK = FALSE)

Arguments

n the number of samples required.
mu a vector giving the means of the variables.
Sigma a positive-definite symmetric matrix specifying the covariance matrix of the variables.
tol tolerance (relative to largest variance) for numerical lack of positive-definiteness in Sigma.
empirical logical. If true, mu and Sigma specify the empirical not population mean and covariance matrix.
EISPACK logical. Set to true to reproduce results from MASS versions prior to 3.1-21.

Details

The matrix decomposition is done via eigen; although a Choleski decomposition might be faster, the eigendecomposition is stabler.

Value

If n = 1 a vector of the same length as mu, otherwise an n by length(mu) matrix with one sample in each row.

Side Effects

Causes creation of the dataset .Random.seed if it does not already exist, otherwise its value is updated.

IQ <- IQ ~ IQave
)
cen <- c("IQ", "IQave", "SES")
 nl1[cen] <- scale(nl1[cen], center = TRUE, scale = FALSE)

nl.lme <- nlme::lme(lang ~ IQ*COMB + IQave + SES,
                   random = ~ IQ | class, data = nl1)
summary(nl.lme)
```

npk

Classical N, P, K Factorial Experiment

Description

A classical N, P, K (nitrogen, phosphate, potassium) factorial experiment on the growth of peas conducted on 6 blocks. Each half of a fractional factorial design confounding the NPK interaction was used on 3 of the plots.

Usage

npk

Format

The npk data frame has 24 rows and 5 columns:

- block which block (label 1 to 6).
- N indicator (0/1) for the application of nitrogen.
- P indicator (0/1) for the application of phosphate.
- K indicator (0/1) for the application of potassium.
- yield Yield of peas, in pounds/plot (the plots were (1/70) acre).

Note

This dataset is also contained in R 3.0.2 and later.

model.tables(oats.aov2, type = "means", se = TRUE)
```
Tests of Auditory Perception in Children with OME

Description

Experiments were performed on children on their ability to differentiate a signal in broad-band noise. The noise was played from a pair of speakers and a signal was added to just one channel; the subject had to turn his/her head to the channel with the added signal. The signal was either coherent (the amplitude of the noise was increased for a period) or incoherent (independent noise was added for the same period to form the same increase in power).

The threshold used in the original analysis was the stimulus loudness needs to get 75% correct responses. Some of the children had suffered from otitis media with effusion (OME).

Usage

OME

Format

The OME data frame has 1129 rows and 7 columns:

ID Subject ID (1 to 99, with some IDs missing). A few subjects were measured at different ages.

OME "low" or "high" or "N/A" (at ages other than 30 and 60 months).

Age Age of the subject (months).

Loud Loudness of stimulus, in decibels.

Noise Whether the signal in the stimulus was "coherent" or "incoherent".

Correct Number of correct responses from Trials trials.

Trials Number of trials performed.

Background

The experiment was to study otitis media with effusion (OME), a very common childhood condition where the middle ear space, which is normally air-filled, becomes congested by a fluid. There is a concomitant fluctuating, conductive hearing loss which can result in various language, cognitive and social deficits. The term ‘binaural hearing’ is used to describe the listening conditions in which the brain is processing information from both ears at the same time. The brain computes differences in the intensity and/or timing of signals arriving at each ear which contributes to sound localisation and also to our ability to hear in background noise.

Some years ago, it was found that children of 7–8 years with a history of significant OME had significantly worse binaural hearing than children without such a history, despite having equivalent sensitivity. The question remained as to whether it was the timing, the duration, or the degree of severity of the otitis media episodes during critical periods, which affected later binaural hearing. In an attempt to begin to answer this question, 95 children were monitored for the presence of effusion every month since birth. On the basis of OME experience in their first two years, the test population was split into one group of high OME prevalence and one of low prevalence.

**painters**

---

**The Painter’s Data of de Piles**

**Description**

The subjective assessment, on a 0 to 20 integer scale, of 54 classical painters. The painters were assessed on four characteristics: composition, drawing, colour and expression. The data is due to the Eighteenth century art critic, de Piles.

**Usage**

`painters`
pairs.lda

Format

The row names of the data frame are the painters. The components are:

Composition Composition score.
Drawing Drawing score.
Colour Colour score.
Expression Expression score.

School The school to which a painter belongs, as indicated by a factor level code as follows: "A": Renaissance; "B": Mannerist; "C": Seicento; "D": Venetian; "E": Lombard; "F": Sixteenth Century; "G": Seventeenth Century; "H": French.

pairs.lda

Produce Pairwise Scatterplots from an 'lda' Fit

Description

Pairwise scatterplot of the data on the linear discriminants.

Usage

## S3 method for class 'lda'
pairs(x, labels = colnames(x), panel = panel.lda,
      dimen, abbrev = FALSE, ..., cex=0.7, type = c("std", "trellis"))

Arguments

x Object of class "lda".
labels vector of character strings for labelling the variables.
panel panel function to plot the data in each panel.
dimen The number of linear discriminants to be used for the plot; if this exceeds the number determined by x the smaller value is used.
abbrev whether the group labels are abbreviated on the plots. If abbrev > 0 this gives minlength in the call to abbreviate.
... additional arguments for pairs.default.
cex graphics parameter cex for labels on plots.
type type of plot. The default is in the style of pairs.default; the style "trellis" uses the Trellis function splom.
Details

This function is a method for the generic function `pairs()` for class "lda". It can be invoked by calling `pairs(x)` for an object `x` of the appropriate class, or directly by calling `pairs.lda(x)` regardless of the class of the object.

`pairs`

`parcoord` Parallel Coordinates Plot

Description

Parallel coordinates plot

Usage

```r
parcoord(x, col = 1, lty = 1, var.label = FALSE, ...)
```

Arguments

- `x` a matrix or data frame who columns represent variables. Missing values are allowed.
- `col` A vector of colours, recycled as necessary for each observation.
- `lty` A vector of line types, recycled as necessary for each observation.
- `var.label` If TRUE, each variable’s axis is labelled with maximum and minimum values.
- `...` Further graphics parameters which are passed to `matplot`.

Side Effects

a parallel coordinates plots is drawn.

Author(s)

B. D. Ripley. Enhancements based on ideas and code by Fabian Scheipl.

References

Examples

```r
parcoord(state.x77[, c(7, 4, 6, 2, 5, 3)])
ir <- rbind(iris3[,1], iris3[,2], iris3[,3])
parcoord(log(ir)[, c(3, 4, 2, 1)], col = 1 + (0 : 149)%%50)
```
Description
The yield of a petroleum refining process with four covariates. The crude oil appears to come from
only 10 distinct samples.
These data were originally used by Prater (1956) to build an estimation equation for the yield of the
refining process of crude oil to gasoline.

Usage
petrol

Format
The variables are as follows

No crude oil sample identification label. (Factor.)
SG specific gravity, degrees API. (Constant within sample.)
VP vapour pressure in pounds per square inch. (Constant within sample.)
V10 volatility of crude; ASTM 10% point. (Constant within sample.)
EP desired volatility of gasoline. (The end point. Varies within sample.)
Y yield as a percentage of crude.

Source
This dataset is also given in D. J. Hand, F. Daly, K. McConway, D. Lunn and E. Ostrowski (eds)

Examples
library(nlme)
Petrol <- petrol
Petrol[, 2:5] <- scale(as.matrix(Petrol[, 2:5]), scale = FALSE)
pet3.1me <- lme(Y ~ SG + VP + V10 + EP,
random = ~ 1 | No, data = Petrol)
pet3.1me <- update(pet3.1me, method = "ML")
pet4.1me <- update(pet3.1me, fixed = Y ~ V10 + EP)
aova(pet4.1me, pet3.1me)
Description

A population of women who were at least 21 years old, of Pima Indian heritage and living near Phoenix, Arizona, was tested for diabetes according to World Health Organization criteria. The data were collected by the US National Institute of Diabetes and Digestive and Kidney Diseases. We used the 532 complete records after dropping the (mainly missing) data on serum insulin.

Usage

Pima.tr
Pima.tr2
Pima.te

Format

These data frames contains the following columns:

- npreg  number of pregnancies.
- glu  plasma glucose concentration in an oral glucose tolerance test.
- bp  diastolic blood pressure (mm Hg).
- skin  triceps skin fold thickness (mm).
- bmi  body mass index (weight in kg/(height in m)$^2$).
- ped  diabetes pedigree function.
- age  age in years.
- type  Yes or No, for diabetic according to WHO criteria.

Details

The training set Pima.tr contains a randomly selected set of 200 subjects, and Pima.te contains the remaining 332 subjects. Pima.tr2 contains Pima.tr plus 100 subjects with missing values in the explanatory variables.

Source

plot.lda

Description

Plots a set of data on one, two or more linear discriminants.

Usage

```r
## S3 method for class 'lda'
plot(x, panel = panel.lda, ..., cex = 0.7, dimen,
     abbrev = FALSE, xlab = "LD1", ylab = "LD2")
```

Arguments

- `x`: An object of class "lda".
- `panel`: the panel function used to plot the data.
- `...`: additional arguments to `pairs`, `ldahist` or `eqscplot`.
- `cex`: graphics parameter `cex` for labels on plots.
- `dimen`: The number of linear discriminants to be used for the plot; if this exceeds the number determined by `x` the smaller value is used.
- `abbrev`: whether the group labels are abbreviated on the plots. If `abbrev > 0` this gives `minlength` in the call to `abbreviate`.
- `xlab`: label for the x axis
- `ylab`: label for the y axis

Details

This function is a method for the generic function `plot()` for class "lda". It can be invoked by calling `plot(x)` for an object `x` of the appropriate class, or directly by calling `plot.lda(x)` regardless of the class of the object.

The behaviour is determined by the value of `dimen`. For `dimen > 2`, a `pairs` plot is used. For `dimen = 2`, an equiscaled scatter plot is drawn. For `dimen = 1`, a set of histograms or density plots are drawn. Use argument `type` to match "histogram" or "density" or "both".

plot.mca

Plot Method for Objects of Class 'mca'

Description
Plot a multiple correspondence analysis.

Usage

```r
## S3 method for class 'mca'
plot(x, rows = TRUE, col, cex = par("cex"), ...)
```

Arguments

- `x`: An object of class "mca".
- `rows`: Should the coordinates for the rows be plotted, or just the vertices for the levels?
- `col, cex`: The colours and cex to be used for the row points and level vertices respectively.
- `...`: Additional parameters to plot.

References

`mca`, `predict.mca`

Examples

```r
plot(mca(farms, abbrev = TRUE))
```

plot.profile

Plotting Functions for 'profile' Objects

Description
`plot` and `pairs` methods for objects of class "profile".

Usage

```r
## S3 method for class 'profile'
plot(x, ...)
## S3 method for class 'profile'
pairs(x, colours = 2:3, ...)
```

Arguments

- `x`: an object inheriting from class "profile".
- `colours`: Colours to be used for the mean curves conditional on x and y respectively.
- `...`: arguments passed to or from other methods.
Details

This is the main plot method for objects created by `profile.glm`. It can also be called on objects created by `profile.nls`, but they have a specific method, `plot.profile.nls`.

The `pairs` method shows, for each pair of parameters $x$ and $y$, two curves intersecting at the maximum likelihood estimate, which give the loci of the points at which the tangents to the contours of the bivariate profile likelihood become vertical and horizontal, respectively. In the case of an exactly bivariate normal profile likelihood, these two curves would be straight lines giving the conditional means of $y|x$ and $x|y$, and the contours would be exactly elliptical.

Author(s)

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

`profile.glm`, `profile.nls`.

Examples

```r
## see ?profile.glm for an example using glm fits.

## a version of example(profile.nls) from R >= 2.8.0
fml <- nls(demand ~ SSasympOrig(Time, A, lrc), data = BOD)
pr1 <- profile(fml, alpha = 0.1)
MASS::plot.profile(pr1)
pairs(pr1) # a little odd since the parameters are highly correlated

## an example from ?nls
x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10
nlmod <- nls(y ~ Const + A * exp(B * x), start=list(Const=100, A=10, B=1))
pairs(profile(nlmod))
```

---

**polr**

**Ordered Logistic or Probit Regression**

Description

Fits a logistic or probit regression model to an ordered factor response. The default logistic case is *proportional odds logistic regression*, after which the function is named.

Usage

```r
polr(formula, data, weights, start, ..., subset, na.action,
    contrasts = NULL, Hess = FALSE, model = TRUE,
    method = c("logistic", "probit", "loglog", "cloglog", "cauchit"))
```
Arguments

- **formula**: a formula expression as for regression models, of the form `response ~ predictors`. The response should be a factor (preferably an ordered factor), which will be interpreted as an ordinal response, with levels ordered as in the factor. The model must have an intercept; attempts to remove one will lead to a warning and be ignored. An offset may be used. See the documentation of `formula` for other details.

- **data**: an optional data frame in which to interpret the variables occurring in `formula`.

- **weights**: optional case weights in fitting. Default to 1.

- **start**: initial values for the parameters. This is in the format `c(coefficients, zeta)`: see the Values section.

- **...**: additional arguments to be passed to `optim`, most often a control argument.

- **subset**: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.

- **na.action**: a function to filter missing data.

- **contrasts**: a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.

- **Hess**: logical for whether the Hessian (the observed information matrix) should be returned. Use this if you intend to call `summary` or `vcov` on the fit.

- **model**: logical for whether the model matrix should be returned.

- **method**: logistic or probit or (complementary) log-log or cauchit (corresponding to a Cauchy latent variable).

Details

This model is what Agresti (2002) calls a cumulative link model. The basic interpretation is as a coarsened version of a latent variable $Y_i$ which has a logistic or normal or extreme-value or Cauchy distribution with scale parameter one and a linear model for the mean. The ordered factor which is observed is which bin $Y_i$ falls into with breakpoints

$$
\zeta_0 = -\infty < \zeta_1 < \cdots < \zeta_K = \infty
$$

This leads to the model

$$
\text{logit} P(Y \leq k | x) = \zeta_k - \eta
$$

with logit replaced by probit for a normal latent variable, and $\eta$ being the linear predictor, a linear function of the explanatory variables (with no intercept). Note that it is quite common for other software to use the opposite sign for $\eta$ (and hence the coefficients beta).

In the logistic case, the left-hand side of the last display is the log odds of category $k$ or less, and since these are log odds which differ only by a constant for different $k$, the odds are proportional. Hence the term proportional odds logistic regression.

The log-log and complementary log-log links are the increasing functions $F^{-1}(p) = -\log(-\log(p))$ and $F^{-1}(p) = \log(-\log(1 - p))$: some call the first the ‘negative log-log’ link. These correspond to a latent variable with the extreme-value distribution for the maximum and minimum respectively.

A proportional hazards model for grouped survival times can be obtained by using the complementary log-log link with grouping ordered by increasing times.

`predict`, `summary`, `vcov`, `anova`, `model.frame` and an extractAIC method for use with `stepAIC` (and `step`). There are also `profile` and `confint` methods.
Value

A object of class "polr". This has components

- `coefficients` the coefficients of the linear predictor, which has no intercept.
- `zeta` the intercepts for the class boundaries.
- `deviance` the residual deviance.
- `fitted.values` a matrix, with a column for each level of the response.
- `lev` the names of the response levels.
- `terms` the terms structure describing the model.
- `df.residual` the number of residual degrees of freedoms, calculated using the weights.
- `edf` the (effective) number of degrees of freedom used by the model
- `nobs` the (effective) number of observations, calculated using the weights. (nobs is for use by `stepAIC`.
- `call` the matched call.
- `method` the matched method used.
- `convergence` the convergence code returned by `optim`.
- `niter` the number of function and gradient evaluations used by `optim`.
- `lp` the linear predictor (including any offset).
- `Hessian` (if Hess is true). Note that this is a numerical approximation derived from the optimization proces.
- `model` (if model is true).

Note

The vcov method uses the approximate Hessian: for reliable results the model matrix should be sensibly scaled with all columns having range the order of one.

Prior to version 7.3-32, method = "clloglog" confusingly gave the log-log link, implicitly assuming the first response level was the ‘best’.

Examples

```r
options(contrasts = c("contr.treatment", "contr.poly"))
house.plr <- polr(Sat ~ Infl + Type + Cont, weights = Freq, data = housing)
house.plr
summary(house.plr, digits = 3)
## slightly worse fit from
summary(update(house.plr, method = "probit", Hess = TRUE), digits = 3)
## although it is not really appropriate, can fit
summary(update(house.plr, method = "loglog", Hess = TRUE), digits = 3)
```
predict.glmmPQL

Predict Method for glmmPQL Fits

Description

Obtains predictions from a fitted generalized linear model with random effects.

Usage

## S3 method for class 'glmmPQL'
predict(object, newdata = NULL, type = c("link", "response"),
      level, na.action = na.pass, ...)

Arguments

object a fitted object of class inheriting from "glmmPQL".
newdata optionally, a data frame in which to look for variables with which to predict.
type the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities.
level an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.
na.action function determining what should be done with missing values in newdata. The default is to predict NA.
... further arguments passed to or from other methods.

Value

If level is a single integer, a vector otherwise a data frame.

See Also

glmmPQL, predict.lme.
Examples

```r
fit <- glmPQL(y ~ trt + I(week > 2), random = ~1 | ID,
             family = binomial, data = bacteria)
predict(fit, bacteria, level = 0, type="response")
predict(fit, bacteria, level = 1, type="response")
```

Description

Classify multivariate observations in conjunction with `lda`, and also project data onto the linear discriminants.

Usage

```r
## S3 method for class 'lda'
predict(object, newdata, prior = object$prior, dimen,
         method = c("plug-in", "predictive", "debiased"), ...)
```

Arguments

- `object`  
  object of class "lda"

- `newdata`  
  data frame of cases to be classified or, if `object` has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If `newdata` is missing, an attempt will be made to retrieve the data used to fit the `lda` object.

- `prior`  
  The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to `lda`.

- `dimen`  
  the dimension of the space to be used. If this is less than \( \min(p, ng-1) \), only the first `dimen` discriminant components are used (except for `method="predictive"`), and only those dimensions are returned in `x`.

- `method`  
  This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior.

- `...`  
  arguments based from or to other methods

Details

This function is a method for the generic function `predict()` for class "lda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

This version centres the linear discriminants so that the weighted mean (weighted by `prior`) of the group centroids is at the origin.
Value

A list with components

- class: The MAP classification (a factor)
- posterior: posterior probabilities for the classes
- x: the scores of test cases on up to `dimen` discriminant variables

References

`lda, qda, predict.qda`

Examples

```r
tr <- sample(1:50, 25)
train <- rbind(iris3[tr,,1], iris3[tr,,2], iris3[tr,,3])
test <- rbind(iris3[-tr,,1], iris3[-tr,,2], iris3[-tr,,3])
c1 <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
z <- lda(train, cl)
predict(z, test)$class
```

Description

Predict from an resistant regression fitted by `lqs`.

Usage

```r
## S3 method for class 'lqs'
predict(object, newdata, na.action = na.pass, ...)
```

Arguments

- `object`: object inheriting from class "lqs"
- `newdata`: matrix or data frame of cases to be predicted or, if `object` has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If `newdata` is missing, an attempt will be made to retrieve the data used to fit the `lqs` object.
- `na.action`: function determining what should be done with missing values in `newdata`. The default is to predict `NA`.
- `...`: arguments to be passed from or to other methods.
This function is a method for the generic function `predict()` for class `lm`. It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lm(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear fit cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

A vector of predictions.

B.D. Ripley

`lm`

**Examples**

```r
set.seed(123)
fmm = lm(stack.loss ~ ., data = stackloss, method = "S", nsamp = "exact")
predict(fm, stackloss)
```

**Description**

Used to compute coordinates for additional rows or additional factors in a multiple correspondence analysis.

**Usage**

```r
## S3 method for class 'mca'
predict(object, newdata, type = c("row", "factor"), ...)
```

**Arguments**

- `object`: An object of class `"mca"`, usually the result of a call to `mca`.
- `newdata`: A data frame containing *either* additional rows of the factors used to fit object *or* additional factors for the cases used in the original fit.
- `type`: Are predictions required for further rows or for new factors?
- `...`: Additional arguments from `predict`: unused.

**Value**

If `type = "row"`, the coordinates for the additional rows.

If `type = "factor"`, the coordinates of the column vertices for the levels of the new factors.

mca, plot.mca

predict.qda

Classify from Quadratic Discriminant Analysis

Description

Classify multivariate observations in conjunction with qda

Usage

```r
## S3 method for class 'qda'
predict(object, newdata, prior = object$prior,
       method = c("plug-in", "predictive", "debiased", "loocv"), ...)
```

Arguments

- **object**: object of class "qda"
- **newdata**: data frame of cases to be classified, or, if `object` has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If `newdata` is missing, an attempt will be made to retrieve the data used to fit the `qda` object.
- **prior**: The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to `qda`.
- **method**: This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior. With "loocv" the leave-one-out cross-validation fits to the original dataset are computed and returned.
- **...**: arguments based from or to other methods

Details

This function is a method for the generic function `predict()` for class "qda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.qda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the quadratic discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.
Value

a list with components

- **class**: The MAP classification (a factor)
- **posterior**: posterior probabilities for the classes

cl <- factor(c(rep("s", 25), rep("c", 25), rep("v", 25)))

tq <- qda(train, cl)
predict(tq, test)$class
```

profile.glm  

Method for Profiling glm Objects

Description

Investigates the profile log-likelihood function for a fitted model of class "glm".

Usage

```r
## S3 method for class 'glm'
profile(fitted, which = 1:p, alpha = 0.01, maxsteps = 10,
       del = zmax/5, trace = FALSE, ...)
```

Arguments

- **fitted**: the original fitted model object.
- **which**: the original model parameters which should be profiled. This can be a numeric or character vector. By default, all parameters are profiled.
- **alpha**: highest significance level allowed for the profile t-statistics.
- **maxsteps**: maximum number of points to be used for profiling each parameter.
- **del**: suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.
- **trace**: logical: should the progress of profiling be reported?
- **...**: further arguments passed to or from other methods.
Details

The profile t-statistic is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

Value

A list of classes "profile.glm" and "profile" with an element for each parameter being profiled. The elements are data-frames with two variables

- par.vals: a matrix of parameter values for each fitted model.
- tau: the profile t-statistics.

Author(s)

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

Examples

```r
options(contrasts = c("contr.treatment", "contr.poly"))
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg <- glm(SF ~ sex*ldose, family = binomial)
pr1 <- profile(budworm.lg)
plot(pr1)
pairs(pr1)
```

qda

Quadratic Discriminant Analysis

Description

Quadratic discriminant analysis.

Usage

```r
qda(x, ...)
```

## S3 method for class 'formula'
qda(formula, data, ..., subset, na.action)

## Default S3 method:
qda(x, grouping, prior = proportions,
method, CV = FALSE, nu, ...)

## S3 method for class 'data.frame'
qda(x, ...)
### S3 method for class 'matrix'

```r
qda(x, grouping, ..., subset, na.action)
```

**Arguments**

- `formula` A formula of the form `groups ~ x1 + x2 + ...` That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.
- `data` Data frame from which variables specified in `formula` are preferentially to be taken.
- `x` (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.
- `grouping` (required if no formula principal argument is given.) a factor specifying the class for each observation.
- `prior` the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If specified, the probabilities should be specified in the order of the factor levels.
- `subset` An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
- `na.action` A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is `na.omit`, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
- `method` "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use `cov.mve`, or "t" for robust estimates based on a t distribution.
- `CV` If true, returns results (classes and posterior probabilities) for leave-out-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.
- `nu` degrees of freedom for `method = "t"`.
- `...` arguments passed to or from other methods.

**Details**

Uses a QR decomposition which will give an error message if the within-group variance is singular for any group.

**Value**

An object of class "qda" containing the following components:

- `prior` the prior probabilities used.
- `means` the group means.
- `scaling` for each group i, `scaling[,]i` is an array which transforms observations so that within-groups covariance matrix is spherical.
- `ldet` a vector of half log determinants of the dispersion matrix.
- `lev` the levels of the grouping factor.
- `terms` (if formula is a formula) an object of mode expression and class term summarizing the formula.
call the (matched) function call.

unless CV=TRUE, when the return value is a list with components:

class The MAP classification (a factor)
posterior posterior probabilities for the classes

cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
z <- qda(train, cl)
predict(z,test)$class
```

---

### quine

**Absenteeism from School in Rural New South Wales**

**Description**

The quine data frame has 146 rows and 5 columns. Children from Walgett, New South Wales, Australia, were classified by Culture, Age, Sex and Learner status and the number of days absent from school in a particular school year was recorded.

**Usage**

quine

**Format**

This data frame contains the following columns:

- Eth ethnic background: Aboriginal or Not, ("A" or "N").
- Sex: sex: factor with levels ("F" or "M").
- Age age group: Primary ("F0"), or forms "F1", "F2" or "F3".
- Lrn learner status: factor with levels Average or Slow learner, ("AL" or "SL").
- Days days absent from school in the year.

**Source**

Description

Five rabbits were studied on two occasions, after treatment with saline (control) and after treatment with the 5−HT₃ antagonist MDL 72222. After each treatment ascending doses of phenylbiguanide were injected intravenously at 10 minute intervals and the responses of mean blood pressure measured. The goal was to test whether the cardiogenic chemoreflex elicited by phenylbiguanide depends on the activation of 5−HT₃ receptors.

Usage

Rabbit

Format

This data frame contains 60 rows and the following variables:

BPchange change in blood pressure relative to the start of the experiment.
Dose dose of Phenylbiguanide in micrograms.
Run label of run ("C1" to "C5", then "M1" to "M5").
Treatment placebo or the 5−HT₃ antagonist MDL 72222.
Animal label of animal used ("R1" to "R5").

Source

[The numerical data are not in the paper but were supplied by Professor Ludbrook]

References

rational

Rational Approximation

Description

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

Usage

rational(x, cycles = 10, max.denominator = 2000, ...)

Arguments

x
Any object of mode numeric. Missing values are now allowed.
cycles
The maximum number of steps to be used in the continued fraction approximation process.
max.denominator
An early termination criterion. If any partial denominator exceeds max.denominator the continued fraction stops at that point.
... arguments passed to or from other methods.

Details

Each component is first expanded in a continued fraction of the form

\[ x = \text{floor}(x) + 1/(p_1 + 1/(p_2 + \ldots)) \]

where \( p_1, p_2, \ldots \) are positive integers, terminating either at cycles terms or when a \( p_j > \text{max.denominator} \). The continued fraction is then re-arranged to retrieve the numerator and denominator as integers and the ratio returned as the value.

Value

A numeric object with the same attributes as x but with entries rational approximations to the values. This effectively rounds relative to the size of the object and replaces very small entries by zero.

See Also

fractions

Examples

X <- matrix(runif(25), 5, 5)
zapsmall(solve(X, X/5)) # print near-zeroes as zero
rational(solve(X, X/5))
renumerate

Convert a Formula Transformed by ‘denumerate’

Description

`denumerate` converts a formula written using the conventions of `loglm` into one that `terms` is able to process. `renumerate` converts it back again to a form like the original.

Usage

`renumerate(x)`

Arguments

- `x`: A formula, normally as modified by `denumerate`.

Details

This is an inverse function to `denumerate`. It is only needed since `terms` returns an expanded form of the original formula where the non-marginal terms are exposed. This expanded form is mapped back into a form corresponding to the one that the user originally supplied.

Value

A formula where all variables with names of the form `.vn`, where `n` is an integer, converted to numbers, `n`, as allowed by the formula conventions of `loglm`.

See Also

`denumerate`

Examples

```r
renumerate(~(1+2+3)^3 + a/b)
## ~ (.v1 + .v2 + .v3)^3 + a/b
renumerate(~.Last.value)
## ~ (1 + 2 + 3)^3 + a/b
```

r1m

Robust Fitting of Linear Models

Description

Fit a linear model by robust regression using an M estimator.
Usage

rlm(x, ...)

## S3 method for class 'formula'
rlm(formula, data, weights, ..., subset, na.action,
    method = c("M", "MM", "model.frame"),
    wt.method = c("inv.var", "case"),
    model = TRUE, x.ret = TRUE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
rlm(x, y, weights, ..., w = rep(1, nrow(x)),
    init = "ls", psi = psi.huber,
    scale.est = c("MAD", "Huber", "proposal 2"), k2 = 1.345,
    method = c("M", "MM"), wt.method = c("inv.var", "case"),
    maxit = 20, acc = 1e-4, test.vec = "resid", lqs.control = NULL)

psi.huber(u, k = 1.345, deriv = 0)
psi.hampel(u, a = 2, b = 4, c = 8, deriv = 0)
psi.bisquare(u, c = 4.685, deriv = 0)

Arguments

formula a formula of the form \( y \sim x_1 + x_2 + \ldots \).
data data frame from which variables specified in formula are preferentially to be taken.
weights a vector of prior weights for each case.
subset An index vector specifying the cases to be used in fitting.
na.action A function to specify the action to be taken if NAs are found. The 'factory-fresh' default action in R is na.omit, and can be changed by options(na.action=).
x a matrix or data frame containing the explanatory variables.
y the response: a vector of length the number of rows of x.
method currently either M-estimation or MM-estimation or (for the formula method only) find the model frame. MM-estimation is M-estimation with Tukey’s bi-weight initialized by a specific S-estimator. See the ‘Details’ section.
wt.method are the weights case weights (giving the relative importance of case, so a weight of 2 means there are two of these) or the inverse of the variances, so a weight of two means this error is half as variable?
model should the model frame be returned in the object?
x.ret should the model matrix be returned in the object?
y.ret should the response be returned in the object?
contrasts optional contrast specifications: see lm.
w (optional) initial down-weighting for each case.
init (optional) initial values for the coefficients OR a method to find initial values OR the result of a fit with a coef component. Known methods are "ls" (the default) for an initial least-squares fit using weights weights, and "lts" for an unweighted least-trimmed squares fit with 200 samples.
psi the psi function is specified by this argument. It must give (possibly by name) a function \( g(x, \ldots, \text{deriv}) \) that for \text{deriv}=0 returns \( \psi(x)/x \) and for \text{deriv}=1 returns \( \psi'(x) \). Tuning constants will be passed in via \ldots
scale.est  method of scale estimation: re-scaled MAD of the residuals (default) or Huber’s proposal 2 (which can be selected by either "Huber" or "proposal 2").

k2  tuning constant used for Huber proposal 2 scale estimation.

maxit  the limit on the number of IWLS iterations.

acc  the accuracy for the stopping criterion.

test.vec  the stopping criterion is based on changes in this vector.

...  additional arguments to be passed to rlm.default or to the psi function.

lqs.control  An optional list of control values for lqs.

u  numeric vector of evaluation points.

k, a, b, c  tuning constants.

deriv  0 or 1: compute values of the psi function or of its first derivative.

Details

Fitting is done by iterated re-weighted least squares (IWLS).
Psi functions are supplied for the Huber, Hampel and Tukey bisquare proposals as psi.huber, psi.hampel and psi.bisquare. Huber’s corresponds to a convex optimization problem and gives a unique solution (up to collinearity). The other two will have multiple local minima, and a good starting point is desirable.

Selecting method = "MM" selects a specific set of options which ensures that the estimator has a high breakdown point. The initial set of coefficients and the final scale are selected by an S-estimator with k0 = 1.548; this gives (for n \gg p) breakdown point 0.5. The final estimator is an M-estimator with Tukey’s biweight and fixed scale that will inherit this breakdown point provided c > k0; this is true for the default value of c that corresponds to 95% relative efficiency at the normal. Case weights are not supported for method = "MM".

Value

An object of class "rlm" inheriting from "lm". Note that the df.residual component is deliberately set to NA to avoid inappropriate estimation of the residual scale from the residual mean square by "lm" methods.

The additional components not in an lm object are

s  the robust scale estimate used

w  the weights used in the IWLS process

psi  the psi function with parameters substituted

conv  the convergence criteria at each iteration

converged  did the IWLS converge?

wresid  a working residual, weighted for "inv.var" weights only.

References

rms.curv

Description
Calculates the root mean square parameter effects and intrinsic relative curvatures, \( \theta \) and \( \iota \), for a fitted nonlinear regression, as defined in Bates & Watts, section 7.3, p. 253ff

Usage
rms.curv(obj)

Arguments
obj Fitted model object of class "nls". The model must be fitted using the default algorithm.

Details
The method of section 7.3.1 of Bates & Watts is implemented. The function deriv3 should be used to generate a model function with first derivative (gradient) matrix and second derivative (Hessian) array attributes. This function should then be used to fit the nonlinear regression model.

A print method, print.rms.curv, prints the pc and ic components only, suitably annotated.

If either pc or ic exceeds some threshold (0.3 has been suggested) the curvature is unacceptably high for the planar assumption.

Value
A list of class rms.curv with components pc and ic for parameter effects and intrinsic relative curvatures multiplied by \( \sqrt{F} \), ct and ci for \( \theta \) and \( \iota \) (unmultiplied), and C the C-array as used in section 7.3.1 of Bates & Watts.

## Intrinsic: c*omega x sqrt(F) = 0.092

rnegbin Simulate Negative Binomial Variates

Description

Function to generate random outcomes from a Negative Binomial distribution, with mean \( \mu \) and variance \( \mu + \mu^2/\theta \).

Usage

rnegbin(n, mu = n, theta = stop("'theta' must be specified"))

Arguments

n
  If a scalar, the number of sample values required. If a vector, length(n) is the
  number required and n is used as the mean vector if mu is not specified.

mu
  The vector of means. Short vectors are recycled.

theta
  Vector of values of the theta parameter. Short vectors are recycled.

Details

The function uses the representation of the Negative Binomial distribution as a continuous mixture of Poisson distributions with Gamma distributed means. Unlike \texttt{rnbinom} the index can be arbitrary.

Value

Vector of random Negative Binomial variate values.

Side Effects

Changes \texttt{.Random.seed} in the usual way.

Examples

# Negative Binomials with means fitted(fm) and theta = 4.5
fm <- glm.nb(Days ~ ., data = quine)
dummy <- rnegbin(fitted(fm), theta = 4.5)
Road Accident Deaths in US States

Description
A data frame with the annual deaths in road accidents for half the US states.

Usage
road

Format
Columns are:
state name.
deaths number of deaths.
drivers number of drivers (in 10,000s).
popden population density in people per square mile.
rural length of rural roads, in 1000s of miles.
temp average daily maximum temperature in January.
fuel fuel consumption in 10,000,000 US gallons per year.

Source

Numbers of Rotifers by Fluid Density

Description
The data give the numbers of rotifers falling out of suspension for different fluid densities. There are two species, pm *Polyarthra major* and kc, *Keratella cochlearis* and for each species the number falling out and the total number are given.

Usage
rotifer

Format

density specific density of fluid.
pm. y number falling out for *P. major*.
pt. total total number of *P. major*.
kc. y number falling out for *K. cochlearis*.
kc. tot total number of *K. cochlearis*.

Source
Description

Data frame from accelerated testing of tyre rubber.

Usage

Rubber

Format

- loss: the abrasion loss in gm/hr.
- hard: the hardness in Shore units.
- tens: tensile strength in kg/sq m.

Source

References

Description

One form of non-metric multidimensional scaling.

Usage

```r
sammon(d, y = cmdscale(d, k), k = 2, niter = 100, trace = TRUE,
    magic = 0.2, tol = 1e-4)
```
Arguments

d distance structure of the form returned by dist, or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. This can contain missing values.

y An initial configuration. If none is supplied, cmdscale is used to provide the classical solution. (If there are missing values in d, an initial configuration must be provided.) This must not have duplicates.

k The dimension of the configuration.
niter The maximum number of iterations.
trace Logical for tracing optimization. Default TRUE.
magic initial value of the step size constant in diagonal Newton method.
tol Tolerance for stopping, in units of stress.

Details

This chooses a two-dimensional configuration to minimize the stress, the sum of squared differences between the input distances and those of the configuration, weighted by the distances, the whole sum being divided by the sum of input distances to make the stress scale-free.

An iterative algorithm is used, which will usually converge in around 50 iterations. As this is necessarily an \(O(n^2)\) calculation, it is slow for large datasets. Further, since the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine. In this release the algorithm has been modified by adding a step-length search (magic) to ensure that it always goes downhill.

Value

Two components:

- points A two-column vector of the fitted configuration.
- stress The final stress achieved.

Side Effects

If trace is true, the initial stress and the current stress are printed out every 10 iterations.

**Snail Mortality Data**

**Description**

Groups of 20 snails were held for periods of 1, 2, 3 or 4 weeks in carefully controlled conditions of temperature and relative humidity. There were two species of snail, A and B, and the experiment was designed as a 4 by 3 by 4 by 2 completely randomized design. At the end of the exposure time the snails were tested to see if they had survived; the process itself is fatal for the animals. The object of the exercise was to model the probability of survival in terms of the stimulus variables, and in particular to test for differences between species.

The data are unusual in that in most cases fatalities during the experiment were fairly small.

**Usage**

`snails`
**Format**

The data frame contains the following components:

- **Species**: snail species A (1) or B (2).
- **Exposure**: exposure in weeks.
- **Rel.Hum**: relative humidity (4 levels).
- **Temp**: temperature, in degrees Celsius (3 levels).
- **Deaths**: number of deaths.
- **N**: number of snails exposed.

stepAIC

Choose a model by AIC in a Stepwise Algorithm

Description
Performs stepwise model selection by AIC.

Usage
stepAIC(object, scope, scale = 0, direction = c("both", "backward", "forward"), trace = 1, keep = NULL, steps = 1000, use.start = FALSE, k = 2, ...)

Arguments

object an object representing a model of an appropriate class. This is used as the initial model in the stepwise search.
scope defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components upper and lower, both formulae. See the details for how to specify the formulae and how they are used.
scale used in the definition of the AIC statistic for selecting the models, currently only for \texttt{lm} and \texttt{aov} models (see \texttt{extractAIC} for details).
direction the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the scope argument is missing the default for direction is "backward".
trace if positive, information is printed during the running of stepAIC. Larger values may give more information on the fitting process.
keep a filter function whose input is a fitted model object and the associated aic statistic, and whose output is arbitrary. Typically keep will select a subset of the components of the object and return them. The default is not to keep anything.
steps the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.
use.start if true the updated fits are done starting at the linear predictor for the currently selected model. This may speed up the iterative calculations for \texttt{glm} (and other fits), but it can also slow them down. Not used in \texttt{R}.
k the multiple of the number of degrees of freedom used for the penalty. Only \( k = 2 \) gives the genuine AIC: \( k = \log(n) \) is sometimes referred to as BIC or SBC.
...
any additional arguments to \texttt{extractAIC}. (None are currently used.)
Details

The set of models searched is determined by the `scope` argument. The right-hand-side of its lower component is always included in the model, and right-hand-side of the model is included in the upper component. If `scope` is a single formula, it specifies the upper component, and the lower model is empty. If `scope` is missing, the initial model is used as the upper model.

Models specified by `scope` can be templates to update objects as used by `update.formula`.

There is a potential problem in using `glm` fits with a variable `scale`, as in that case the deviance is not simply related to the maximized log-likelihood. The `glm` method for `extractAIC` makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The `binomial` and `poisson` families have fixed `scale` by default and do not correspond to a particular maximum-likelihood problem for variable `scale`.)

Where a conventional deviance exists (e.g. for `lm`, `aov` and `glm` fits) this is quoted in the analysis of variance table: it is the unscaled deviance.

Value

The stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).

Note

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and an `na.action` other than `na.fail` is used (as is the default in R). We suggest you remove the missing values first.

Examples

```r
quine.hi <- aov(log(Days + 2.5) ~ .^4, quine)
quine.nxt <- update(quine.hi, . ~ . - Eth:Sex:Age:Lrn)
quine.stp <- stepAIC(quine.nxt,
    scope = list(upper = ~Eth*Sex*Age*Lrn, lower = ~1),
    trace = FALSE)
quine.stp$anova

cpus1 <- cpus
for(v in names(cpus)[2:7])
    cpus1[[v]] <- cut(cpus[[v]], unique(quantile(cpus[[v]])),
                      include.lowest = TRUE)
cpus0 <- cpus1[, 2:8]  # excludes names, authors' predictions
cpus.samp <- sample(1:209, 100)
cpus.lm <- lm(log10(perf) ~ ., data = cpus1[cpus.samp,2:8])
```
The Stormer Viscometer Data

Description

The stormer viscometer measures the viscosity of a fluid by measuring the time taken for an inner cylinder in the mechanism to perform a fixed number of revolutions in response to an actuating weight. The viscometer is calibrated by measuring the time taken with varying weights while the mechanism is suspended in fluids of accurately known viscosity. The data comes from such a calibration, and theoretical considerations suggest a nonlinear relationship between time, weight and viscosity, of the form

\[ \text{Time} = \frac{B1 \times \text{Viscosity}}{(\text{Weight} - B2) + E} \]

where B1 and B2 are unknown parameters to be estimated, and E is error.

Usage

stormer

Format

The data frame contains the following components:

- **Viscosity**: viscosity of fluid.
- **Wt**: actuating weight.
- **Time**: time taken.

studres

Extract Studentized Residuals from a Linear Model

Description
The Studentized residuals. Like standardized residuals, these are normalized to unit variance, but the Studentized version is fitted ignoring the current data point. (They are sometimes called jackknifed residuals).

Usage
studres(object)

Arguments
object any object representing a linear model.

Value
The vector of appropriately transformed residuals.

References

See Also
residuals, stdres

summary.loglm
Summary Method Function for Objects of Class 'loglm'

Description
Returns a summary list for log-linear models fitted by iterative proportional scaling using loglm.

Usage
## S3 method for class 'loglm'
summary(object, fitted = FALSE, ...)

Arguments
object a fitted loglm model object.
fitted if TRUE return observed and expected frequencies in the result. Using fitted = TRUE may necessitate re-fitting the object.
... arguments to be passed to or from other methods.
This function is a method for the generic function summary() for class "loglm". It can be invoked by calling summary(x) for an object x of the appropriate class, or directly by calling summary.loglm(x) regardless of the class of the object.

a list is returned for use by print.summary.loglm. This has components

- **formula**: the formula used to produce object
- **tests**: the table of test statistics (likelihood ratio, Pearson) for the fit.
- **oe**: if fitted = TRUE, an array of the observed and expected frequencies, otherwise NULL.

Identical to summary.glm, but with three lines of additional output: the ML estimate of theta, its standard error, and twice the log-likelihood function.

**Usage**

```r
## S3 method for class 'negbin'
summary(object, dispersion = 1, correlation = FALSE, ...)
```

**Arguments**

- **object**: fitted model object of class negbin inheriting from glm and lm. Typically the output of glm.nb.
- **dispersion**: as for summary.glm, with a default of 1.
- **correlation**: as for summary.glm.
- **...**: arguments passed to or from other methods.

**Details**

summary.glm is used to produce the majority of the output and supply the result. This function is a method for the generic function summary() for class "negbin". It can be invoked by calling summary(x) for an object x of the appropriate class, or directly by calling summary.negbin(x) regardless of the class of the object.
Value

As for `summary.glm`; the additional lines of output are not included in the resultant object.

Side Effects

A summary table is produced as for `summary.glm`, with the additional information described above.

References

**summary.rlm**  
Summary Method for Robust Linear Models

Description

`summary` method for objects of class "rlm"

Usage

```r
## S3 method for class 'rlm'
summary(object, method = c("XtX", "XtWX"), correlation = FALSE, ...)
```

Arguments

- **object**: the fitted model. This is assumed to be the result of some fit that produces an object inheriting from the class `rlm`, in the sense that the components returned by the `rlm` function will be available.
- **method**: Should the weighted (by the IWLS weights) or unweighted cross-products matrix be used?
- **correlation**: logical. Should correlations be computed (and printed)?
- **...**: arguments passed to or from other methods.

Details

This function is a method for the generic function `summary()` for class "rlm". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.rlm(x)` regardless of the class of the object.
survey

Value

If printing takes place, only a null value is returned. Otherwise, a list is returned with the following components. Printing always takes place if this function is invoked automatically as a method for the summary function.

- **correlation**: The computed correlation coefficient matrix for the coefficients in the model.
- **cov.unscaled**: The unscaled covariance matrix; i.e., a matrix such that multiplying it by an estimate of the error variance produces an estimated covariance matrix for the coefficients.
- **sigma**: The scale estimate.
- **stddev**: A scale estimate used for the standard errors.
- **df**: The number of degrees of freedom for the model and for residuals.
- **coefficients**: A matrix with three columns, containing the coefficients, their standard errors and the corresponding t statistic.
- **terms**: The terms object used in fitting this model.

References

- `summary`

Examples

```r
summary(rlm(calls ~ year, data = phones, maxit = 50))
```

---

**survey**  
**Student Survey Data**

Description

This data frame contains the responses of 237 Statistics I students at the University of Adelaide to a number of questions.

Usage

- `survey`

Format

The components of the data frame are:

- **sex**: The sex of the student. (Factor with levels "Male" and "Female").
- **wr.hnd**: span (distance from tip of thumb to tip of little finger of spread hand) of writing hand, in centimetres.
- **nw.hnd**: span of non-writing hand.
- **w.hnd**: writing hand of student. (Factor, with levels "Left" and "Right").
Fold  "Fold your arms! Which is on top" (Factor, with levels "R on L", "L on R", "Neither").

Pulse  pulse rate of student (beats per minute).

Clap  'Clap your hands! Which hand is on top?' (Factor, with levels "Right", "Left", "Neither").

Exer  how often the student exercises. (Factor, with levels "Freq" (frequently), "Some", "None").

Smoke  how much the student smokes. (Factor, levels "Heavy", "Regul" (regularly), "Occas" (occasionally), "Never").

Height  height of the student in centimetres.

M.I  whether the student expressed height in imperial (feet/inches) or metric (centimetres/metres) units. (Factor, levels "Metric", "Imperial").

Age  age of the student in years.

synth.tr  Synthetic Classification Problem

Description

The synth.tr data frame has 250 rows and 3 columns. The synth.te data frame has 100 rows and 3 columns. It is intended that synth.tr be used from training and synth.te for testing.

Usage

synth.tr
synth.te

Format

These data frames contains the following columns:

xs  x-coordinate
ys  y-coordinate
yc  class, coded as 0 or 1.

Source

theta.md

Estimate theta of the Negative Binomial

Description

Given the estimated mean vector, estimate theta of the Negative Binomial Distribution.

Usage

theta.md(y, mu, dfr, weights, limit = 20, eps = .Machine$double.eps^0.25)
theta.ml(y, mu, n, weights, limit = 10, eps = .Machine$double.eps^0.25, trace = FALSE)
theta.mm(y, mu, dfr, weights, limit = 10, eps = .Machine$double.eps^0.25)

Arguments

y Vector of observed values from the Negative Binomial.
mu Estimated mean vector.
n Number of data points (defaults to the sum of weights)
dfr Residual degrees of freedom (assuming theta known). For a weighted fit this is the sum of the weights minus the number of fitted parameters.
weights Case weights. If missing, taken as 1.
limit Limit on the number of iterations.
eps Tolerance to determine convergence.
trace logical: should iteration progress be printed?

Details

theta.md estimates by equating the deviance to the residual degrees of freedom, an analogue of a moment estimator.
theta.ml uses maximum likelihood.
theta.mm calculates the moment estimator of theta by equating the Pearson chi-square \( \sum (y - \mu)^2 / (\mu + \mu^2 / \theta) \) to the residual degrees of freedom.

Value

The required estimate of theta, as a scalar. For theta.ml, the standard error is given as attribute "SE".

theta.mm(quine$Days, fitted(quine.nb), dfr = df.residual(quine.nb))

# weighted example
yeast <- data.frame(cbind(numbers = 0:5, fr = c(213, 128, 37, 18, 3, 1)))
fit <- glm.nb(numbers ~ 1, weights = fr, data = yeast)
summary(fit)
mu <- fitted(fit)
theta.md(yeast$numbers, mu, dfr = 399, weights = yeast$fr)
theta.ml(yeast$numbers, mu, limit = 15, weights = yeast$fr)
theta.mm(yeast$numbers, mu, dfr = 399, weights = yeast$fr)

topo  

Spatial Topographic Data

Description

The topo data frame has 52 rows and 3 columns, of topographic heights within a 310 feet square.

Usage

topo

Format

This data frame contains the following columns:

x  x coordinates (units of 50 feet)
y  y coordinates (units of 50 feet)
z  heights (feet)

Source

Davis, J.C. (1973) *Statistics and Data Analysis in Geology*. Wiley.

References

An experiment was performed in Sweden in 1961–2 to assess the effect of a speed limit on the motorway accident rate. The experiment was conducted on 92 days in each year, matched so that day j in 1962 was comparable to day j in 1961. On some days the speed limit was in effect and enforced, while on other days there was no speed limit and cars tended to be driven faster. The speed limit days tended to be in contiguous blocks.

This data frame contains the following columns:

- **year**: 1961 or 1962.
- **day**: of year.
- **limit**: was there a speed limit?
- **y**: traffic accident count for that day.

**truehist**

*Plot a Histogram*

- Creates a histogram on the current graphics device.
Arguments

data numeric vector of data for histogram. Missing values (NAs) are allowed and omitted.

nbins The suggested number of bins. Either a positive integer, or a character string naming a rule: "Scott" or "Freedman-Diaconis" or "FD". (Case is ignored.)

h The bin width, a strictly positive number (takes precedence over nbins).

x0 Shift for the bins - the breaks are at x0 + h * (\ldots, -1, 0, 1, \ldots)

breaks The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).

prob If true (the default) plot a true histogram. The vertical axis has a relative frequency density scale, so the product of the dimensions of any panel gives the relative frequency. Hence the total area under the histogram is 1 and it is directly comparable with most other estimates of the probability density function. If false plot the counts in the bins.

xlim The limits for the x-axis.

ymax The upper limit for the y-axis.

col The colour for the bar fill: the default is colour 5 in the default R palette.

xlab label for the plot x-axis. By default, this will be the name of data.

bty The box type for the plot - defaults to none.

... additional arguments to rect or plot.

Details

This plots a true histogram, a density estimate of total area 1. If breaks is specified, those breakpoints are used. Otherwise if h is specified, a regular grid of bins is used with width h. If neither breaks nor h is specified, nbins is used to select a suitable h.

Side Effects

A histogram is plotted on the current device.

The Effect of Punishment Regimes on Crime Rates

Description

Criminologists are interested in the effect of punishment regimes on crime rates. This has been studied using aggregate data on 47 states of the USA for 1960 given in this data frame. The variables seem to have been re-scaled to convenient numbers.

Usage

UScrime

Format

This data frame contains the following columns:

- **M** percentage of males aged 14–24.
- **So** indicator variable for a Southern state.
- **Ed** mean years of schooling.
- **Po1** police expenditure in 1960.
- **Po2** police expenditure in 1959.
LF labour force participation rate.
M_F number of males per 1000 females.
Pop state population.
NW number of non-whites per 1000 people.
U1 unemployment rate of urban males 14–24.
U2 unemployment rate of urban males 35–39.
GDP gross domestic product per head.
Ineq income inequality.
Prob probability of imprisonment.
Time average time served in state prisons.
y rate of crimes in a particular category per head of population.

| whiteside | House Insulation: Whiteside's Data |

Description
Mr Derek Whiteside of the UK Building Research Station recorded the weekly gas consumption and average external temperature at his own house in south-east England for two heating seasons, one of 26 weeks before, and one of 30 weeks after cavity-wall insulation was installed. The object of the exercise was to assess the effect of the insulation on gas consumption.

Usage
whiteside

Format
The whiteside data frame has 56 rows and 3 columns:

Insul  A factor, before or after insulation.

Temp  Purportedly the average outside temperature in degrees Celsius. (These values is far too low for any 56-week period in the 1960s in South-East England. It might be the weekly average of daily minima.)

Gas  The weekly gas consumption in 1000s of cubic feet.
Source

A data set collected in the 1960s by Mr Derek Whiteside of the UK Building Research Station. Reported by

References

Examples

```r
require(lattice)
xypplot(Gas ~ Temp | Insul, whiteside, panel =
  function(x, y, ...) {
    panel.xyplot(x, y, ...)
    panel.lmline(x, y, ...)
  },
  xlab = "Average external temperature (deg. C)",
ylab = "Gas consumption (1000 cubic feet)", asp = "xy",
  strip = function(...) strip.default(..., style = 1))

gasB <- lm(Gas ~ Temp, whiteside, subset = Insul=="Before")
gasA <- update(gasB, subset = Insul=="After")
summary(gasB)
summary(gasA)
gasBA <- lm(Gas ~ Insul/Temp - 1, whiteside)
summary(gasBA)
gasQ <- lm(Gas ~ Insul/(Temp + I(Temp^2)) - 1, whiteside)
coef(summary(gasQ))
gasPR <- lm(Gas ~ Insul + Temp, whiteside)

```

width.SJ

*Bandwidth Selection by Pilot Estimation of Derivatives*

Description

Uses the method of Sheather & Jones (1991) to select the bandwidth of a Gaussian kernel density estimator.

Usage

```r
width.SJ(x, nb = 1000, lower, upper, method = c("ste", "dpi"))
```
Arguments

x a numeric vector
nb number of bins to use.
upper, lower range over which to search for solution if method = "ste".
method Either "ste" ("solve-the-equation") or "dpi" ("direct plug-in").

Value

a bandwidth.

References

See Also

**write.matrix**

*Write a Matrix or Data Frame*

Description

Writes a matrix or data frame to a file or the console, using column labels and a layout respecting columns.

Usage

```
write.matrix(x, file = "", sep = " ", blocksize)
```

Arguments

x matrix or data frame.
file name of output file. The default ("") is the console.
sep The separator between columns.
blocksize If supplied and positive, the output is written in blocks of blocksize rows. Choose as large as possible consistent with the amount of memory available.
wtloss

Details
If x is a matrix, supplying blocksize is more memory-efficient and enables larger matrices to be written, but each block of rows might be formatted slightly differently.
If x is a data frame, the conversion to a matrix may negate the memory saving.

Side Effects
A formatted file is produced, with column headings (if x has them) and columns of data.

wttloss.fm
plot(wtloss)
with(wtloss, lines(Days, fitted(wtloss.fm)))
```
Chapter 17

The Matrix package

abIndex-class  

Class "abIndex" of Abstract Index Vectors

Description

The "abIndex" class, short for "Abstract Index Vector", is used for dealing with large index vectors more efficiently, than using integer (or numeric) vectors of the kind 2:1000000 or c(0:1e5, 1000:1e6).

Note that the current implementation details are subject to change, and if you consider working with these classes, please contact the package maintainers (packageDescription("Matrix")$Maintainer).

Objects from the Class

Objects can be created by calls of the form new("abIndex", ...), but more easily and typically either by as(x, "abIndex") where x is an integer (valued) vector, or directly by abIseq() and combination c(...).

Slots

kind: a character string, one of ("int32", "double", "rleDiff"), denoting the internal structure of the abIndex object.

x: Object of class "numLike"; is used (i.e., not of length 0) only if the object is not compressed, i.e., currently exactly when kind != "rleDiff".

rle0: object of class "rleDiff", used for compression via rle.

Methods

as.numeric, as.integer, as.vector signature(x = "abIndex"): ...

[ signature(x = "abIndex", i = "index", j = "ANY", drop = "ANY"): ...

coerce signature(from = "numeric", to = "abIndex"): ...

coerce signature(from = "abIndex", to = "numeric"): ...

coerce signature(from = "abIndex", to = "integer"): ...

coerce signature(from = "abIndex", to = "integer"): ...

length signature(x = "abIndex"): ...
```
Ops signature(e1 = "numeric", e2 = "abIndex"): These and the following
arithmetic and logic operations are not yet implemented; see Ops for
a list of these (S4) group methods.

Ops signature(e1 = "abIndex", e2 = "abIndex"): ...

Ops signature(e1 = "abIndex", e2 = "numeric"): ...

Summary signature(x = "abIndex"): ...

show ("abIndex"): simple show method, building on show(<rleDiff>).
is.na ("abIndex"): works analogously to regular vectors.
is.finite, is.infinite ("abIndex"): ditto.
```

**Note**

This is currently experimental and not yet used for our own code. Please contact us (packageDescription("Matrix")$Maintainer), if you plan to make use of this class.

Partly builds on ideas and code from Jens Oehlschlaegel, as implemented (around 2008, in the GPL'ed part of) package ff.

**See Also**

* rle (base) which is used here: numeric

**Examples**

```r
showClass("abIndex")
ii <- c(-3:40, 20:70)
str(ai <- as(ii, "abIndex"))# note
ai # -> show() method

stopifnot(identical(-3:20,
as(abiseq(-3,20), "vector")))
```

---

### abiseq

**Sequence Generation of "abIndex", Abstract Index Vectors**

**Description**

Generation of abstract index vectors, i.e., objects of class "abIndex". `abiseq()` is designed to work entirely like seq, but producing "abIndex" vectors. `abiseq1()` is its basic building block, where `abiseq1(n,m)` corresponds to n:m. `c(x, ...)` will return an "abIndex" vector, when x is one.

**Usage**

```r
abiseq1(from = 1, to = 1)
abiseq (from = 1, to = 1, by = ((to - from)/(length.out - 1)),
       length.out = NULL, along.with = NULL)

## S3 method for class 'abIndex'
c(...)
```
Arguments

- from, to: the starting and (maximal) end value of the sequence.
- by: number: increment of the sequence.
- length.out: desired length of the sequence. A non-negative number, which for seq and seq.int will be rounded up if fractional.
- along.with: take the length from the length of this argument.
- ...: in general an arbitrary number of R objects; here, when the first is an "abIndex" vector, these arguments will be concatenated to a new "abIndex" object.

Value

An abstract index vector, i.e., object of class "abIndex".

See Also

the class abIndex documentation; rep2abI() for another constructor; rle (base).

Examples

```r
stopifnot(identical(-3:20,
    as(abIseq(-3,20), "vector")))
try( ## (arithmetic) not yet implemented
    abIseq(1, 50, by = 3)
)
```

Description

The basic R functions all and any now have methods for Matrix objects and should behave as for matrix ones.

Methods

- all signature(x = "Matrix", ..., na.rm = FALSE):...
- any signature(x = "Matrix", ..., na.rm = FALSE):...
- all signature(x = "ldenseMatrix", ..., na.rm = FALSE):...
- all signature(x = "lsparseMatrix", ..., na.rm = FALSE):...

Examples

```r
M <- Matrix(1:12 +0, 3,4)
all(M >= 1) # TRUE
any(M < 0 ) # FALSE
MN <- M; MN[2,3] <- NA; MN
all(MN >= 0) # NA
any(MN < 0 ) # NA
any(MN < 0, na.rm = TRUE) # -> FALSE
```
all.equal-methods  Matrix Package Methods for Function all.equal()

Description

Methods for function `all.equal()` (from R package `base`) are defined for all `Matrix` classes.

Methods

- `target = "Matrix", current = "Matrix"
- `target = "ANY", current = "Matrix"
- `target = "Matrix", current = "ANY"` these three methods are simply using `all.equal.numeric` directly and work via `as.vector()`.

There are more methods, notably also for "sparseVector"'s, see `showMethods("all.equal")`.

Examples

```r
showMethods("all.equal")

(A <- spMatrix(3,3, i= c(1:3,2:1), j=c(3:1,1:2), x = 1:5))
ex <- expand(lu <- lu(A))
stopifnot( all.equal(as(A[lu.@p + 1L, lu.@q + 1L], "CsparseMatrix"),
     lu.@L %*% lu.@U),
     with(ex, all.equal(as(P %*% A %*% Q, "CsparseMatrix"),
     with(ex, all.equal(as(A, "CsparseMatrix"),
     t(P) %*% L %*% U %*% t(Q))))
```

atomicVector-class  Virtual Class "atomicVector" of Atomic Vectors

Description

The class "atomicVector" is a virtual class containing all atomic vector classes of base R, as also implicitly defined via `is.atomic`.

Objects from the Class

A virtual Class: No objects may be created from it.

Methods

In the `Matrix` package, the "atomicVector" is used in signatures where typically "old-style" "matrix" objects can be used and can be substituted by simple vectors.

Extends

The atomic classes "logical", "integer", "double", "numeric", "complex", "raw" and "character" are extended directly. Note that "numeric" already contains "integer" and "double", but we want all of them to be direct subclasses of "atomicVector".
Author(s)

Martin Maechler

See Also

is.atomic, integer, numeric, complex, etc.

Examples

showClass("atomicVector")

Description

Returns a new matrix formed by extracting the lower triangle (tril) or the upper triangle (triu) or a general band relative to the diagonal (band), and setting other elements to zero. The general forms of these functions include integer arguments to specify how many diagonal bands above or below the main diagonal are not set to zero.

Usage

band(x, k1, k2, ...)  
tril(x, k = 0, ...)  
triu(x, k = 0, ...)

Arguments

x                         a matrix-like object
k1, k2                    integers specifying the diagonal bands that will not be set to zero. These are given relative to the main diagonal, which is k=0. A negative value of k indicates a diagonal below the main diagonal and a positive value indicates a diagonal above the main diagonal.
...

Value

An object of an appropriate matrix class. The class of the value of tril or triu inherits from triangularMatrix when appropriate. Note that the result is of class sparseMatrix only if x is.

Methods

x = "CsparseMatrix"  method for compressed, sparse, column-oriented matrices.

x = "TsparseMatrix"  method for sparse matrices in triplet format.

x = "RsparseMatrix"  method for compressed, sparse, row-oriented matrices.

x = "ddenseMatrix"  method for dense numeric matrices, including packed numeric matrices.

See Also

bandSparse for the construction of a banded sparse matrix directly from its non-zero diagonals.
Examples

```r
## A random sparse matrix :
set.seed(7)
m <- matrix(0, 5, 5)
m[sample(length(m), size = 14)] <- rep(1:9, length=14)
(mm <- as(m, "CsparseMatrix"))

tril(mm)  # lower triangle
tril(mm, -1)  # strict lower triangle
triu(mm, 1)  # strict upper triangle
band(mm, -1, 2)  # general band

(m5 <- Matrix(rnorm(25), nc = 5))
tril(m5)  # lower triangle
tril(m5, -1)  # strict lower triangle
triu(m5, 1)  # strict upper triangle
band(m5, -1, 2)  # general band

(m65 <- Matrix(rnorm(30), nc = 5))  # not square
triu(m65)  # result in not dtrMatrix unless square
(sm5 <- crossprod(m65))  # symmetric
  band(sm5, -1, 1)  # symmetric band preserves symmetry property
as(band(sm5, -1, 1), "sparseMatrix")  # often preferable
```

---

**bandSparse**

**Construct Sparse Banded Matrix from (Sup-/Super-) Diagonals**

**Description**

Construct a sparse banded matrix by specifying its non-zero sup- and super-diagonals.

**Usage**

`bandSparse(n, m = n, k, diagonals, symmetric = FALSE, giveCsparse = TRUE)`

**Arguments**

- `n, m` the matrix dimension \((n, m) = (nrow, ncol)\).
- `k` integer vector of “diagonal numbers”, with identical meaning as in `band(*, k)`.
- `diagonals` optional list of sub-/super- diagonals; if missing, the result will be a `pattern` matrix, i.e., inheriting from class `nMatrix`.
  - Diagonals can also be \(n' \times d\) matrix, where \(d \leq \text{length}(k)\) and \(n' \geq \text{min}(n, m)\). In that case, the sub-/super- diagonals are taken from the columns of diagonals, where only the first several rows will be used (typically) for off-diagonals.
- `symmetric` logical; if true the result will be symmetric (inheriting from class `symmetricMatrix`) and only the upper or lower triangle must be specified (via `k` and `diagonals`).
- `giveCsparse` logical indicating if the result should be a `CsparseMatrix` or a `TsparseMatrix`. The default, TRUE is very often more efficient subsequently, but not always.
Construct a Block Diagonal Matrix

Value

A sparse matrix (of class \texttt{CsparseMatrix}) of dimension \(n \times m\) with diagonal “bands” as specified.

See Also

\texttt{band}, for extraction of matrix bands; \texttt{bdiag, diag, sparseMatrix, Matrix}.

Examples

```r
diags <- list(1:30, 10*(1:20), 100*(1:20))
s1 <- bandSparse(13, k = -c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
s1
s2 <- bandSparse(13, k = c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
stopifnot(identical(s1, t(s2)), is(s1,"dsCMatrix"))

## a pattern Matrix of *full* (sub-)diagonals:
bk <- c(0:4, 7,9)
(s3 <- bandSparse(30, k = bk, symm = TRUE))

## If you want a pattern matrix, but with "sparse"-diagonals,
## you currently need to go via logical sparse:
lis <- lapply(list(rpois(20, 2), rpois(20,1), rpois(20,3)),function(x)c(1:3,2:3,3:2),as.logical)
(s4 <- bandSparse(20, k = bk, symm = TRUE, diag = lis))
(s4. <- as(drop0(s4), "nsparseMatrix"))

n <- 1e4
bk <- c(0:5, 7,11)
bMat <- matrix(1:8, n, 8, byrow=TRUE)
blis <- as.data.frame(bMat)
B <- bandSparse(n, k = bk, diag = blis)
Bs <- bandSparse(n, k = bk, diag = blis, symmetric=TRUE)
B [1:15, 1:30]
Bs[1:15, 1:30]

## can use a list *or* a matrix for specifying the diagonals:
stopifnot(identical(B, bandSparse(n, k = bk, diag = bMat)),
identical(Bs, bandSparse(n, k = bk, diag = bMat, symmetric=TRUE)))
```

Details

For non-trivial argument list, bdiag() calls .bdiag(). The latter maybe useful to programmers.

Value

A sparse matrix obtained by combining the arguments into a block diagonal matrix. The value of bdiag() inherits from class CsparseMatrix, whereas .bdiag() returns a TsparseMatrix.

Author(s)

Martin Maechler, built on a version posted by Berton Gunter to R-help; earlier versions have been posted by other authors, notably Scott Chasalow to S-news. Doug Bates’s faster implementation builds on TsparseMatrix objects.

See Also

Diagonal for constructing matrices of class diagonalMatrix, or kronecker which also works for "Matrix" inheriting matrices.

bandSparse constructs a banded sparse matrix from its non-zero sub-/super - diagonals.

Note that other CRAN R packages have own versions of bdiag() which return traditional matrices.

Examples

bdiag(matrix(1:4, 2), diag(3))
## combine "Matrix" class and traditional matrices:
bdiag(Diagonal(2), matrix(1:3, 3, 4), diag(3:2))

mlist <- list(1, 2:3, diag(x=5:3), 27, cbind(1,3:6), 100:101)
bdiag(mlist)
stopifnot(identical(bdiag(mlist),
   bdiag(lapply(mlist, as.matrix)))))

ml <- c(as(matrix((1:24)%% 11 == 0, 6,4),"nMatrix"),
   rep(list(Diagonal(2, x=TRUE)), 3))
mln <- c(ml, Diagonal(x = 1:3))
stopifnot(is(bdiag(ml), "lsparseMatrix"),
   is(bdiag(mln),"dsparseMatrix") )
Arguments

x          a symmetric square matrix.

...        potentially further arguments passed to methods.

Value

an object of class BunchKaufman, which can also be used as a (triangular) matrix directly.

Methods

Currently, only methods for dense numeric symmetric matrices are implemented.

x = "dspMatrix" uses Lapack routine dsytrf,

x = "dsyMatrix" uses Lapack routine dsytrf, computing the Bunch-Kaufman decomposition.

References

The original LAPACK source code, including documentation; http://www.netlib.org/lapack/
double/dsytrf.f and http://www.netlib.org/lapack-double/dsptrf.f

See Also

The resulting class, BunchKaufman. Related decompositions are the LU, lu, and the Cholesky, chol
(and for sparse matrices, Cholesky).

Examples

data(CAex)
dim(CAex)
isSymmetric(CAex)# TRUE
CAs <- as(CAex, "symmetricMatrix")
if(FALSE) # no method defined yet for *sparse* :
bk. <- BunchKaufman(CAs)
  ## does apply to *dense* symmetric matrices:
bkCA <- BunchKaufman(as(CAs, "denseMatrix"))
bkCA

image(bkCA)# shows how sparse it is, too
str(R.CA <- as(bkCA, "sparseMatrix"))
  ## an upper triangular 72x72 matrix with only 144 non-zero entries

CAex

Albers' example Matrix with "Difficult" Eigen Factorization

Description

An example of a sparse matrix for which eigen() seemed to be difficult, an unscaled version of this has been posted to the web, accompanying an E-mail to R-help (https://stat.ethz.ch/mailman/listinfo/r-help), by Casper J Albers, Open University, UK.

Usage

data(CAex)
Format

This is a $72 \times 72$ symmetric matrix with 216 non-zero entries in five bands, stored as sparse matrix of class `dgCMatrix`.

Details

In some versions of R, `eigen(CAex)` fell into an infinite loop (whereas `eigen(CAex, EISPACK=TRUE)` has been okay).

Examples

```r
data(CAex)
str(CAex)  # of class "dgCMatrix"

image(CAex)# -> it's a simple band matrix with 5 bands
## and the eigen values are basically 1 (42 times) and 0 (30 x):
zapsmall(ev <- eigen(CAex, EISPACK=TRUE, only.values=TRUE)$values)
## i.e., the matrix is symmetric, hence
sCA <- as(CAex, "symmetricMatrix")
## and
stopifnot(class(sCA) == "dsCMatrix",
  as(sCA, "matrix") == as(CAex, "matrix"))
```

Description

The base functions `cbind` and `rbind` are defined for an arbitrary number of arguments and hence have the first formal argument .... For that reason, S4 methods cannot easily be defined for binding together matrices inheriting from `Matrix`.

For that reason, `cbind2` and `rbind2` have been provided for binding together two matrices, and we have defined methods for these and the `Matrix`-matrices.

As a substitute for S4-enabled versions of `cbind` and `rbind`, you can use `cBind` and `rBind` with identical syntax and semantic in order to bind together multiple matrices ("matrix" or "Matrix" and vectors.

Usage

```r
cBind(..., deparse.level = 1)
rBind(..., deparse.level = 1)
```

Arguments

- `...` matrix-like R objects to be bound together, see `cbind` and `rbind`.
- `deparse.level` integer determining under which circumstances column and row names are built from the actual arguments' `expression`, see `cbind`.
Details

The implementation of these is recursive, calling \texttt{cbind2} or \texttt{rbind2} respectively, where these have methods defined and so should dispatch appropriately.

Value

typically a ‘matrix-like’ object of a similar class as the first argument in . . . .

Note that sometimes by default, the result is a \texttt{sparseMatrix} if one of the arguments is (even in the case where this is not efficient). In other cases, the result is chosen to be sparse when there are more zero entries than non-zero ones (as the default sparse in \texttt{Matrix()}).

Author(s)

Martin Maechler

See Also

\texttt{cbind2, cbind, Methods}.

Examples

\begin{verbatim}
(a <- matrix(c(2:1,1:2), 2,2))
cbind(0, rBind(a, 7)) # remains traditional matrix

D <- Diagonal(2)
cBind(4, a, D, -1, D, 0) # a sparse Matrix
\end{verbatim}
Arguments

x, object, a "CHMfactor" object (almost always the result of Cholesky()).

parent a "dsCMatrix" or "dgCMatrix" matrix object with the same nonzero pattern as the matrix that generated object. If parent is symmetric, of class "dsCMatrix", then object should be a decomposition of a matrix with the same nonzero pattern as parent. If parent is not symmetric then object should be the decomposition of a matrix with the same nonzero pattern as tcrossprod(parent).

Since Matrix version 1.0-8, other "sparseMatrix" matrices are coerced to dsparseMatrix and CsparseMatrix if needed.

mult a numeric scalar (default 0). mult times the identity matrix is (implicitly) added to parent or tcrossprod(parent) before updating the decomposition object.

... potentially further arguments to the methods.

Objects from the Class

Objects can be created by calls of the form new("dCHMsuper", ...) but are more commonly created via Cholesky(), applied to dsCMatrix or IsCMatrix objects.

For an introduction, it may be helpful to look at the expand() method and examples below.

Slots

of "CHMfactor" and all classes inheriting from it:

perm: An integer vector giving the 0-based permutation of the rows and columns chosen to reduce fill-in and for post-ordering.

colcount: Object of class "integer" ....

type: Object of class "integer" ....

Slots of the non virtual classes "[dl]CHM(super|simpl)":

p: Object of class "integer" of pointers, one for each column, to the initial (zero-based) index of elements in the column. Only present in classes that contain "CHMsimpl".

i: Object of class "integer" of length nzero (number of non-zero elements). These are the row numbers for each non-zero element in the matrix. Only present in classes that contain "CHMsimpl".

x: For the "d*" classes: "numeric" - the non-zero elements of the matrix.

Methods

isLDL (x) returns a logical indicating if x is an LDL' decomposition or (when FALSE) an LL' one.

coerce signature(from = "CHMfactor", to = "sparseMatrix") (or equivalently, to = "Matrix" or to = "triangularMatrix")

as(*, "sparseMatrix") returns the lower triangular factor L from the LL' form of the Cholesky factorization. Note that (currently) the factor from the LL' form is always returned, even if the "CHMfactor" object represents an LDL' decomposition. Furthermore, this is the factor after any fill-reducing permutation has been applied. See the expand method for obtaining both the permutation matrix, P, and the lower Cholesky factor, L.

coerce signature(from = "CHMfactor", to = "pMatrix") returns the permutation matrix P, representing the fill-reducing permutation used in the decomposition.
expand signature(x = "CHMfactor") returns a list with components P, the matrix representing the fill-reducing permutation, and L, the lower triangular Cholesky factor. The original positive-definite matrix A corresponds to the product \( A = P'LL'P \). Because of fill-in during the decomposition the product may apparently have more non-zeros than the original matrix, even after applying drop0 to it. However, the extra 'non-zeros' should be very small in magnitude.

image signature(x = "CHMfactor"): Plot the image of the lower triangular factor, L, from the decomposition. This method is equivalent to image(as(x, "sparseMatrix")) so the comments in the above description of the coerce method apply here too.

crossprod signature(a = "CHMfactor", b = "ddenseMatrix"), system = "*": The solve methods for a "CHMfactor" object take an optional third argument system whose value can be one of the character strings "A", "LDLt", "LD", "DLt", "L", "Lt", or "P". This argument describes the system to be solved. The default, "A", is to solve \( Ax = b \) for \( x \) where A is the sparse, positive-definite matrix that was factored to produce a. Analogously, system = "L" returns the solution \( x \) of \( Lx = b \). Similarly, for all system codes but "P" and "Pt" where, e.g., \( x \leftarrow \text{solve}(a, b, \text{system}="P") \) is equivalent to \( x \leftarrow P^{-1}b \). See also solve-methods.

determinant signature(x = "CHMfactor", logarithm = "logical") returns the determinant (or the logarithm of the determinant, if logarithm = TRUE, the default) of the factor \( L \) from the \( LL' \) decomposition (even if the decomposition represented by \( x \) is of the \( LDL' \) form (!)). This is the square root of the determinant (half the logarithm of the determinant when logarithm = TRUE) of the positive-definite matrix that was decomposed.

update signature(object = "CHMfactor"), parent. The update method requires an additional argument parent, which is either a "dsCMatrix" object, say \( A \) (with the same structure of nonzeros as the matrix that was decomposed to produce object) or a general "dgCMatrix", say \( M \), where \( A := MM' \) is used for \( A \). Further it provides an optional argument mult, a numeric scalar. This method updates the numeric values in object to the decomposition of \( A + ml \) where \( A \) is the matrix above (either the parent or \( MM' \)) and \( m \) is the scalar mult. Because only the numeric values are updated this method should be faster than creating and decomposing \( A + ml \). It is not uncommon to want, say, the determinant of \( A + ml \) for many different values of \( m \). This method would be the preferred approach in such cases.

See Also

Cholesky, also for examples; class dgCMatrix.

Examples

```r
## An example for the expand() method
n <- 1000; m <- 200; nnz <- 2000
set.seed(1)
M1 <- spMatrix(n, m,
  i = sample(n, nnz, replace = TRUE),
  j = sample(m, nnz, replace = TRUE),
  x = round(rnorm(nnz), 1))
XX <- crossprod(M1)  ## = M1'M1 = M'M where M <- t(M1)
CX <- Cholesky(XX)
isLDL(CX)
str(CX)  ## a "dCHMsimpl" object
r <- expand(CX)
L.P <- with(r, crossprod(L, P))  ## = L'P
```
chol <- crossprod(L.P)  ## == (L'P)' L'P == P'LL'P = XX = M M'
b <- sample(m)
stopifnot(all.equal(PLL, XX),
  all(as.vector(solve(CX, b, system="P")) == r$P %*% b),
  all(as.vector(solve(CX, b, system="Pt"))) == t(r$P) %*% b) )

u1 <- update(CX, XX, mult=pi)
u2 <- update(CX, t(M!), mult=pi)  # with the original M, where XX = M M'
stopifnot(all.equal(u1,u2, tol=1e-14))

## [ See help(Cholesky) for more examples ]
## --------------------------

### chol

**Choleski Decomposition - 'Matrix' S4 Generic and Methods**

**Description**

Compute the Choleski factorization of a real symmetric positive-definite square matrix.

**Usage**

```r
chol(x, ...)
```

## S4 method for signature 'dsCMatrix'

```r
chol(x, pivot = FALSE, ...)
```

## S4 method for signature 'dsparseMatrix'

```r
chol(x, pivot = FALSE, cache = TRUE, ...)
```

**Arguments**

- `x`  
a (sparse or dense) square matrix, here inheriting from class `Matrix`; if `x` is not positive definite, an error is signalled.

- `pivot`  
logical indicating if pivoting is to be used. Currently, this is not made use of for dense matrices.

- `cache`  
logical indicating if the result should be cached in `x@factors`; note that this argument is experimental and only available for some sparse matrices.

- `...`  
potentially further arguments passed to methods.

**Details**

Note that these Cholesky factorizations are typically cached with `x` currently, and these caches are available in `x@factors`, which may be useful for the sparse case when `pivot = TRUE`, where the permutation can be retrieved; see also the examples.

However, this should not be considered part of the API and made use of. Rather consider `Cholesky()` in such situations, since `chol(x, pivot=TRUE)` uses the same algorithm (but not the same return value!) as `Cholesky(x, LDL=FALSE)` and `chol(x)` corresponds to `Cholesky(x, perm=FALSE, LDL=FALSE).

**Value**

a matrix of class `Cholesky`, i.e., upper triangular: \( R \) such that \( R'R = x \) (if `pivot=FALSE`) or \( P'R'R'P = x \) (if `pivot=TRUE` and \( P \) is the corresponding permutation matrix).
Methods

Use `showMethods(chol)` to see all; some are worth mentioning here:

- **chol** signature(`x = "dgeMatrix"`): works via "dpoMatrix", see class `dpoMatrix`.
- **chol** signature(`x = "dpoMatrix"`): Returns (and stores) the Cholesky decomposition of `x`, via LAPACK routines `dlacpy` and `dpotrf`.
- **chol** signature(`x = "dppMatrix"`): Returns (and stores) the Cholesky decomposition via LAPACK routine `dpotrff`.
- **chol** signature(`x = "dsCMatrix", pivot = "logical"`): Returns (and stores) the Cholesky decomposition of `x`. If `pivot` is true, the Approximate Minimal Degree (AMD) algorithm is used to create a reordering of the rows and columns of `x` so as to reduce fill-in.

References

See Also

The default from `base`, `chol`; for more flexibility (but not returning a matrix!) *Cholesky*.

Examples

```r
showMethods(chol, inherited = FALSE) # show different methods

sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA, 32, 77))
(c2 <- chol(sy2)) #> "Cholesky" matrix
stopifnot(all.equal(c2, chol(as(sy2, "dpoMatrix")), tolerance= 1e-13))
str(c2)

## An example where chol() can't work
(sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7)))
try(chol(sy3)) # error, since it is not positive definite

## A sparse example --- exemplifying 'pivot'
(mm <- toeplitz(as(c(10, 0, 1, 0, 3), "sparseVector"))) # 5 x 5
(R <- chol(mm)) ## default: pivot = FALSE
R2 <- chol(mm, pivot=FALSE)
stopifnot( identical(R, R2), all.equal(crossprod(R), mm) )
(R. <- chol(mm, pivot=TRUE))# nice band structure,
## but of course crossprod(R.) is *NOT* equal to mm
## --> see Cholesky() and its examples, for the pivot structure & factorization
stopifnot(all.equal(sqrt(det(mm)), det(R)),
          all.equal(prod(diag(R)), det(R)),
          all.equal(prod(diag(R.)), det(R)))

## a second, even sparser example:
(M2 <- toeplitz(as(c(1,5, rep(0,12), -1), "sparseVector")))
c2 <- chol(M2)
C2 <- chol(M2, pivot=TRUE)
## For the experts, check the caching of the factorizations:
f <- M2@factors["spCholesky"]
```
Inverse from Choleski or QR Decomposition – Matrix Methods

Description

Invert a symmetric, positive definite square matrix from its Choleski decomposition. Equivalently, compute $(X'X)^{-1}$ from the $(R$ part) of the QR decomposition of $X$. Even more generally, given an upper triangular matrix $R$, compute $(R'R)^{-1}$.

Methods

- **x = "ANY"** the default method from `base`, see `chol2inv`, for traditional matrices.
- **x = "dtrMatrix"** method for the numeric triangular matrices, built on the same LAPACK DPOTRI function as the base method.
- **x = "denseMatrix"** if $x$ is coercable to a `triangularMatrix`, call the "dtrMatrix" method above.
- **x = "sparseMatrix"** if $x$ is coercable to a `triangularMatrix`, use `solve()` currently.

See Also

- `chol` (for Matrix objects); further, `chol2inv` (from the base package), `solve`.

Examples

```r
(M <- Matrix(cbind(1, 1:3, c(1,3,7))))
(cM <- chol(M)) # a "Cholesky" object, inheriting from "dtrMatrix"
chol2inv(cM) %*% M # the identity
stopifnot(all(chol2inv(cM) %*% M - Diagonal(nrow(M))) < 1e-10)
```

Cholesky Decomposition of a Sparse Matrix

Description

Computes the Cholesky (aka “Choleski”) decomposition of a sparse, symmetric, positive-definite matrix. However, typically `chol()` should rather be used unless you are interested in the different kinds of sparse Cholesky decompositions.

Usage

`Cholesky(A, perm = TRUE, LDL = !super, super = FALSE, Imult = 0, ...)`
Arguments

A  sparse symmetric matrix. No missing values or IEEE special values are allowed.
perm  logical scalar indicating if a fill-reducing permutation should be computed and applied to the rows and columns of A. Default is TRUE.
LDL  logical scalar indicating if the decomposition should be computed as LDL’ where L is a unit lower triangular matrix. The alternative is LL’ where L is lower triangular with arbitrary diagonal elements. Default is TRUE. Setting it to NA leaves the choice to a CHOLMOD-internal heuristic.
super  logical scalar indicating if a supernodal decomposition should be created. The alternative is a simplicial decomposition. Default is FALSE. Setting it to NA leaves the choice to a CHOLMOD-internal heuristic.
Imult  numeric scalar which defaults to zero. The matrix that is decomposed is $A + m \cdot I$ where $m$ is the value of Imult and I is the identity matrix of order ncol(A).
...  further arguments passed to or from other methods.

Details

This is a generic function with special methods for different types of matrices. Use showMethods("Cholesky") to list all the methods for the Cholesky generic.
The method for class dsCMatrix of sparse matrices — the only one available currently — is based on functions from the CHOLMOD library.
Again: If you just want the Cholesky decomposition of a matrix in a straightforward way, you should probably rather use chol(.)
Note that if perm=TRUE (default), the decomposition is

$$A = P' \tilde{L} \tilde{D} \tilde{P} = P'LL'P,$$

where $L$ can be extracted by as(*, "Matrix"), $P$ by as(*, "pMatrix") and both by expand(*), see the class CHMfactor documentation.
Note that consequently, you cannot easily get the “traditional” cholesky factor $R$, from this decomposition, as

$$R'R = A = P'LL'P = P'\tilde{R}'\tilde{R}P = (\tilde{R}P)'(\tilde{R}P),$$

but $\tilde{R}P$ is not triangular even though $\tilde{R}$ is.

Value

an object inheriting from either "CHMsuper", or "CHMsimpl", depending on the super argument; both classes extend "MatrixFactorization".
In other words, the result of Cholesky() is not a matrix, and if you want one, you should probably rather use chol(), see Details.

References

See Also

Class definitions \texttt{CHMfactor} and \texttt{dsCMatrix} and function \texttt{expand}. Note the extra \texttt{solve(\*, system = .)} options in \texttt{CHMfactor}.

Note that \texttt{chol()} returns matrices (inheriting from "Matrix") whereas \texttt{Cholesky()} returns a "\texttt{CHMfactor}" object, and hence a typical user will rather use \texttt{chol(A)}.

Examples

```r
data(KNex)
mtm <- with(KNex, crossprod(mm))
str(mtM@factors) # empty list()
(C1 <- Cholesky(mtm)) # uses show(<MatrixFactorization>)
str(mtM@factors) # 'sPDCholesky' (simply)
(Cm <- Cholesky(mtm, super = TRUE))
c(C1 = isLDL(C1), Cm = isLDL(Cm))
str(mtM@factors) # 'sPDCholesky' *and* 'SPDCholesky'
str(cm1 <- as(C1, "sparseMatrix"))
str(cmat <- as(Cm, "sparseMatrix")) # hmm: super is *less* sparse here

b <- matrix(c(rep(0, 711), 1), nc = 1)
## solve(Cm, b) by default solves A x = b, where A = Cm'Cm (= mtm)!
## hence, the identical() check *should* work, but fails on some GOTOblas:
x <- solve(Cm, b)
stopifnot(identical(x, solve(Cm, b, system = "A")),
          all.equal(x, solve(mtm, b)))

Cn <- Cholesky(mtm, perm = FALSE)# no permutation -- much worse:
sizes <- c(simple = object.size(C1),
          super = object.size(Cm),
          noPerm = object.size(Cn))
## simple is 100, super= 137, noPerm= 812 :
noquote( cbind( format(100 * sizes / sizes[1], digits=4) )))

## Visualize the sparseness:
dq <- function(ch) paste("", ch,"", sep="")  ## dQuote(<UTF-8>) gives bad plots
image(mtm, main=paste("crossprod(mm) : Sparse", dq(class(mtm))))
image(cm1, main= paste("as(Cholesky(crossprod(mm)),"sparseMatrix")::",
                      dq(class(cm1))))

## Smaller example, with same matrix as in help(chol) :
(dM <- Matrix(toeplitz(c(10, 0, 1, 0, 3)), sparse = TRUE)) # 5 x 5
(opts <- expand.grid(perm = c(TRUE,FALSE), LDL = c(TRUE,FALSE), super = c(FALSE,TRUE)))
rr <- lapply(seq_len(nrow(opts)), function(i)
              do.call(Cholesky, c(list(A = mm), opts[i,])))
nn <- do.call(expand.grid, c(attr(opts, "out.attr"),dimnames,
                      stringsAsFactors=FALSE,KEEP.OUT.ATTRS=FALSE))
names(rr) <- apply(nn, 1, function(r)
              paste(sub("=.\n", "\n", r), collapse=""))
str(rr, max=1)

str(re <- lapply(rr, expand), max=2)
## each has a 'P' and a 'L' matrix \texttt{FIXME}!! --- "check" them \_\_\_unfinished\_\_
R0 <- chol(mm, pivot=FALSE)
```
R1 <- chol(mm, pivot=TRUE)
stopifnot(all.equal(t(R1), re[[1]]$L),
  all.equal(t(RO), re[[2]]$L),
  identical(as(1:5, "pMatrix"), re[[2]]$P), # no pivoting
TRUE)

# Version of the underlying SuiteSparse library by Tim Davis:
.SuiteSparse_version()

Cholesky-class  

| Cholesky and Bunch-Kaufman Decompositions |

Description

The "Cholesky" class is the class of Cholesky decompositions of positive-semidefinite, real dense matrices. The "BunchKaufman" class is the class of Bunch-Kaufman decompositions of symmetric, real matrices. The "pCholesky" and "pBunchKaufman" classes are their packed storage versions.

Objects from the Class

Objects can be created by calls of the form new("Cholesky", ...) or new("BunchKaufman", ...), etc. or rather by calls of the form chol(pm) or BunchKaufman(pm) where pm inherits from the "dpoMatrix" or "dsyMatrix" class or as a side-effect of other functions applied to "dpoMatrix" objects (see dpoMatrix).

Slots

A Cholesky decomposition extends class MatrixFactorization but is basically a triangular matrix extending the "dtrMatrix" class.

uplo: inherited from the "dtrMatrix" class.
diag: inherited from the "dtrMatrix" class.
x: inherited from the "dtrMatrix" class.
dim: inherited from the "dtrMatrix" class.
dimnames: inherited from the "dtrMatrix" class.

A Bunch-Kaufman decomposition also extends the "dtrMatrix" class and has a perm slot representing a permutation matrix. The packed versions extend the "dtpMatrix" class.

Extends

Class "MatrixFactorization" and "dtrMatrix", directly. Class "dgeMatrix", by class "dtrMatrix". Class "Matrix", by class "dtrMatrix".

Methods

Both these factorizations can directly be treated as (triangular) matrices, as they extend "dtrMatrix", see above. There are currently no further explicit methods defined with class "Cholesky" or "BunchKaufman" in the signature.
Note

1. Objects of class "Cholesky" typically stem from \texttt{chol(D)}, applied to a \textit{dense} matrix D. On the other hand, the \texttt{function Cholesky(S)} applies to a \textit{sparse} matrix S, and results in objects inheriting from class \texttt{CHMfactor}.

2. For traditional matrices \texttt{m}, \texttt{chol(m)} is a traditional matrix as well, triangular, but simply an \( n \times n \) numeric \texttt{matrix}. Hence, for compatibility, the "Cholesky" and "BunchKaufman" classes (and their "p*" packed versions) also extend triangular Matrix classes (such as "dtrMatrix"). Consequently, \texttt{determinant(r) \leftarrow chol(A)} returns the determinant of \( R \), not of \( A \). This is in contrast to class \texttt{CHMfactor} objects \( C \), where \texttt{determinant(C)} gives the determinant of the \textit{original} matrix \( A \), for \( C \leftarrow \text{Cholesky}(A) \), see also the determinant method documentation on the class \texttt{CHMfactor} page.

See Also

Classes \texttt{dtrMatrix, dpoMatrix}; function \texttt{chol}.

Function \texttt{Cholesky} resulting in class \texttt{CHMfactor} objects, \textit{not} class "Cholesky" ones, see the section 'Note'.

Examples

\begin{verbatim}
(sm <- as(as(Matrix(diag(5) + 1), "dsyMatrix"), "dspMatrix"))
signif(csm <- chol(sm), 4)

(pm <- crossprod(Matrix(rnorm(18), nrow = 6, ncol = 3)))
(ch <- chol(pm))
if (toupper(ch@uplo) == "U") # which is TRUE
crossprod(ch)
stopifnot(all.equal(as(crossprod(ch), "matrix"),
    as(pm, "matrix"), tolerance=1e-14))
\end{verbatim}

\begin{Verbatim}
colSums  \hspace{1cm} \textit{Form Row and Column Sums and Means}
\end{Verbatim}

Description

Form row and column sums and means for \texttt{Matrix} objects.

Usage

\begin{verbatim}
colSums (x, na.rm = FALSE, dims = 1, ...)
rowSums (x, na.rm = FALSE, dims = 1, ...)
colMeans(x, na.rm = FALSE, dims = 1, ...)
rowMeans(x, na.rm = FALSE, dims = 1, ...)
\end{verbatim}

\begin{verbatim}
## S4 method for signature 'CsparseMatrix'
colSums(x, na.rm = FALSE, dims = 1, sparseResult = FALSE)
## S4 method for signature 'CsparseMatrix'
rowSums(x, na.rm = FALSE, dims = 1, sparseResult = FALSE)
## S4 method for signature 'CsparseMatrix'
\end{verbatim}
Arguments

- **x**: a Matrix, i.e., inheriting from *Matrix*.
- **na.rm**: logical. Should missing values (including NaN) be omitted from the calculations?
- **dims**: completely ignored by the *Matrix* methods.
- **...**: potentially further arguments, for method <-> generic compatibility.
- **sparseResult**: logical indicating if the result should be sparse, i.e., inheriting from class *sparseVector*.

Value

returns a numeric vector if sparseResult is FALSE as per default. Otherwise, returns a *sparseVector*.

See Also

*colSums* and the *sparseVector* classes.

Examples

```r
(M <- bdiag(Diagonal(2), matrix(1:3, 3, 4), diag(3:2))) # 7 x 8
colSums(M)
d <- Diagonal(10, c(0,0,10,0,2,rep(0,5)))
MM <- kronecker(d, M)
dim(MM) # 70 80
length(MM@x) # 160, but many are '0' ; drop those:
MM <- drop0(MM)
length(MM@x) # 32

(cm <- colSums(MM))
stopifnot(is(cm, "sparseVector"),
          identical(cm, as.numeric(cm)))
rowSums (MM, sparseResult = TRUE) # 14 of 70 are not zero
colMeans(MM, sparseResult = TRUE) # 16 of 80 are not zero
## Since we have no 'NA' s, these two are equivalent :
stopifnot(identical(rowMeans(MM, sparseResult = TRUE),
                    rowMeans(MM, sparseResult = TRUE, na.rm = TRUE)),
          rowMeans(Diagonal(16)) == 1/16,
          colSums(Diagonal(7)) == 1)
```
compMatrix-class  

Class "compMatrix" of Composite (Factorizable) Matrices

Description

Virtual class of composite matrices; i.e., matrices that can be factorized, typically as a product of simpler matrices.

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

factors: Object of class "list" - a list of factorizations of the matrix. Note that this is typically empty, i.e. list(), initially and is updated automagically whenever a matrix factorization is computed.

dim, Dimnames: inherited from the Matrix class, see there.

Extends

Class "Matrix", directly.

condest

Compute Approximate CONDITION number and 1-Norm of (Large) Matrices

Description

"Estimate", i.e. compute approximately the CONDITION number of a (potentially large, often sparse) matrix A. It works by apply a fast randomized approximation of the 1-norm, norm(A,"1"), through onenormest().

Usage

condest(A, t = min(n, 5), normA = norm(A, "1"), silent = FALSE, quiet = TRUE)

onenormest(A, t = min(n, 5), A.x, At.x, n, silent = FALSE, quiet = silent, iter.max = 10, eps = 4 * .Machine$double.eps)
Arguments

- **A** 
  a square matrix, optional for onenormest(), where instead of `A, A.x` and `At.x` can be specified, see there.

- **t** 
  number of columns to use in the iterations.

- **normA** 
  number; (an estimate of) the 1-norm of `A`, by default `norm(A, "1")`; may be replaced by an estimate.

- **silent** 
  logical indicating if warning and (by default) convergence messages should be displayed.

- **quiet** 
  logical indicating if convergence messages should be displayed.

- **A.x, At.x** 
  when `A` is missing, these two must be given as functions which compute `A \times x`, or `t(A) \times x`, respectively.

- **n** 
  `nrow(A)`, only needed when `A` is not specified.

- **iter.max** 
  maximal number of iterations for the 1-norm estimator.

- **eps** 
  the relative change that is deemed irrelevant.

Details

`condest()` calls `lu(A)`, and subsequently `onenormest(A.x = , At.x = )` to compute an approximate norm of the inverse of `A, A^{-1}`, in a way which keeps using sparse matrices efficiently when `A` is sparse.

Note that `onenormest()` uses random vectors and hence both functions' results are random, i.e., depend on the random seed, see, e.g., `set.seed()`.

Value

Both functions return a list; `condest()` with components,

- **est** 
  a number > 0, the estimated (1-norm) condition number $\hat{\kappa}$; when $r := \text{cond}(A), 1/\hat{\kappa} \approx r$.

- **v** 
  the maximal $Ax$ column, scaled to $\text{norm}(v) = 1$. Consequently, $\text{norm}(Av) = \text{norm}(A)/\text{est}$; when est is large, $v$ is an approximate null vector.

The function `onenormest()` returns a list with components,

- **est** 
  a number > 0, the estimated $\text{norm}(A, "1")$.

- **v** 
  0-1 integer vector length `n`, with an 1 at the index `j` with maximal column $A[i, j]$ in `A`.

- **w** 
  numeric vector, the largest $Ax$ found.

- **iter** 
  the number of iterations used.

Author(s)

This is based on octave’s `condest()` and `onenormest()` implementations with original author Jason Riedy, U Berkeley; translation to R and adaption by Martin Maechler.

References

See Also

Examples

data(KNex)
mtm <- with(KNex, crossprod(mm))
system.time(ce <- condest(mtm))
sum(abs(ce$v))  ## |v||A|| = |A||/est
system.time(ce <- condest(mtm))  ## |v||A|| = |A||/est
system.time(ce <- condest(mtm))  ## |v||A|| = |A||/est
system.time(ce <- condest(mtm))  ## |v||A|| = |A||/est
system.time(rcond(mtm))  # takes ca 3 x longer
rcond(mtm)  # TRUE -- the approximation was good
one <- onenormest(mtm)
str(one)  ## est = 12.3
str(one)  ## est = 12.3
# the maximal column:
which(one$v == 1)  # mostly 4, rarely 1, depending on random seed

CsparseMatrix-class  Class "CsparseMatrix" of Sparse Matrices in Column-compressed Form

Description

The "CsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed column-oriented form. Since it is a virtual class, no objects may be created from it. See showClass("CsparseMatrix") for its subclasses.

Slots

i: Object of class "integer" of length nnzero (number of non-zero elements). These are the zero-based row numbers for each non-zero element in the matrix, i.e., i must be in \(0: (\text{rown}()-1)\).

p: integer vector for providing pointers, one for each column, to the initial (zero-based) index of elements in the column. \(p\) is of length \(\text{ncol}(m) + 1\), with \(p[1] = 0\) and \(p[\text{length}(p)] = \text{nnzero}\), such that in fact, \(\text{diff}(\cdot p)\) are the number of non-zero elements for each column.

In other words, \(m[p[1]:\text{ncol}(m)]\) contains the indices of those elements in \(m\) that are the first elements in the respective column of \(m\).

Dim, Dimnames: inherited from the superclass, see the sparseMatrix class.

Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".
CsparseMatrix-class

Methods

matrix products `%*%`, `crossprod()` and `tcrossprod()`, several `solve` methods, and other matrix methods available:

gamma signature(x = "CsparseMatrix"): ...

t signature(x = "CsparseMatrix"): ...

triu signature(x = "CsparseMatrix"): ...

Note

All classes extending CsparseMatrix have a common validity (see `validObject`) check function. That function additionally checks the i slot for each column to contain increasing row numbers. In earlier versions of Matrix (< 0.999375-16), `validObject` automatically re-sorted the entries when necessary, and hence `new()` calls with somewhat permuted i and x slots worked, as `new(...)` (with slot arguments) automatically checks the validity.

Now, you have to use `sparseMatrix` to achieve the same functionality or know how to use `.validateCsparse()` to do so.

## The common validity check function (based on C code):
getValidity(getClass("CsparseMatrix"))
**ddenseMatrix-class**

*Virtual Class "ddenseMatrix" of Numeric Dense Matrices*

**Description**

This is the virtual class of all dense numeric (i.e., double, hence “ddense”) S4 matrices. Its most important subclass is the **dgeMatrix** class.

**Extends**

Class "dMatrix" directly; class "Matrix", by the above.

**Slots**

the same slots at its subclass **dgeMatrix**, see there.

**Methods**

Most methods are implemented via `as(*, "dgeMatrix")` and are mainly used as “fallbacks” when the subclass doesn’t need its own specialized method.

Use `showMethods(class = "ddenseMatrix", where = "package:Matrix")` for an overview.

**See Also**

The virtual classes **Matrix**, **dMatrix**, and **dsparseMatrix**.

**Examples**

```
showClass("ddenseMatrix")
showMethods(class = "ddenseMatrix", where = "package:Matrix")
```

---

**ddiMatrix-class**

*Class “ddiMatrix” of Diagonal Numeric Matrices*

**Description**

The class “ddiMatrix” of numerical diagonal matrices.

Note that diagonal matrices now extend **sparseMatrix**, whereas they did extend dense matrices earlier.

**Objects from the Class**

Objects can be created by calls of the form `new("ddiMatrix", ...)` but typically rather via **Diagonal**.
denseMatrix-class

Slots

x: numeric vector. For an \( n \times n \) matrix, the \( x \) slot is of length \( n \) or 0, depending on the diag slot:
diag: "character" string, either "U" or "N" where "U" denotes unit-diagonal, i.e., identity matrices.

Dim, Dimnames: matrix dimension and dimnames, see the Matrix class description.

Extends

Class "diagonalMatrix", directly. Class "dMatrix", directly. Class "sparseMatrix", indirectly, see showClass("ddiMatrix").

Methods

\%*\% signature(x = "ddiMatrix", y = "ddiMatrix"): ...

See Also

Class diagonalMatrix and function Diagonal.

Examples

(d2 <- Diagonal(x = c(10,1)))
str(d2)
## slightly larger in internal size:
str(as(d2, "sparseMatrix"))

M <- Matrix(cbind(1,2:4))
M \%*\% d2 \# 'fast' multiplication

chol(d2) \# trivial
stopifnot(is(cd2 <- chol(d2), "ddiMatrix"),
all.equal(cd2@x, c(sqrt(10),1)))

---

denseMatrix-class  Virtual Class "denseMatrix" of All Dense Matrices

Description

This is the virtual class of all dense (S4) matrices. It is the direct superclass of ddenseMatrix, ldenseMatrix

Extends

class "Matrix" directly.

Slots

exactly those of its superclass "Matrix".
Methods

Use `showMethods(class = "denseMatrix", where = "package:Matrix")` for an overview of methods.

Extraction ("[" methods, see `[methods`.

dgCMatric-class | Compressed, sparse, column-oriented numeric matrices

Description

The `dgCMatrix` class is a class of sparse numeric matrices in the compressed, sparse, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order. `dgCMatrix` is the "standard" class for sparse numeric matrices in the `Matrix` package.

Objects from the Class

Objects can be created by calls of the form `new("dgCMatrix", ...), more typically via as(*, "CsparseMatrix")` or similar. Often however, more easily via `Matrix(*, sparse = TRUE), or most efficiently via sparseMatrix()`.

Slots

`x`: Object of class "numeric" - the non-zero elements of the matrix.

... all other slots are inherited from the superclass "CsparseMatrix".

Methods

Matrix products (e.g., crossprod-methods), and (among other)

`coerce` signature(from = "matrix", to = "dgCMatrix")

`coerce` signature(from = "dgCMatrix", to = "matrix")

`coerce` signature(from = "dgCMatrix", to = "dgTMatrix")

diag signature(x = "dgCMatrix"): returns the diagonal of x

dim signature(x = "dgCMatrix"): returns the dimensions of x

image signature(x = "dgCMatrix"): plots an image of x using the levelplot function

solve signature(a = "dgCMatrix", b = "..."): see solve-methods, notably the extra argument sparse.

lu signature(x = "dgCMatrix"): computes the LU decomposition of a square dgCMatrix object
A general numeric dense matrix in the S4 Matrix representation. `dgeMatrix` is the "standard" class for dense numeric matrices in the `Matrix` package.

Objects from the Class

Objects can be created by calls of the form `new("dgeMatrix", ...)` or, more commonly, by coercion from the `matrix` class (see `Matrix`) or by `Matrix(.)`.

Slots

- `x`: Object of class "numeric" - the numeric values contained in the matrix, in column-major order.
- `Dim`: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.
- `Dimnames`: a list of length two - inherited from class `matrix`.
- `factors`: Object of class "list" - a list of factorizations of the matrix.

Methods

The are group methods (see, e.g., `Arith`)

- `Arith` signature(e1 = "dgeMatrix", e2 = "dgeMatrix"): ...
- `Arith` signature(e1 = "dgeMatrix", e2 = "numeric"): ...
- `Arith` signature(e1 = "numeric", e2 = "dgeMatrix"): ...
- `Math` signature(x = "dgeMatrix"): ...
- `Math2` signature(x = "dgeMatrix", digits = "numeric"): ...

matrix products `%*%`, `crossprod()` and `tcrossprod()`, several `solve` methods, and other matrix methods available:

- `Schur` signature(x = "dgeMatrix", vectors = "logical"): ...
- `Schur` signature(x = "dgeMatrix", vectors = "missing"): ...
- `chol` signature(x = "dgeMatrix"): see `chol`.
- `coerce` signature(from = "dgeMatrix", to = "lgeMatrix"): ...
- `coerce` signature(from = "dgeMatrix", to = "matrix"): ...
coerce signature(from = "matrix", to = "dgeMatrix"): ...

colMeans signature(x = "dgeMatrix"): columnwise means (averages)

colSums signature(x = "dgeMatrix"): columnwise sums

diag signature(x = "dgeMatrix"): ...
dim signature(x = "dgeMatrix"): ...
dimnames signature(x = "dgeMatrix"): ...
eigen signature(x = "dgeMatrix", only.values = "logical"): ...
eigen signature(x = "dgeMatrix", only.values = "missing"): ...
norm signature(x = "dgeMatrix", type = "character"): ...
norm signature(x = "dgeMatrix", type = "missing"): ...
rcond signature(x = "dgeMatrix", norm = "character") or norm = "missing": the reciprocal condition number: rcond().

rowMeans signature(x = "dgeMatrix"): rowwise means (averages)

rowSums signature(x = "dgeMatrix"): rowwise sums
t signature(x = "dgeMatrix"): matrix transpose

See Also

Classes Matrix, dtrMatrix, and dsyMatrix.

dgRMatrix-class

Sparse Compressed, Row-oriented Numeric Matrices

Description

The dgRMatrix class is a class of sparse numeric matrices in the compressed, sparse, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

Note: The column-oriented sparse classes, e.g., dgCMatrix, are preferred and better supported in the Matrix package.

Objects from the Class

Objects can be created by calls of the form new("dgRMatrix", ...).

Slots

j: Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each non-zero element in the matrix.
p: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.
x: Object of class "numeric" - the non-zero elements of the matrix.
Dim: Object of class "integer" - the dimensions of the matrix.
**Methods**

`coerce` signature(from = "matrix", to = "dgRMatrix")
`coerce` signature(from = "dgRMatrix", to = "matrix")
`coerce` signature(from = "dgRMatrix", to = "dgTMatrix")
`diag` signature(x = "dgRMatrix"): returns the diagonal of x
`dim` signature(x = "dgRMatrix"): returns the dimensions of x
`image` signature(x = "dgRMatrix"): plots an image of x using the `levelplot` function

**See Also**

the `RsparseMatrix` class, the virtual class of all sparse compressed row-oriented matrices, with its methods. The `dgCMatrix` class (column compressed sparse) is really preferred.

---

**Description**

The "dgTMatrix" class is the class of sparse matrices stored as (possibly redundant) triplets. The internal representation is not at all unique, contrary to the one for class `dgCMatrix`.

**Objects from the Class**

Objects can be created by calls of the form `new("dgTMatrix", ...)`, but more typically via `as(*, "dgTMatrix"), spMatrix()`, or `sparseMatrix(*, giveCsparse=FALSE)`.

**Slots**

- `i`: Object of class "integer" - the row indices of non-zero entries in 0-base, i.e., must be in `0:(nrow(.)-1)`.
- `j`: Object of class "integer" - the column indices of non-zero entries. Must be the same length as slot `i` and 0-based as well, i.e., in `0:(ncol(.)-1)`.
- `x`: Object of class "numeric" - the (non-zero) entry at position `(i,j)`. Must be the same length as slot `i`. If an index pair occurs more than once the corresponding values of slot `x` are added to form the element of the matrix.
- `Dim`: Object of class "integer" of length 2 - the dimensions of the matrix.

**Methods**

`+` signature(e1 = "dgTMatrix", e2 = "dgTMatrix")
`coerce` signature(from = "dgTMatrix", to = "dgCMatrix")
`coerce` signature(from = "dgTMatrix", to = "dgeMatrix")
`coerce` signature(from = "dgTMatrix", to = "matrix"), and typically coercion methods for more specific signatures, we are not mentioning here.

Note that these are not guaranteed to continue to exist, but rather you should use calls like `as(x,"CsparseMatrix"), as(x, "generalMatrix"), as(x, "dMatrix"), i.e. coercion to higher level virtual classes.
coerce signature(from = "matrix", to = "dgTMatrix"), (direct coercion from tradition matrix).

image signature(x = "dgTMatrix"): plots an image of x using the levelplot function

t signature(x = "dgTMatrix"): returns the transpose of x

Note

Triplet matrices are a convenient form in which to construct sparse matrices after which they can be coerced to dgCMatrix objects.

Note that both new(.) and spMatrix constructors for "dgTMatrix" (and other "linkS4class(TsparseMatrix)" classes) implicitly add \( x_k \)'s that belong to identical \( (i_k, j_k) \) pairs.

See Also

Class dgCMatrix or the superclasses dsparseMatrix and TsparseMatrix;

Examples

m <- Matrix(0+1:28, nrow = 4)
m[-3, c(2,4:5,7)] <- m[3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "dgTMatrix"))
str(mT)
mT[1,]
mT[4, drop = FALSE]
stopifnot(identical(mT[lower.tri(mT),
    m [lower.tri(m) ]]),
    mT[lower.tri(mT, diag=TRUE)] <- 0
    mT

## Triplet representation with repeated (i,j) entries
## *adds* the corresponding x's:
T2 <- new("dgTMatrix",
    i = as.integer(c(1,1,0,3,3)),
    j = as.integer(c(2,2,4,0,0)),
    x=10*1:5, Dim=4:5)
str(T2) # contains (i,j,x) slots exactly as above, but
T2 ## has only three non-zero entries, as for repeated (i,j)'s,
    ## the corresponding x's are "implicitly" added
stopifnot(nnzero(T2) == 3)
Usage

Diagonal(n, x = NULL)

.symDiagonal(n, x = rep.int(1,n), uplo = "U")
.sparseDiagonal(n, x = 1, uplo = "U",
shape = if(missing(cols)) "t" else "g",
unitri, kind, cols = if(n) 0:(n - 1L) else integer(0))

Arguments

n integer specifying the dimension of the (square) matrix. If missing, length(x) is used.
x numeric or logical; if missing, a unit diagonal n × n matrix is created.
uplo for .symDiagonal, the resulting sparse symmetricMatrix will have slot uplo set from this argument, either "U" or "L". Only rarely will it make sense to change this from the default.
shape string of 1 character, one of "t", "s", "g"), to choose a triangular, symmetric or general result matrix.
unitri optional logical indicating if a triangular result should be “unit-triangular”, i.e., with diag = "U" slot, if possible. The default, missing, is the same as TRUE.
kind string of 1 character, one of c("d","l","n"), to choose the storage mode of the result, from classes dsparseMatrix, lsparseMatrix, or nsparseMatrix, respectively.
cols integer vector with values from 0:(n-1), denoting the columns to subselect conceptually, i.e., get the equivalent of Diagonal(n,)[, cols + 1].

Value

Diagonal() returns an object of class ddiMatrix or ldiMatrix (with “superclass” diagonalMatrix).
.symDiagonal() returns an object of class dsCMatrix or lsCMatrix, i.e., a sparse symmetric matrix. This can be more efficient than Diagonal(n) when the result is combined with further symmetric (sparse) matrices, however not for matrix multiplications where Diagonal() is clearly preferred.
.sparseDiagonal(), the workhorse of .symDiagonal returns a CsparseMatrix (the resulting class depending on shape and kind) representation of Diagonal(n), or, when cols are specified, of Diagonal(n)[, cols+1].

Author(s)

Martin Maechler

See Also

the generic function diag for extraction of the diagonal from a matrix works for all “Matrices”. bandSparse constructs a banded sparse matrix from its non-zero sub-/super - diagonals. band(A) returns a band matrix containing some sub-/super - diagonals of A. Matrix for general matrix construction; further, class diagonalMatrix.
Examples

Diagonal(3)
Diagonal(x = 10^c(3:1))
Diagonal(x = (1:4) >= 2) -> "ldiMatrix"

## Use Diagonal() + kronecker() for "repeated-block" matrices:
M1 <- Matrix(0+0:5, 2,3)
(M <- kronecker(Diagonal(3), M1))

(S <- crossprod(Matrix(rbinom(60, size=1, prob=0.1), 10,6)))
(SI <- S + 10*symDiagonal(6)) # sparse symmetric still
stopifnot(is(SI, "dsCMatrix"))
(I4 <- .sparseDiagonal(4, shape="t"))# now (2012-10) unitriangular
stopifnot(I4@diag == "U", all(I4 == diag(4)))

diagonalMatrix-class  Class "diagonalMatrix" of Diagonal Matrices

Description

Class "diagonalMatrix" is the virtual class of all diagonal matrices.

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

diag:  code"character" string, either "U" or "N", where "U" means 'unit-diagonal'.
Dim:  matrix dimension, and
Dimnames: the dimnames, a list, see the Matrix class description. Typically list(NULL,NULL) for diagonal matrices.

Extends

Class "sparseMatrix", directly.

Methods

These are just a subset of the signature for which defined methods. Currently, there are (too) many explicit methods defined in order to ensure efficient methods for diagonal matrices.

coerce signature(from = "matrix", to = "diagonalMatrix"): ...
coerce signature(from = "Matrix", to = "diagonalMatrix"): ...
coerce signature(from = "diagonalMatrix", to = "generalMatrix"): ...
coerce signature(from = "diagonalMatrix", to = "triangularMatrix"): ...
coerce signature(from = "diagonalMatrix", to = "nMatrix"): ...
coerce signature(from = "diagonalMatrix", to = "matrix"): ...
coerce signature(from = "diagonalMatrix", to = "sparseVector"): ...
Transform Triangular Matrices from Unit Triangular to General and back

Transform a triangular matrix x, i.e., of class "triangularMatrix", from (internally!) unit triangular ("unitriangular") to "general" (diagU2N(x)) or back (diagN2U(x)). Note that the latter, diagN2U(x), also sets the diagonal to one in cases where diag(x) was not all one.

.diagU2N(x) assumes but does not check that x is a triangularMatrix with diag slot "U", and should hence be used with care.
Usage

diagN2U(x, cl = getClassDef(class(x)), checkDense = FALSE)
diagU2N(x, cl = getClassDef(class(x)), checkDense = FALSE)
.diagU2N(x, cl, checkDense = FALSE)

Arguments

x  
a triangularMatrix, often sparse.
cl  
(optional, for speedup only:) class (definition) of x.
checkDense  
logical indicating if dense (see denseMatrix) matrices should be considered at all; i.e., when false, as per default, the result will be sparse even when x is dense.

Details

The concept of unit triangular matrices with a diag slot of "U" stems from LAPACK.

Value

a triangular matrix of the same class and (semantically) with identical entries as x, but with a different diag slot.

Note

Such internal storage details should rarely be of relevance to the user. Hence, these functions really are rather internal utilities.

See Also

"triangularMatrix", "dtCMatrix".

Examples

(T <- Diagonal(7) + triu(Matrix(rpois(49, 1/4), 7,7), k = 1))
(uT <- diagN2U(T)) # "unitriangular"
(t.u <- diagN2U(10*T))# changes the diagonal!
stopifnot(all(T == uT), diag(t.u) == 1,
identical(T, diagU2N(uT)))
T[upper.tri(T)] <- 5
T <- diagN2U(as(T,"triangularMatrix"))
stopifnot(T@diag == "U")
dT <- as(T, "denseMatrix")
dt. <- diagN2U(dt)
dtU <- diagN2U(dt, checkDense=TRUE)
stopifnot(is(dtU, "denseMatrix"), is(dt., "sparseMatrix"),
all(dt == dt.), all(dt == dtU),
dt.@diag == "U", dtU@diag == "U")
dMatrix-class

(Virtual) Class "dMatrix" of "double" Matrices

Description
The dMatrix class is a virtual class contained by all actual classes of numeric matrices in the Matrix package. Similarly, all the actual classes of logical matrices inherit from the lMatrix class.

Slots
Common to all matrix object in the package:

Dim: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

Dimnames: list of length two; each component containing NULL or a character vector length equal the corresponding Dim element.

Methods
There are (relatively simple) group methods (see, e.g., Arith)

Arith signature(e1 = "dMatrix", e2 = "dMatrix"): ...
Arith signature(e1 = "dMatrix", e2 = "numeric"): ...
Arith signature(e1 = "numeric", e2 = "dMatrix"): ...
Math signature(x = "dMatrix"): ...
Math2 signature(x = "dMatrix", digits = "numeric"): this group contains round() and signif().
Compare signature(e1 = "numeric", e2 = "dMatrix"): ...
Compare signature(e1 = "dMatrix", e2 = "numeric"): ...
Compare signature(e1 = "dMatrix", e2 = "dMatrix"): ...
Summary signature(x = "dMatrix"): The "Summary" group contains the seven functions max(), min(), range(), prod(), sum(), any(), and all().

The following methods are also defined for all double matrices:

coerce signature(from = "dMatrix", to = "matrix"): ...
expm signature(x = "dMatrix"): computes the “Matrix Exponential”, see expm.
zapsmall signature(x = "dMatrix"): ...

The following methods are defined for all logical matrices:

which signature(x = "lsparseMatrix") and many other subclasses of "lMatrix": as the base function which(x, arr.ind) returns the indices of the TRUE entries in x; if arr.ind is true, as a 2-column matrix of row and column indices.

See Also
The nonzero-pattern matrix class nMatrix, which can be used to store non-NA logical matrices even more compactly.
The numeric matrix classes dgeMatrix, dgCMatrix, and Matrix.
drop0(x, tol=1e-10) is sometimes preferable to (and more efficient than) zapsmall(x, digits=10).
Examples

```r
showClass("dMatrix")

set.seed(101)
round(Matrix(rnorm(28), 4, 7), 2)
M <- Matrix(rlnorm(56, sd=10), 4, 14)
(M. <- zapsmall(M))
table(as.logical(M. == 0))
```

**dpoMatrix-class**  Positive Semi-definite Dense Numeric Matrices

**Description**

The "dpoMatrix" class is the class of positive-semidefinite symmetric matrices in nonpacked storage. The "dpMMatrix" class is the same except in packed storage. Only the upper triangle or the lower triangle is required to be available.

The "corMatrix" class extends "dpoMatrix" with a slot `sd`.

**Objects from the Class**

Objects can be created by calls of the form `new("dpoMatrix", ...)` or from `crossprod` applied to an "dgeMatrix" object.

**Slots**

- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- `x`: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.
- `Dim`: Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.
- `Dimnames`: inherited from class "Matrix"
- `factors`: Object of class "list". A named list of factorizations that have been computed for the matrix.
- `sd`: (for "corMatrix") a numeric vector of length n containing the (original) \(\sqrt{\text{var}(.)}\) entries which allow reconstruction of a covariance matrix from the correlation matrix.

**Extends**

Class "dsyMatrix", directly.
Classes "dgeMatrix", "symmetricMatrix", and many more by class "dsyMatrix".

**Methods**

- `chol` signature(x = "dpoMatrix"): Returns (and stores) the Cholesky decomposition of x, see `chol`.
- `determinant` signature(x = "dpoMatrix"): Returns the determinant of x, via `chol(x)`, see above.
rcond signature(x = "dpoMatrix", norm = "character"): Returns (and stores) the reciprocal of the condition number of x. The norm can be "0" for the one-norm (the default) or "I" for the infinity-norm. For symmetric matrices the result does not depend on the norm.

solve signature(a = "dpoMatrix", b = "...."). and

solve signature(a = "dppMatrix", b = "....") work via the Cholesky composition, see also the Matrix solve-methods.

Arith signature(e1 = "dpoMatrix", e2 = "numeric") (and quite a few other signatures): The result of ("elementwise" defined) arithmetic operations is typically not positive-definite any more. The only exceptions, currently, are multiplications, divisions or additions with positive length(.), == 1 numbers (or logicals).

See Also

Classes dsysMatrix and dgeMatrix; further, Matrix, rcond, chol, solve, crossprod.

Examples

h6 <- Hilbert(6)
rm6(h6)
str(h6)
h6 * 27720 # is \``integer\''
solve(h6)
str(hp6 <- as(h6, "dppMatrix"))

### Note that as(*, "corMatrix") *scales* the matrix
(ch6 <- as(h6, "corMatrix"))
stopifnot(all.equal(h6 * 27720, round(27720 * h6), tolerance = 1e-14),
  all.equal(ch6@sd*(-2), 2*(1:6)-1, tolerance= 1e-12))
chch <- chol(ch6)
stopifnot(identical(chch, ch6@factors@Cholesky),
  all(abs(crossprod(chch) - ch6) < 1e-10))

---

**drop0**

*Drop "Explicit Zeroes" from a Sparse Matrix*

**Description**

Returns a sparse matrix with no "explicit zeroes", i.e., all zero or FALSE entries are dropped from the explicitly indexed matrix entries.

**Usage**

`drop0(x, tol = 0, is.Csparse = NA)`

**Arguments**

- **x**
  - a Matrix, typically sparse, i.e., inheriting from `sparseMatrix`.

- **tol**
  - non-negative number to be used as tolerance for checking if an entry $x_{i,j}$ should be considered to be zero.

- **is.Csparse**
  - logical indicating prior knowledge about the “Csparseeness” of x. This exists for possible speedup reasons only.
Value

A Matrix like x but with no explicit zeros, i.e., !any(x@x == 0), always inheriting from CsparseMatrix.

Note

When a sparse matrix is the result of matrix multiplications, you may want to consider combining drop0() with zapsmall(), see the example.

See Also

spMatrix, class sparseMatrix

Examples

```r
m <- spMatrix(10, 20, i = 1:8, j = 2:9, x = c(0:2, 3:-1))
print(m)
drop0(m)

## A larger example:
t5 <- new("dsCMatrix", Dim = c(5L, 5L), uplo = "L",
x = c(10, 1, 3, 10, 1, 10, 1, 10, 10),
i = c(0L, 2L, 4L, 1L, 3L, 2L, 4L, 3L, 4L),
p = c(0L, 3L, 5L, 7L))
TT <- kronecker(t5, kronecker(kronecker(t5, t5), t5))
IT <- solve(TT)
I. <- TT %*% IT ; nnzero(I.) # 697 ( = 625 + 72 )
I.. <- drop0(zapsmall(I.))
## which actually can be more efficiently achieved by
I.. <- drop0(I., tol = 1e-15)
stopifnot(all(I.. == Diagonal(625)),
          nnzero(I..) == 625)
```

dsCMatric-class

**Numeric Symmetric Sparse (column compressed) Matrices**

Description

The dsCMatric class is a class of symmetric, sparse numeric matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The dstMatrix class is the class of symmetric, sparse numeric matrices in triplet format.

Objects from the Class

Objects can be created by calls of the form new("dsCMatrix", ...) or new("dsTMatrix", ...), or automatically via e.g., as(*, "symmetricMatrix"), or (for dsCMatric) also from Matrix().

Creation “from scratch” most efficiently happens via sparseMatrix(*, symmetric=TRUE).
**Slots**

- **uplo**: A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored.
- **i**: Object of class "integer" of length nnZ (half number of non-zero elements). These are the row numbers for each non-zero element in the lower triangle of the matrix.
- **p**: (only in class "dsCMatrix"): an integer vector for providing pointers, one for each column, see the detailed description in `CsparseMatrix`.
- **j**: (only in class "dsTMatrix"): Object of class "integer" of length nnZ (as i). These are the column numbers for each non-zero element in the lower triangle of the matrix.
- **x**: Object of class "numeric" of length nnZ – the non-zero elements of the matrix (to be duplicated for full matrix).
- **factors**: Object of class "list" - a list of factorizations of the matrix.
- **Dim**: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Extends**

Both classes extend classes and `symmetricMatrix dsparseMatrix` directly; `dsCMatrix` further directly extends `CsparseMatrix`, where `dsTMatrix` does `TsparseMatrix`.

**Methods**

- **solve** signature(a = "dsCMatrix", b = "..."): x <- solve(a,b) solves $Ax = b$ for $x$; see `solve-methods`.
- **chol** signature(x = "dsCMatrix", pivot = "logical"): Returns (and stores) the Cholesky decomposition of x, see chol.
- **Cholesky** signature(A = "dsCMatrix",
  ...): Computes more flexibly Cholesky decompositions, see Cholesky.
- **determinant** signature(x = "dsCMatrix", logarithm = "missing"): Evaluate the determinant of x on the logarithm scale. This creates and stores the Cholesky factorization.
- **determinant** signature(x = "dsCMatrix", logarithm = "logical"): Evaluate the determinant of x on the logarithm scale or not, according to the logarithm argument. This creates and stores the Cholesky factorization.
- **t** signature(x = "dsCMatrix"): Transpose. As for all symmetric matrices, a matrix for which the upper triangle is stored produces a matrix for which the lower triangle is stored and vice versa, i.e., the uplo slot is swapped, and the row and column indices are interchanged.
- **t** signature(x = "dsTMatrix"): Transpose. The uplo slot is swapped from "U" to "L" or vice versa, as for a "dsCMatrix", see above.
- **coerce** signature(from = "dsCMatrix", to = "dgTMatrix")
- **coerce** signature(from = "dsCMatrix", to = "dgeMatrix")
- **coerce** signature(from = "dsCMatrix", to = "matrix")
- **coerce** signature(from = "dsTMatrix", to = "dgeMatrix")
- **coerce** signature(from = "dsTMatrix", to = "dsCMatrix")
- **coerce** signature(from = "dsTMatrix", to = "dsyMatrix")
- **coerce** signature(from = "dsTMatrix", to = "matrix")

**See Also**

Classes `dgCMatrix, dgTMatrix, dgeMatrix` and those mentioned above.
Examples

```r
mm <- Matrix(toeplitz(c(10, 0, 1, 0, 3)), sparse = TRUE)
mM # automatically dsCMatrix
str(mM)

## how would we go from a manually constructed Tsparse* :
mT <- as(mm, "dgTMatrix")

## Either
(symM <- as(mT, "symmetricMatrix"))# dsT  
(symC <- as(symM, "CsparseMatrix"))# dsC
## or
sC <- Matrix(mT, sparse=TRUE, forceCheck=TRUE)

sym2 <- as(symC, "TsparseMatrix")
## --> the same as 'symM', a "dsTMatrix"
```

dsparseMatrix-class "Virtual Class "dsparseMatrix" of Numeric Sparse Matrices"

Description

The Class "dsparseMatrix" is the virtual (super) class of all numeric sparse matrices.

Slots

- Dim: the matrix dimension, see class "Matrix".
- Dimnames: see the "Matrix" class.
- x: a numeric vector containing the (non-zero) matrix entries.

Extends

Class "dMatrix" and "sparseMatrix", directly.
Class "Matrix", by the above classes.

See Also

the documentation of the (non virtual) sub classes, see showClass("dsparseMatrix"); in particular, dgTMatrix, dgCMatrix, and dgRMatrix.

Examples

showClass("dsparseMatrix")
**dsRMMatrix-class**

**Symmetric Sparse Compressed Row Matrices**

**Description**

The `dsRMMatrix` class is a class of symmetric, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

**Objects from the Class**

These "..RMatrix" classes are currently still mostly unimplemented!

Objects can be created by calls of the form `new("dsRMMatrix", ...)`.

**Slots**

- `uplo`: A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored. At present only the lower triangle form is allowed.
- `j`: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
- `p`: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.
- `factors`: Object of class "list" - a list of factorizations of the matrix.
- `x`: Object of class "numeric" - the non-zero elements of the matrix.
- `dim`: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.
- `dimnames`: List of length two, see `Matrix`.

**Extends**

Classes `RsparseMatrix`, `dsparseMatrix` and `symmetricMatrix`, directly.

Class "dMani", by class "dsparseMatrix", class "dsparseMa", by class "dsparseMatrix" or "RsparseMatrix"; class "compMatrix" by class "symmetricMatrix" and of course, class "Matrix".

**Methods**

- `forceSymmetric` signature(x = "dsRMMatrix", uplo = "missing"): a trivial method just returning x
- `forceSymmetric` signature(x = "dsRMMatrix", uplo = "character"): if uplo == x@uplo, this trivially returns x; otherwise t(x).
- `coerce` signature(from = "dsCMat", to = "dsRMMatrix")

**See Also**

the classes `dgCMat`, `dgTMatrix`, and `dgeMatrix`. 
Examples

```r
(m0 <- new("dsyMatrix"))
m2 <- new("dsyMatrix", Dim = c(2L, 2L),
        x = c(3, 1), j = c(1L, 1L), p = 0:2)

stopifnot(colSums(as(m2, "TsparseMatrix")) == 3:4)

str(m2)

(ds2 <- forceSymmetric(diag(2))) # dsys

dR <- as(ds2, "RsparseMatrix")
dR # dsyMatrix
```

**dysyMatrix-class**  
**Symmetric Dense Numeric Matrices**

Description

The "dsyMatrix" class is the class of symmetric, dense matrices in non-packed storage and "dpMatrix" is the class of symmetric dense matrices in packed storage. Only the upper triangle or the lower triangle is stored.

Objects from the Class

Objects can be created by calls of the form `new("dsyMatrix", ...)`.  

Slots

- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- `x`: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.
- `Dim,Dimnames`: The dimension (a length-2 "integer") and corresponding names (or NULL), see the `Matrix`.
- `factors`: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

"dsyMatrix" extends class "dgeMatrix", directly, whereas  
"dpMatrix" extends class "ddenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, indirectly, use `showClass("dsyMatrix"), e.g., for details.

Methods

- `coerce` signature(from = "ddenseMatrix", to = "dgeMatrix")
- `coerce` signature(from = "dpMatrix", to = "matrix")
- `coerce` signature(from = "dsyMatrix", to = "matrix")
- `coerce` signature(from = "dsyMatrix", to = "dpMatrix")
- `coerce` signature(from = "dpMatrix", to = "dsyMatrix")
The `dtCMatrix` class is a class of triangular, sparse matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order. The `dtTMatrix` class is a class of triangular, sparse matrices in triplet format.

Objects from the Class

Objects can be created by calls of the form `new("dtCMatrix", ...)` or calls of the form `new("dtTMatrix", ...)`, but more typically automatically via `Matrix()` or coercion such as `as(x, "dtCMatrix")`.

Slots

- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- `diag`: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.
- `p`: (only present in "dtCMatrix"): an integer vector for providing pointers, one for each column, see the detailed description in `CsparseMatrix`.

Examples

```r
## Only upper triangular part matters (when uplo == "U" as per default)
(sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA, 32, 77)))
str(t(sy2)) # uplo = "L", and the lower tri. (i.e. NA is replaced).

cholesky(sy2) #-> "Cholesky" matrix
(sp2 <- pack(sy2)) # a "dsyMatrix"

## Coercing to dpoMatrix gives invalid object:
sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7))
try(as(sy3, "dpoMatrix")) # -> error: not positive definite
```
i: Object of class "integer" of length nnzero (number of non-zero elements). These are the row
numbers for each non-zero element in the matrix.

j: Object of class "integer" of length nnzero (number of non-zero elements). These are the
column numbers for each non-zero element in the matrix. (Only present in the dtTMatrix
class.)

x: Object of class "numeric" - the non-zero elements of the matrix.

Dim, Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited
from the Matrix, see there.

Extends

Class "dgCMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix",
"sparseMatrix", and more by class "dgCMatrix" etc, see the examples.

Methods

c coerce signature(from = "dtCMatrix", to = "dgTMatrix")
c coerce signature(from = "dtCMatrix", to = "dgeMatrix")
c coerce signature(from = "dtTMatrix", to = "dgeMatrix")
c coerce signature(from = "dtTMatrix", to = "dtrMatrix")
c coerce signature(from = "dtTMatrix", to = "matrix")
s solve signature(a = "dtCMatrix", b = "...."): sparse triangular solve (aka "backsolve" or
"forwardsolve"), see solve-methods.
t signature(x = "dtCMatrix"): returns the transpose of x
t signature(x = "dtTMatrix"): returns the transpose of x

See Also

Classes dgCMatrix, dgTMatrix, dgeMatrix, and dtrMatrix.

Examples

showClass("dtCMatrix")
showClass("dtTMatrix")
t1 <- new("dtTMatrix", x= c(3,7), i= 0:1, j=3:2, Dim= as.integer(c(4,4)))
t1
## from 0-diagonal to unit-diagonal (low-level step):
tu <- t1; tu@diag <- "U"
tu
(cu <- as(tu, "dtCMatrix"))
str(cu)# only two entries in @i and @x
stopifnot(cu@i == 1:0,
  all(2 * symmpart(cu) == Diagonal(4) + forceSymmetric(cu)))
t1[1,2:3] <- -1:-2
diag(t1) <- 10*c(1:2,3:2)
t1 # still triangular
(it1 <- solve(t1))
t1. <- solve(it1)
all(abs(t1 - t1.) < 10 * .Machine$double.eps)
## dtpMatrix-class

Packed Triangular Dense Matrices - "dtpMatrix"

### Description

The "dtpMatrix" class is the class of triangular, dense, numeric matrices in packed storage. The "dtrMatrix" class is the same except in nonpacked storage.

### Objects from the Class

Objects can be created by calls of the form `new("dtpMatrix", ...)` or by coercion from other classes of matrices.

### Slots

- **uplo**: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- **diag**: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.
- **x**: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order. For a packed square matrix of dimension \(d \times d\), `length(x)` is of length \(d(d+1)/2\) (also when `diag == "U"`).
- **Dim,Dimnames**: The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the `Matrix`, see there.

### Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix" and more by class "ddenseMatrix" etc, see the examples.
Methods

```r
%*% signature(x = "dtpMatrix", y = "dgeMatrix"): Matrix multiplication; ditto for several other signature combinations, see showMethods("%*%", class = "dtpMatrix").
coerce signature(from = "dtpMatrix", to = "dtrMatrix")
coerce signature(from = "dtpMatrix", to = "matrix")
determinant signature(x = "dtpMatrix", logarithm = "logical"): the determinant(x) trivially is prod(diag(x)), but computed on log scale to prevent over- and underflow.
diag signature(x = "dtpMatrix"): ...
norm signature(x = "dtpMatrix", type = "character"): ...
rcond signature(x = "dtpMatrix", norm = "character"): ...
solve signature(a = "dtpMatrix", b = "..."): efficiently using internal backsolve or forwardsolve, see solve-methods.
t signature(x = "dtpMatrix"): t(x) remains a "dtpMatrix", lower triangular if x is upper triangular, and vice versa.
```

See Also

Class dtrMatrix

Examples

```r
showClass("dtrMatrix")
example("dtrMatrix-class", echo=FALSE)
(p1 <- as(T2, "dtpMatrix"))
str(p1)
(pp <- as(T, "dtpMatrix"))
ip1 <- solve(p1)
stopifnot(length(p1@x) == 3, length(pp@x) == 3, 
  p1 @ uplo == T2 @ uplo, pp @ uplo == T @ uplo, 
  identical(t(pp), p1), identical(t(p1), pp), 
  all((.d <- p1 - T2) == 0), is(.d, "dtpMatrix"), 
  all((.u.d <- pp - T) == 0), is(.u.d, "dtpMatrix"), 
  l.d@uplo == T2@uplo, u.d@uplo == T@uplo, 
  identical(t(ip1), solve(pp)), is(ip1, "dtpMatrix"), 
  all.equal(as(solve(p1,p1), "diagonalMatrix"), Diagonal(2)))
```

Description

The dtrMatrix class is a class of triangular, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

Objects from the Class

This class is currently still mostly unimplemented!

Objects can be created by calls of the form `new("dtrMatrix", ...).`
Slots

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. At present only the lower triangle form is allowed.

diag: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see triangularMatrix.

j: Object of class "integer" of length nnzero(.) (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

p: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row. (Only present in the dsRMatrix class.)

x: Object of class "numeric" - the non-zero elements of the matrix.

Dim: The dimension (a length-2 "integer")

Dimnames: corresponding names (or NULL), inherited from the Matrix, see there.

Extends

Class "dgRMatrix", directly. Class "dsparseMatrix", by class "dgRMatrix". Class "dMatrix", by class "dgRMatrix". Class "sparseMatrix", by class "dgRMatrix". Class "Matrix", by class "dgRMatrix".

Methods

No methods currently with class "dsRMatrix" in the signature.

See Also

Classes dgCMatrix, dgTMatrix, dgeMatrix

Examples

(m0 <- new("dtRMatrix"))
(m2 <- new("dtRMatrix", Dim = c(2L, 2L),
      x = c(5, 1:2), p = c(0L, 2:3), j= c(0:1, 1L)))
str(m2)
(m3 <- as(Diagonal(2), "RsparseMatrix"))# --> dtRMatrix

---

dtrMatrix-class  Triangular, dense, numeric matrices

Description

The "dtrMatrix" class is the class of triangular, dense, numeric matrices in nonpacked storage. The "dtpMatrix" class is the same except in packed storage.

Objects from the Class

Objects can be created by calls of the form new("dtrMatrix", ...).
Slots

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

diag: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see triangularMatrix.

x: Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.

Dim: Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.

Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "Matrix" and others, by class "ddenseMatrix".

Methods

Among others (such as matrix products, e.g. ?crossprod-methods),

coerce signature(from = "dgeMatrix", to = "dtrMatrix")
coerce signature(from = "dtrMatrix", to = "matrix")
coerce signature(from = "ltrMatrix", to = "dtrMatrix")
coerce signature(from = "dtrMatrix", to = "matrix")
coerce signature(from = "matrix", to = "dtrMatrix")
norm signature(x = "dtrMatrix", type = "character")
rcond signature(x = "dtrMatrix", norm = "character")
solve signature(a = "dtrMatrix", b = "...") efficiently use a "forwardsolve" or backsolve for a lower or upper triangular matrix, respectively, see also solve-methods.

+,-,*,...,==,>=,... all the Ops group methods are available. When applied to two triangular matrices, these return a triangular matrix when easily possible.

See Also

Classes ddenseMatrix, dtpMatrix, triangularMatrix

Examples

(m <- rbind(2:3, 0:-1))
(M <- as(m, "dgeMatrix"))

(t <- as(M, "dtrMatrix")) # upper triangular is default
(T2 <- as(t(M), "dtrMatrix"))
stopifnot(T@uplo == "U", T2@uplo == "L", identical(T2, t(T)))
**expand**

**Expand a Decomposition into Factors**

**Description**

Expands decompositions stored in compact form into factors.

**Usage**

`expand(x, ...)`

**Arguments**

- `x`: a matrix decomposition.
- `...`: further arguments passed to or from other methods.

**Details**

This is a generic function with special methods for different types of decompositions, see `showMethods(expand)` to list them all.

**Value**

The expanded decomposition, typically a list of matrix factors.

**Note**

Factors for decompositions such as `lu` and `qr` can be stored in a compact form. The function `expand` allows all factors to be fully expanded.

**See Also**

The LU `lu`, and the Cholesky decompositions which have expand methods; `facmul`.

**Examples**

```r
(x <- Matrix(round(rnorm(9),2), 3, 3))
(ex <- expand(lux <- lu(x)))
```
**Description**

Compute the exponential of a matrix.

**Usage**

\[
\text{expm}(x)
\]

**Arguments**

\[x\] a matrix, typically inheriting from the \texttt{dMatrix} class.

**Details**

The exponential of a matrix is defined as the infinite Taylor series \[ \text{expm}(A) = I + A + A^2/2! + A^3/3! + \ldots \] (although this is definitely not the way to compute it). The method for the \texttt{dgeMatrix} class uses Ward’s diagonal Pade’ approximation with three step preconditioning.

**Value**

The matrix exponential of \[x\].

**Note**

The \texttt{expm} package contains newer (partly faster and more accurate) algorithms for \texttt{expm()} and includes \texttt{logm} and \texttt{sqrtm}.

**Author(s)**

This is a translation of the implementation of the corresponding Octave function contributed to the Octave project by A. Scottedward Hodel <A. S. Hodel@Eng. Auburn. Edu>. A bug in there has been fixed by Martin Maechler.

**References**

- \url{http://en.wikipedia.org/wiki/Matrix_exponential}

**See Also**

\texttt{Schur}; additionally, \texttt{expm}, \texttt{logm}, etc in package \texttt{expm}. 
externalFormats

Examples

```r
(m1 <- Matrix(c(1,0,1), nc = 2))
(e1 <- expm(m1)); e <- exp(1)
stopifnot(all.equal(e1@x, c(e,0,e,e), tolerance = 1e-15))
(m2 <- Matrix(c(-49, -64, 24, 31), nc = 2))
(e2 <- expm(m2))
(m3 <- Matrix(cbind(0, rbind(5*diag(3), 0)))) # sparse!
(e3 <- expm(m3)) # upper triangular
```

Description

Read matrices stored in the Harwell-Boeing or MatrixMarket formats or write `spmatrix` objects to one of these formats.

Usage

```r
readHB(file)
readMM(file)
writeMM(obj, file, ...)
```

Arguments

- `obj` a real sparse matrix
- `file` for `writeMM` - the name of the file to be written. For `readHB` and `readMM` the name of the file to read, as a character scalar. The names of files storing matrices in the Harwell-Boeing format usually end in ".rua" or ".rsa". Those storing matrices in the MatrixMarket format usually end in ".mtx".
- `...` optional additional arguments. Currently none are used in any methods.

Value

The `readHB` and `readMM` functions return an object that inherits from the "Matrix" class. Methods for the `writeMM` generic functions usually return `NULL` and, as a side effect, the matrix `obj` is written to file in the MatrixMarket format (`writeMM`).

Note

The Harwell-Boeing format is older and less flexible than the MatrixMarket format. The function `writeHB` was deprecated and has now been removed. Please use `writeMM` instead.

A very simple way to export small sparse matrices `S`, is to use `summary(S)` which returns a `data.frame` with columns `i`, `j`, and possibly `x`, see summary in `spmatrix-class`, and an example below.

References

http://math.nist.gov/MatrixMarket
http://www.cise.ufl.edu/research/sparse/matrices
Examples

```r
cf <- readMM(system.file("external/pores_1.mtx", package = "Matrix"))
cf
```

## Not run:
## NOTE: The following examples take quite some time
## even on a fast internet connection:
if(FALSE) # the URL has been corrected, but we need an un-tar step!
str(sm <- readHB(gzcon(url("http://www.cise.ufl.edu/research/sparse/RE/Boeing/msc00726.tar.gz"))))

str(jg1009 <- readMM(gzcon(url("ftp://math.nist.gov/pub/MatrixMarket2/Harwell-Boeing/counterex/jg1009.mtx.gz"))))

## End(Not run)
data(KNex)
writeMM(KNex$mm, "mm.mtx")

## very simple export - in triplet format - to text file:
data(CAex)
s.CA <- summary(CAex)
message("writing to ", outf <- tempfile())
write.table(s.CA, file = outf, row.names=FALSE)
## and read it back -- showing off sparseMatrix():
dd <- read.table(outf, header=TRUE)
mm <- do.call(sparseMatrix, dd)
stopifnot(all.equal(mm, CAex, tolerance=1e-15))
```

facmul

### Multiplication by Decomposition Factors

**Description**

Performs multiplication by factors for certain decompositions (and allows explicit formation of those factors).

**Usage**

`facmul(x, factor, y, transpose, left, ...)`

**Arguments**

- `x` a matrix decomposition. No missing values or IEEE special values are allowed.
- `factor` an indicator for selecting a particular factor for multiplication.
- `y` a matrix or vector to be multiplied by the factor or its transpose. No missing values or IEEE special values are allowed.
- `transpose` a logical value. When FALSE (the default) the factor is applied. When TRUE the transpose of the factor is applied.
left  a logical value. When TRUE (the default) the factor is applied from the left. When FALSE the factor is applied from the right.

... the method for "qr.Matrix" has additional arguments.

Value

the product of the selected factor (or its transpose) and y

NOTE

Factors for decompositions such as lu and qr can be stored in a compact form. The function facmul allows multiplication without explicit formation of the factors, saving both storage and operations.

References

Examples

library(Matrix)
x <- Matrix(rnorm(9), 3, 3)
## Not run:
qrx <- qr(x)  # QR factorization of x
y <- rnorm(3)
facmul(qr(x), factor = "Q", y)  # form Q y
## End(Not run)

forceSymmetric

Force a Matrix to 'symmetricMatrix' Without Symmetry Checks

Description

Force a square matrix x to a symmetricMatrix, without a symmetry check as it would be applied for as(x, "symmetricMatrix").

Usage

forceSymmetric(x, uplo)

Arguments

x  any square matrix (of numbers), either ""traditional"" (matrix) or inheriting from Matrix.

uplo  optional string, "U" or "L" indicating which "triangle" half of x should determine the result. The default is "U" unless x already has a uplo slot (i.e., when it is symmetricMatrix, or triangularMatrix), where the default will be x@uplo.

Value

a square matrix inheriting from class symmetricMatrix.
See Also

`symmpart` for the symmetric part of a matrix, or the coercions as(x, <symmetricMatrix class>).

Examples

```r
## Hilbert matrix
i <- 1:6
h6 <- 1/outer(i - 1L, i, "+")
sd <- sqrt(diag(h6))
hh <- t(h6/sd)/sd # theoretically symmetric
isSymmetric(hh, tol=0) # FALSE; hence
try(as(hh, "symmetricMatrix") ) # fails, but this works fine:
H6 <- forceSymmetric(hh)

## result can be pretty surprising:
(M <- Matrix(1:36, 6))
forceSymmetric(M) # symmetric, hence very different in lower triangle
(tm <- tril(M))
forceSymmetric(tm)
```

formatSparseM

Formatting Sparse Numeric Matrices Utilities

Description

Utilities for formatting sparse numeric matrices in a flexible way. These functions are used by the `format` and `print` methods for sparse matrices and can be applied as well to standard R matrices. Note that all arguments but the first are optional.

`formatSparseM()` is the main “workhorse” of `formatSpMatrix`, the format method for sparse matrices.

`.formatSparseSimple()` is a simple helper function, also dealing with (short/empty) column names construction.

Usage

```r
formatSparseM(x, zero.print = "+", align = c("fancy", "right"),
m = as(x,"matrix"), asLogical=NULL, digits=NULL,
  cx, iN0, dn = dimnames(m))

.formatSparseSimple(m, asLogical=FALSE, digits=NULL,
  col.names, note.dropping.colnames = TRUE,
  dn=dimnames(m))
```

Arguments

- `x` an R object inheriting from class `sparseMatrix`.
- `zero.print` character which should be used for structural zeroes. The default "+" may occasionally be replaced by "+" (blank); using "0" would look almost like print()ing of non-sparse matrices.
- `align` a string specifying how the zero.print codes should be aligned, see `formatSpMatrix`.
generalMatrix-class

m (optional) a (standard \( \text{R} \)) matrix version of \( x \).

asLogical should the matrix be formatted as a logical matrix (or rather as a numeric one); mostly for formatSparseM().

digits significant digits to use for printing, see print.default.

cx (optional) character matrix; a formatted version of \( x \), still with strings such as "0.00" for the zeros.

in0 (optional) integer vector, specifying the location of the non-zeroes of \( x \).

col.names, note.dropping.colnames see formatSpMatrix.

dn dimnames to be used; a list (of length two) with row and column names (or NULL).

Value

a character matrix like cx, where the zeros have been replaced with (padded versions of) zero.print. As this is a dense matrix, do not use these functions for really large (really) sparse matrices!

Author(s)

Martin Maechler

See Also

formatSpMatrix which calls formatSparseM() and is the format method for sparse matrices.

printSpMatrix which is used by the (typically implicitly called) show and print methods for sparse matrices.

Examples

m <- suppressWarnings(matrix(c(0, 3.2, 0, 0, 11,0,0,0,0,-7,0), 4,9))
fM <- formatSparseM(m)
noquote(fm)
## nice, but this is nicer :
print(fm, quote=FALSE, right=TRUE)
## and "the same" as :
Matrix(m)

## align = "right" is cheaper --> the "." are not aligned:
noquote(f2 <- formatSparseM(m,align="r"))
stopifnot(f2 == fm | m == 0, dim(f2) == dim(m),
 (f2 == ".") == (m == 0))

---

generalMatrix-class  Class "generalMatrix" of General Matrices

Description

Virtual class of "general" matrices; i.e., matrices that do not have a known property such as symmetric, triangular, or diagonal.
Objects from the Class

A virtual Class: No objects may be created from it.

Slots

- factors
- Dim
- Dimnames: all slots inherited from compMatrix; see its description.

Extends

Class "compMatrix", directly. Class "Matrix", by class "compMatrix".

See Also

Classes compMatrix, and the non-general virtual classes: symmetricMatrix, triangularMatrix, diagonalMatrix.

---

graph-sparseMatrix  
Conversions "graph" <--> (sparse) Matrix

Description

The Matrix package has supported conversion from and to "graph" objects from (Bioconductor) package graph since summer 2005, via the usual as(. , "<class>") coercion,

as(from, Class)

Since 2013, this functionality is further exposed as the graph2T() and T2graph() functions (with further arguments than just from), which convert graphs to and from the triplet form of sparse matrices (of class "TsparseMatrix").

Usage

graph2T(from, use.weights = )
T2graph(from, need.uniq = is_not_uniqT(from), edgemode = NULL)

Arguments

- from  
  for graph2T(), an R object of class "graph";
  for T2graph(), a sparse matrix inheriting from "TsparseMatrix".
- use.weights  
  logical indicating if weights should be used, i.e., equivalently the result will be numeric, i.e. of class dgTMatrix; otherwise the result will be ngTMatrix or nsTMatrix, the latter if the graph is undirected. The default looks if there are weights in the graph, and if any differ from 1, weights are used.
- need.uniq  
  a logical indicating if from may need to be internally “uniqified”; do not set this and hence rather use the default, unless you know what you are doing!
- edgemode  
  one of NULL, "directed", or "undirected". The default NULL looks if the matrix is symmetric and assumes "undirected" in that case.
**Description**

Generate the \( n \times n \) symmetric Hilbert matrix. Because these matrices are ill-conditioned for moderate to large \( n \), they are often used for testing numerical linear algebra code.

**Usage**

```r
Hilbert(n)
```

**Arguments**

- \( n \) a non-negative integer.

**Value**

the \( n \times n \) symmetric Hilbert matrix as a "dpoMatrix" object.

**See Also**

the class `dpoMatrix`
Methods for function `image` in package `Matrix`. An image of a matrix simply color codes all matrix entries and draws the \( n \times m \) matrix using an \( n \times m \) grid of (colored) rectangles.

Usage

```r
## S4 method for signature 'dgTMatrix'
image(x,
xlim = c(1, di[2]),
ylim = c(di[1], 1), aspect = "iso",
sub = sprintf("Dimensions: \%d x \%d", di[1], di[2]),
lab = "Column", ylab = "Row", cuts = 15,
useRaster = FALSE,
useAbs = NULL, colorkey = !useAbs,
col.regions = NULL,
lwd = NULL, ...)
```

Arguments

- **x**: a Matrix object, i.e., fulfilling `is(x, "Matrix")`.
- **xlim**, **ylim**: x- and y-axis limits; may be used to “zoom into” matrix. Note that \( x, y \) “feel reversed”: \( y \text{lim} \) is for the rows (= 1st index) and \( x \text{lim} \) for the columns (= 2nd index). For convenience, when the limits are integer valued, they are both extended by \( \pm 0.5 \); also, \( y \text{lim} \) is always used decreasingly.
- **aspect**: aspect ratio specified as number (\( y/x \)) or string; see `levelplot`.
- **sub**, **xlab**, **ylab**: axis annotation with sensible defaults; see `plot.default`.
- **cuts**: number of levels the range of matrix values would be divided into.
- **useRaster**: logical indicating if raster graphics should be used (instead of the tradition rectangle vector drawing). If true, `panel.levelplot.raster` (from `lattice` package) is used, and the colorkey is also done via rasters, see also `levelplot` and possibly `grid.raster`.

Note that using raster graphics may often be faster, but can be slower, depending on the matrix dimensions and the graphics device (dimensions).

- **useAbs**: logical indicating if `abs(x)` should be shown; if TRUE, the former (implicit) default, the default col.regions will be grey colors (and no colorkey drawn). The default is FALSE unless the matrix has no negative entries.
- **colorkey**: logical indicating if a color key aka ‘legend’ should be produced. Default is to draw one, unless `useAbs` is true. You can also specify a `list`, see `levelplot`, such as `list(raster=True)` in the case of rastering.
- **col.regions**: vector of gradually varying colors; see `levelplot`. 
**image-methods**

lwd (only used when useRaster is false:) non-negative number or NULL (default), specifying the line-width of the rectangles of each non-zero matrix entry (drawn by **grid.rect**). The default depends on the matrix dimension and the device size.

... further arguments passed to methods and **levelplot**, notably at for specifying (possibly non equidistant) cut values for dividing the matrix values (superseding cuts above).

**Methods**

All methods currently end up calling the method for the **dgTMatrix** class. Use **showMethods(image)** to list them all.

**Examples**

```r
showMethods(image)
## If you want to see all the methods' implementations:
showMethods(image, incl=TRUE, inherit=FALSE)

data(CAex)
image(CAex, main = "image(CAex)"")
image(CAex, useAbs=TRUE, main = "image(CAex, useAbs=TRUE)")

cCA <- Cholesky(crossprod(CAex), Imult = .01)
image(cCA, main="Cholesky(crossprod(CAex), Imult = .01)"")
image(cCA, useAbs=TRUE)

data(USCounties)
image(USCounties)# huge
image(sign(USCounties))## just the pattern
  # how the result looks, may depend heavily on
  # the device, screen resolution, antialiasing etc
  # e.g. x11(type="Xlib") may show very differently than cairo-based

## Drawing borders around each rectangle;
  # again, viewing depends very much on the device:
  image(USCounties[1:400,1:200], lwd=.1)
## Using (xlim,ylim) has advantage: matrix dimension and (col/row) indices:
image(USCounties, c(1,200), c(1,400), lwd=.1)
image(USCounties, c(1,300), c(1,200), lwd=.5)
image(USCounties, c(1,300), c(1,200), lwd=.01)

if(doExtras <- interactive() || nzchar(Sys.getenv("R_MATRIX_CHECK_EXTRA")) || identical("true", unname(Sys.getenv("R_PKG_CHECKING_doExtras")))) {
  ## Using raster graphics: For PDF this would give a 77 MB file, 
  ## however, for such a large matrix, this is typically considerably
  ## *slower* (than vector graphics rectangles) in most cases:
  if(doPNG <- !dev.interactive())
    png("image-USCounties-raster.png", width=3200, height=3200)
image(USCounties, useRaster = TRUE) # should not suffer from anti-aliasing
  if(doPNG)
    dev.off()
  ## and now look at the *.png image in a viewer you can easily zoom in and out 
}#only if(doExtras)
```
Virtual Class "index" - Simple Class for Matrix Indices

Description

The class "index" is a virtual class used for indices (in signatures) for matrix indexing and sub-assignment of "Matrix" matrices.

In fact, it is currently implemented as a simple class union (setClassUnion) of "numeric", "logical" and "character".

Objects from the Class

Since it is a virtual Class, no objects may be created from it.

See Also

[<methods>, and
Subassign-methods, also for examples.

Examples

showClass("index")

Index matrices

Description

The "indMatrix" class is the class of index matrices, stored as 1-based integer index vectors. An index matrix is a matrix with exactly one non-zero entry per row. Index matrices are useful for mapping observations to unique covariate values, for example.

Matrix (vector) multiplication with index matrices is equivalent to replicating and permuting rows, or "sampling rows with replacement", and is implemented that way in the Matrix package, see the ‘Details’ below.

Details

Matrix (vector) multiplication with index matrices from the left is equivalent to replicating and permuting rows of the matrix on the right hand side. (Similarly, matrix multiplication with the transpose of an index matrix from the right corresponds to selecting columns.) The crossproduct of an index matrix \( M \) with itself is a diagonal matrix with the number of entries in each column of \( M \) on the diagonal, i.e., \( M'M = \text{Diagonal}(x=\text{table}(M@perm)) \).

Permutation matrices (of class \( \text{pmatrix} \)) are special cases of index matrices: They are square, of dimension, say, \( n \times n \), and their index vectors contain exactly all of \( 1:n \).

While "row-indexing" (of more than one row or using \( \text{drop=} \text{FALSE} \)) stays within the "indMatrix" class, all other subsetting/indexing operations ("column-indexing", including \( \text{diag} \)) on "indMatrix" objects treats them as nonzero-pattern matrices ("\( \text{ngTMatrix} \)" specifically), such that non-matrix subsetting results in \( \text{logical} \) vectors. Sub-assignment \( (M[i,j] \leftarrow v) \) is not sensible and hence an error for these matrices.
Objects from the Class

Objects can be created by calls of the form `new("indMatrix", ...)` or by coercion from an integer index vector, see below.

Slots

- `perm`: An integer, 1-based index vector, i.e. an integer vector of length `Dim[1]` whose elements are taken from `1:Dim[2]`.
- `Dim`: Object of class "integer". The dimensions of the matrix which must skinny, i.e., the first dimension has to be at least as large as the second.
- `Dimnames`: list of length two; each component containing NULL or a character vector length equal the corresponding `Dim` element.

Extends

Class "sparseMatrix" and "generalMatrix", directly.

Methods

- `%*%` signature(`x = "matrix", y = "indMatrix"`) and other signatures (use `showMethods("%*%", class="indMatrix")`): ...
- `coerce` signature(`from = "integer", to = "indMatrix"`): This enables typical "indMatrix" construction, given an index vector from elements in `1:Dim[2]`, see the first example.
- `coerce` signature(`from = "numeric", to = "indMatrix"`): a user convenience, to allow as(perm, "indMatrix") for numeric perm with integer values.
- `coerce` signature(`from = "list", to = "indMatrix"`): The list must have two (integer-valued) entries: the first giving the index vector with elements in `1:Dim[2]`, the second giving `Dim[2]`. This allows "indMatrix" construction for cases in which the values represented by the rightmost column(s) are not associated with any observations, i.e., in which the index does not contain values `Dim[2]`, `Dim[2]-1`, `Dim[2]-2`, ...
- `coerce` signature(`from = "indMatrix", to = "matrix"`): coercion to a traditional FALSE/TRUE matrix of mode logical.
- `coerce` signature(`from = "indMatrix", to = "ngTMatrix"`): coercion to sparse logical matrix of class `ngTMatrix`.
- `t` signature(`x = "indMatrix"`): return the transpose of the index matrix (which is no longer an indMatrix, but of class `ngTMatrix`.
- `colSums, colMeans, rowSums, rowMeans` signature(`x = "indMatrix"`): return the column or row sums or means.
- `rbind2` signature(`x = "indMatrix", y = "indMatrix"`): a fast method for rowwise catenation of two index matrices (with the same number of columns).
- `kronecker` signature(`X = "indMatrix", Y = "indMatrix"`): return the kronecker product of two index matrices, which corresponds to the index matrix of the interaction of the two.

Author(s)

Fabian Scheipl <...@uni-muenchen.de> building on existing "pMatrix", after a nice hike's conversation with Martin Maechler and tweaks by the latter.
invPerm

Inverse Permutation Vector

Description
From a permutation vector p, compute its inverse permutation vector.

Usage
invPerm(p, zero.p = FALSE, zero.res = FALSE)
Arguments

- **p**: an integer vector of length, say, n.
- **zero.p**: logical indicating if p contains values \(0:(n-1)\) or rather (by default, zero.p = FALSE) \(1:n\).
- **zero.res**: logical indicating if the result should contain values \(0:(n-1)\) or rather (by default, zero.res = FALSE) \(1:n\).

Value

an integer vector of the same length (n) as p. By default, (zero.p = FALSE, zero.res = FALSE), `invPerm(p)` is the same as `order(p)` or `sort.list(p)` and for that case, the function is equivalent to `invPerm`. <- function(p) { p[p] <- seq_along(p) ; p }.

Author(s)

Martin Maechler

See Also

the class of permutation matrices, `pMatrix`.

Examples

```r
p <- sample(10) # a random permutation vector
ip <- invPerm(p)
p[ip] # == 1:10
## they are indeed inverse of each other:
stopifnot(
  identical(p[ip], 1:10),
  identical(ip[p], 1:10),
  identical(invPerm(ip), p)
)
```

Description

Methods for function `is.na()`, `is.finite()`, and `is.infinite()` for all Matrices (objects extending the `Matrix` class):

- `x = "denseMatrix"` returns a "nMatrix" object of same dimension as x, with TRUE's whenever x is `NA`, finite, or infinite, respectively.
- `x = "sparseMatrix"` ditto.
Usage

```r
## S4 method for signature 'sparseMatrix'
is.na(x)
## S4 method for signature 'dsparseMatrix'
is.finite(x)
## S4 method for signature 'ddenseMatrix'
is.infinite(x)
## ...
## and for other classes
## S4 method for signature 'xMatrix'
anyNA(x)
## S4 method for signature 'nsparseMatrix'
anyNA(x)
## S4 method for signature 'sparseVector'
anyNA(x)
## S4 method for signature 'nsparseVector'
anyNA(x)
```

Arguments

- `x`: sparse or dense matrix or sparse vector (here; any R object in general).

See Also

`NA, is.na, is.finite, is.infinite; nMatrix, denseMatrix, sparseMatrix`

The `sparseVector` class.

Examples

```r
M <- Matrix(1:6, nrow=4, ncol=3,
dimnames = list(c("a", "b", "c", "d"), c("A", "B", "C")))
stopifnot(all(!is.na(M)))
M[2:3, 2] <- NA
is.na(M)
if(exists("anyNA", mode="function"))
  anyNA(M)

A <- spMatrix(10,20, i = c(1,3:8),
               j = c(2,9,6:10),
               x = 7*(1:7))
stopifnot(all(!is.na(A)))
inA <- is.na(A)
stopifnot(sum(inA) == 1+1+5)
```
is.null.DN

Are the Dimnames dn NULL-like?

Description
Are the dimnames dn NULL-like?
is.null.DN(dn) is less strict than is.null(dn), because it is also true (TRUE) when the dimnames dn are “like” NULL, or list(NULL, NULL), as they can easily be for the traditional R matrices (matrix) which have no formal class definition, and hence much freedom in how their dimnames look like.

Usage
is.null.DN(dn)

Arguments
dn dimnames() of a matrix-like R object.

Value
logical TRUE or FALSE.

Note
This function is really to be used on “traditional” matrices rather than those inheriting from Matrix, as the latter will always have dimnames list(NULL, NULL) exactly, in such a case.

Author(s)
Martin Maechler

See Also
is.null, dimnames, matrix.

Examples
m <- matrix(round(100 * rnorm(6)), 2, 3); m1 <- m2 <- m3 <- m4 <- m
dimnames(m1) <- list(NULL, NULL)
dimnames(m2) <- list(NULL, character())
dimnames(m3) <- rev(dimnames(m2))
dimnames(m4) <- rep(list(character()),2)
m4 # # prints absolutely identically to m

stopifnot(m == m1, m1 == m2, m2 == m3, m3 == m4,
  identical(capture.output(m) -> cm,
            capture.output(m1)),
  identical(cm, capture.output(m2)),
  identical(cm, capture.output(m3)),
  identical(cm, capture.output(m4)))
isSymmetric-methods  
Methods for Function isSymmetric in Package 'Matrix'

Description

isSymmetric(M) returns a logical indicating if M is a symmetric matrix. This (now) is a base function with a default method for the traditional matrices of class "matrix". Methods here are defined for virtual Matrix classes such that it works for all objects inheriting from class Matrix.

See Also

forceSymmetric, symmpart, and the formal class (and subclasses) "symmetricMatrix".

Examples

isSymmetric(Diagonal(4)) # TRUE of course
M <- Matrix(c(1,2,2,1), 2,2)
isSymmetric(M) # TRUE (and of formal class "dsyMatrix")
isSymmetric(as(M, "dgeMatrix")) # still symmetric, even if not "formally"
isSymmetric(triu(M)) # FALSE

# Look at implementations:
showMethods("isSymmetric", includeDefs=TRUE)# "ANY": base's S3 generic; 6 more

isTriangular  
isTriangular() and isDiagonal() Methods

Description

isTriangular(M) returns a logical indicating if M is a triangular matrix. Analogously, isDiagonal(M) is true if M is a diagonal matrix.

Contrary to isSymmetric(), these two functions are generically from package Matrix, and hence also define methods for traditional (class "matrix") matrices.

Usage

isDiagonal(object)

isTriangular(object, upper = NA, ...)

Arguments

object  any R object, typically a matrix (traditional or Matrix package).
upper   logical, one of NA (default), FALSE, or TRUE where the last two cases require a lower or upper triangular object to result in TRUE.
...     potentially further arguments for other methods.
Value
a ("scalar") logical, TRUE or FALSE, never NA. For isTriangular(), if the result is TRUE, it may contain an attribute (see attributes "kind," either "L" or "U" indicating if it is a lower or upper triangular matrix.

See Also
isSymmetric; formal class (and subclasses) "triangularMatrix" and "diagonalMatrix".

Examples
isTriangular(Diagonal(4))
## is TRUE: a diagonal matrix is also (both upper and lower) triangular
(M <- Matrix(c(1,2,0,1), 2,2))
isTriangular(M) # TRUE (*and* of formal class "dtrMatrix")
isTriangular(as(M, "dgeMatrix")) # still triangular, even if not "formally"
isTriangular(crossprod(M)) # FALSE
isDiagonal(matrix(c(2,0,0,1), 2,2)) # TRUE

---

Description
Computes Khatri-Rao products for any kind of matrices.

The Khatri-Rao product is a column-wise Kronecker product. Originally introduced by Khatri and Rao (1968), it has many different applications, see Liu and Trenkler (2008) for a survey. Notably, it is used in higher-dimensional tensor decompositions, see Bader and Kolda (2008).

Usage
KhatriRao(X, Y = X, FUN = "+", make.dimnames = FALSE)

Arguments

X, Y matrices of with the same number of columns.

FUN the (name of the) function to be used for the column-wise Kronecker products, see kronecker, defaulting to the usual multiplication.

make.dimnames logical indicating if the result should inherit dimnames from X and Y in a simple way.

Value
a "CsparseMatrix", say R, the Khatri-Rao product of X (n × k) and Y (m × k), is of dimension (n · m) × k, where the j-th column, R[, j] is the kronecker product kronecker(X[, j], Y[, j]).

Note
The current implementation is efficient for large sparse matrices.
Author(s)

Michael Cysouw, Univ. Marburg; minor tweaks by Martin Maechler.

kronecker.

Examples

```r
## Example with very small matrices:
m <- matrix(1:12,3,4)
d <- diag(1:4)
KhatriRao(m,d)
KhatriRao(d,m)
dimnames(m) <- list(LETTERS[1:3], letters[1:4])
KhatriRao(m,d, make.dimnames=TRUE)
KhatriRao(d,m, make.dimnames=TRUE)
dimnames(d) <- list(NULL, paste0("D", 1:4))
KhatriRao(m,d, make.dimnames=TRUE)
KhatriRao(d,m, make.dimnames=TRUE)
dimnames(d) <- list(paste0("D", 10*1:4), paste0("D", 1:4))
KhatriRao(m,d, make.dimnames=TRUE)
KhatriRao(d,m, make.dimnames=TRUE)

nm <- as(m,"nMatrix")
nm <- as(m,"nMatrix")
KhatriRao(nm,d, make.dimnames=TRUE)
KhatriRao(nd,nm, make.dimnames=TRUE)

stopifnot(dim(KhatriRao(m,d)) == c(nrow(m)*nrow(d), ncol(d)))
```

Koedinger-Ng Example Sparse Model Matrix and Response Vector

Description

A model matrix mm and corresponding response vector y used in an example by Koenker and Ng. The matrix mm is a sparse matrix with 1850 rows and 712 columns but only 8758 non-zero entries. It is a "dgCMatrix" object. The vector y is just numeric of length 1850.

Usage

data(KNex)
kronecker-methods

References

Examples

```r
data(KNex)
class(KNex$mm)
dim(KNex$mm)
image(KNex$mm)
str(KNex)

system.time( # a fraction of a second
  sparse.sol <- with(KNex, solve(crossprod(mm), crossprod(mm, y))))

head(round(sparse.sol,3))

## Compare with QR-based solution ("more accurate, but slightly slower"): system.time(
  sp.sol2 <- with(KNex, qr.coef(qr(mm), y)))

all.equal(sparse.sol, sp.sol2, tolerance = 1e-13) # TRUE
```

kronecker-methods

\textit{Methods for Function ‘kronecker’ in Package ‘Matrix’}

Description

Computes Kronecker products for objects inheriting from \textit{"Matrix"}.
In order to preserver sparseness, we treat \(0 \times \text{NA}\) as \(0\), not as \text{NA} as usually in \texttt{R} (and as used for the \texttt{base} function \texttt{kronecker}).

Methods

\texttt{kronecker signature(X = "Matrix", Y = "ANY")} ....
\texttt{kronecker signature(X = "ANY", Y = "Matrix")} ....
\texttt{kronecker signature(X = "diagonalMatrix", Y = "ANY")} ....
\texttt{kronecker signature(X = "sparseMatrix", Y = "ANY")} ....
\texttt{kronecker signature(X = "TsparseMatrix", Y = "TsparseMatrix")} ....
\texttt{kronecker signature(X = "dgTMatrix", Y = "dgTMatrix")} ....
\texttt{kronecker signature(X = "dtTMatrix", Y = "dtTMatrix")} ....
\texttt{kronecker signature(X = "indMatrix", Y = "indMatrix")} ....

Examples

```r
(t1 <- spMatrix(5,4, x= c(3,2,-7,11), i= 1:4, j=4:1)) # 5 x 4
t2 <- kronecker(Diagonal(3, 2:4), t1)) # 15 x 12

## should also work with special-cased logical matrices
13 <- upper.tri(matrix(3,3))
```

ldenseMatrix-class

Description

ldenseMatrix is the virtual class of all dense logical (S4) matrices. It extends both denseMatrix and lMatrix directly.

Slots

x: logical vector containing the entries of the matrix.

Dim, Dimnames: see Matrix.

Extends

Class "lMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "lMatrix". Class "Matrix", by class "denseMatrix".

Methods

coerce signature(from = "matrix", to = "ldenseMatrix"): ...

coerce signature(from = "ldenseMatrix", to = "matrix"): ...

as.vector signature(x = "ldenseMatrix", mode = "missing"): ...

which signature(x = "ndenseMatrix"), semantically equivalent to base function which(x, arr.ind); for details, see the lMatrix class documentation.

See Also

Class lgeMatrix and the other subclasses.

Examples

```r
shwclass("ldenseMatrix")

as(diag(3) > 0, "ldenseMatrix")
```
ldiMatrix-class

Class "ldiMatrix" of Diagonal Logical Matrices

Description

The class "ldiMatrix" of logical diagonal matrices.

Objects from the Class

Objects can be created by calls of the form new("ldiMatrix", ...) but typically rather via Diagonal.

Slots

- `x`: "logical" vector.
- `diag`: "character" string, either "U" or "N", see ddiMatrix.
- `Dim,Dimnames`: matrix dimension and dimnames, see the Matrix class description.

Extends

Class "diagonalMatrix" and class "LMatrix", directly.
Class "sparseMatrix", by class "diagonalMatrix".

See Also

Classes ddiMatrix and diagonalMatrix; function Diagonal.

Examples

```r
(IM <- Diagonal(x = c(TRUE,FALSE,FALSE)))
str(IM)#> gory details (slots)
crossprod(IM) # numeric
(nM <- as(IM, "nMatrix"))# -> sparse (not formally ``diagonal'')
crossprod(nM) # logical sparse
```

lgeMatrix-class

Class "lgeMatrix" of General Dense Logical Matrices

Description

This is the class of general dense logical matrices.

Slots

- `x`: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
- `Dim,Dimnames`: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.
- `factors`: Object of class "list". A named list of factorizations that have been computed for the matrix.
**lsparseMatrix-classes**

**Extends**
Class "ldenseMatrix", directly. Class "lMatrix", by class "ldenseMatrix". Class "denseMatrix", by class "ldenseMatrix". Class "Matrix", by class "ldenseMatrix". Class "Matrix", by class "ldenseMatrix".

**Methods**
Currently, mainly `t()` and coercion methods (for `as(.)`); use, e.g., `showMethods(class="lgeMatrix")` for details.

**See Also**
Non-general logical dense matrix classes such as `ltrMatrix`, or `lsyMatrix`; sparse logical classes such as `lgCMATRIX`.

**Examples**

```r
showClass("lgeMatrix")
str(new("lgeMatrix"))
set.seed(1)
(lM <- Matrix(matrix(rnorm(28), 4,7) > 0)) # a simple random lgeMatrix
set.seed(11)
(lC <- Matrix(matrix(rnorm(28), 4,7) > 0)) # a simple random lgCMATRIX
as(lM, "lgCMATRIX")
```

**lsparseMatrix-classes**  
**Sparse logical matrices**

**Description**

The `lsparseMatrix` class is a virtual class of sparse matrices with TRUE/FALSE entries. Only the positions of the elements that are TRUE are stored. These can be stored in the "triplet" form (classes `lgTMatrix`, `lsTMatrix`, and `ltTMatrix` which really contain pairs, not triplets) or in compressed column-oriented form (classes `lgCMatrix`, `lsCMatrix`, and `ltCMatrix`) or in compressed row-oriented form (classes `lgRMatrix`, `lsRMatrix`, and `ltRMatrix`). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

**Objects from the Class**

Objects can be created by calls of the form `new("lgCMatrix", ...)` and so on. More frequently objects are created by coercion of a numeric sparse matrix to the logical form for use in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence any numeric sparse matrices can be treated as logical sparse matrices.
Slots

- **x**: Object of class "logical", i.e., either TRUE, NA, or FALSE.
- **uplo**: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- **diag**: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when diag is "U". Present in the triangular classes only.
- **p**: Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
- **i**: Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- **j**: Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- **Dim**: Object of class "integer" - the dimensions of the matrix.

Methods

- **coerce** signature(from = "dgCMatrix", to = "lgCMatrix")
- **t** signature(x = "lgCMatrix") returns the transpose of x
- **which** signature(x = "lsparseMatrix"). semantically equivalent to base function which(x, arr.ind); for details, see the lMatrix class documentation.

See Also

the class dgCMatrix

Examples

```r
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
(lm <- (m > 1)) # lgC
!lm # no longer sparse
stopifnot(is(lm,"lsparseMatrix"), identical(!lm, m <- 1))

data(KNex)
str(mmG.1 <- (KNex $ mm) > 0.1)# "lgC..."
table(mmG.1)# however with many "non-structural zeros"
## from logical to nz_pattern -- okay when there are no NA's :
mmG.1 <- as(mmG.1, "nMatrix") # <<< has "TRUE" also where mmG.1 had FALSE
## from logical to "double"
dmG.1 <- as(mmG.1, "dMatrix") # has '0' and back:
lmG.1 <- as(dmG.1, "lMatrix") # has no extra FALSE, i.e. drop0() included
stopifnot(identical(mmG.1, as((KNex $ mm) != 0,"nMatrix")),
validObject(lmG.1), all(lmG.1@x),
# same "logical" but lmG.1 has no 'FALSE' in x slot:
all(lmG.1 == mmG.1))

class(xnx <- crossprod(mmG.1))# "nsC..."
class(xlx <- crossprod(mmG.1))# "dsC..." : numeric
```
is0 <- (xlx == 0)
mean(as.vector(is0)) # 99.3% zeros: quite sparse, but
table(xlx*is0 == 0) # more than half of the entries are (non-structural!) 0
stopifnot(isSymmetric(xlx), isSymmetric(xnx),
  # compare xnx and xlx: have the *same* non-structural 0s :
sapply(slotNames(xnx),
  function(n) identical(slot(xnx, n), slot(xlx, n))))

lsyMatrix-class

Symmetric Dense Logical Matrices

Description

The "lsyMatrix" class is the class of symmetric, dense logical matrices in non-packed storage and
"lspMatrix" is the class of these in packed storage. In the packed form, only the upper triangle
or the lower triangle is stored.

Objects from the Class

Objects can be created by calls of the form new("lsyMatrix", ...).

Slots

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower
triangular.

x: Object of class "logical". The logical values that constitute the matrix, stored in column-major
order.

Dim,Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the
Matrix class.

factors: Object of class "list". A named list of factorizations that have been computed for the
matrix.

Extends

Both extend classes "ldenseMatrix" and "symmetricMatrix", directly; further, class "Matrix"
and others, indirectly. Use showClass("lsyMatrix"), e.g., for details.

Methods

Currently, mainly t() and coercion methods (for as(.): use, e.g.,
showMethods(class="dsyMatrix") for details.

See Also

lgematrix, Matrix, t

Examples

(M2 <- Matrix(c(TRUE, NA,FALSE,FALSE), 2,2)) # logical dense (ltr)
str(M2)
# can
(sM <- M2 | t(M2)) # "lgem"n
as(sM, "lsyMatrix"))
str(sM <- as(sM, "lspMatrix")) # packed symmetric

IsyMatrix-class
**ltrMatrix-class**

**Triangular Dense Logical Matrices**

**Description**

The "ltrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ltrpMatrix" class is the same except in packed storage.

**Slots**

- **x**: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
- **uplo**: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- **diag**: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see `triangularMatrix`.

**Dim,Dimnames**: The dimension (a length-2 "integer") and corresponding names (or NULL), see the `Matrix` class.

**factors**: Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

Both extend classes "ldenseMatrix" and "triangularMatrix", directly; further, class "Matrix", "lMatrix" and others, indirectly. Use `showClass("ltrMatrix")`, e.g., for details.

**Methods**

Currently, mainly `t()` and coercion methods (for `as()`); use, e.g., `showMethods(class="ltrMatrix")` for details.

**See Also**

Classes `lgeMatrix, Matrix`; function `t`

**Examples**

```r
showClass("ltrMatrix")

str(new("ltrpMatrix"))
(lutr <- as(upper.tri(matrix(,4,4)), "ltrMatrix"))
str(ltp <- as(lutr, "ltrpMatrix")) # packed matrix: only 10 = (4+1)*4/2 entries
!ltp # the logical negation (is *not* logical triangular !)
## but this one is:
stopifnot(all.equal(ltp, as(!ltp, "ltrpMatrix")))
```
(Generalized) Triangular Decomposition of a Matrix

Description

Computes (generalized) triangular decompositions of square (sparse or dense) and non-square dense matrices.

Usage

```r
lu(x, ...)  
## S4 method for signature 'matrix'
lu(x, warnSing = TRUE, ...)  
## S4 method for signature 'dgeMatrix'
lu(x, warnSing = TRUE, ...)  
## S4 method for signature 'dgCMatrix'
lu(x, errSing = TRUE, order = TRUE, tol = 1, ...)
```

Arguments

- `x` a dense or sparse matrix, in the latter case of square dimension. No missing values or IEEE special values are allowed.
- `warnSing` (when `x` is a "denseMatrix") logical specifying if a warning should be signalled when `x` is singular.
- `errSing` (when `x` is a "sparseMatrix") logical specifying if an error (see `stop`) should be signalled when `x` is singular. When `x` is singular, `lu(x, errSing=FALSE)` returns NA instead of an LU decomposition. No warning is signalled and the user should be careful in that case.
- `order` logical or integer, used to choose which fill-reducing permutation technique will be used internally. Do not change unless you know what you are doing.
- `tol` positive number indicating the pivoting tolerance used in `cs_1u`. Do only change with much care.
- `...` further arguments passed to or from other methods.

Details

`lu()` is a generic function with special methods for different types of matrices. Use `showMethods("lu")` to list all the methods for the `lu` generic.

The method for class `dgeMatrix` (and all dense matrices) is based on LAPACK's "dgetrf" subroutine. It returns a decomposition also for singular and non-square matrices.

The method for class `dgCMatrix` (and all sparse matrices) is based on functions from the CSparse library. It signals an error (or returns NA, when `errSing = FALSE`, see above) when the decomposition algorithm fails, as when `x` is (too close to) singular.

Value

An object of class "LU", i.e., "denseLU" (see its separate help page), or "sparseLU", see `sparseLU`; this is a representation of a triangular decomposition of `x`. 
**LU-class**

**References**

Tim Davis (2005) [http://www.cise.ufl.edu/research/sparse/CSparse/](http://www.cise.ufl.edu/research/sparse/CSparse/)

**See Also**

Class definitions `LU` and `sparseLU` and function `expand; qr, chol`.

**Examples**

```r
### Dense
x <- Matrix(rnorm(9), 3, 3)
lx <- lu(x)
dim(lx) <- round(10 * x[,3]) # non-square
expand(lx) <- lu(lx)

### Sparse
pm <- as(readMM(system.file("external/pores.1.mtx",
   package = "Matrix")),
   "CsparseMatrix")
str(pmLU <- lu(pm)) # p is a 0-based permutation of the rows
   # q is a 0-based permutation of the columns
## permute rows and columns of original matrix
pLU <- pm[pmLU@p + 1L, pmLU@q + 1L] # L \times U \rightarrow dropping extra zeros
## equal up to "rounding"
ppm[1:14, 1:5]
pLU[1:14, 1:5]
```

---

**LU-class**

**LU (dense) Matrix Decompositions**

**Description**

The "LU" class is the virtual class of LU decompositions of real matrices. "denseLU" the class of LU decompositions of dense real matrices.

**Details**

The decomposition is of the form

\[ A = PLU \]

where typically all matrices are of size \( n \times n \), and the matrix \( P \) is a permutation matrix, \( L \) is lower triangular and \( U \) is upper triangular (both of class `dtrMatrix`).

Note that the dense decomposition is also implemented for a \( m \times n \) matrix \( A \), when \( m \neq n \).

If \( m < n \) ("wide case"), \( U \) is \( m \times n \), and hence not triangular.

If \( m > n \) ("long case"), \( L \) is \( m \times n \), and hence not triangular.
Objects from the Class

Objects can be created by calls of the form `new("denseLU", ...`). More commonly the objects are created explicitly from calls of the form `lu(mm)` where `mm` is an object that inherits from the "dgeMatrix" class or as a side-effect of other functions applied to "dgeMatrix" objects.

Extends

"LU" directly extends the virtual class "MatrixFactorization".
"denseLU" directly extends "LU".

Slots

- `x`: object of class "numeric". The "L" (unit lower triangular) and "U" (upper triangular) factors of the original matrix. These are stored in a packed format described in the Lapack manual, and can retrieved by the `expand()` method, see below.
- `perm`: Object of class "integer" - a vector of length `min(dim)` that describes the permutation applied to the rows of the original matrix. The contents of this vector are described in the Lapack manual.
- `dim`: the dimension of the original matrix; inherited from class `MatrixFactorization`.

Methods

- `expand` signature(x = "denseLU"): Produce the "L" and "U" (and "P") factors as a named list of matrices, see also the example below.
- `solve` signature(a = "denseLU", b = "missing"): Compute the inverse of A, A⁻¹. `solve(A)` using the LU decomposition, see also `solve-methods`.

See Also

class `sparseLU` for LU decompositions of sparse matrices; further, class `dgeMatrix` and functions `lu`, `expand`.

Examples

```r
set.seed(1)
mm <- Matrix(round(rnorm(9),2), nrow = 3)
mm
mm
str(lum <- lu(mm))
elu <- expand(lum)
eelu # three components: "L", "U", and "P", the permutation
eelu$L %*% elu$U
(m2 <- with(eelu, P %*% L %*% U)) # the same as 'mm'
stopifnot(all.equal(as(mm, "matrix"),
                   as(m2, "matrix")))
```
Construct a Classed Matrix

Description

Construct a Matrix of a class that inherits from Matrix.

Usage

Matrix(data = NA, nrow = 1, ncol = 1, byrow = FALSE, dimnames = NULL,
       sparse = NULL, doDiag = TRUE, forceCheck = FALSE)

Arguments

data an optional numeric data vector or matrix.
nrow when data is not a matrix, the desired number of rows
ncol when data is not a matrix, the desired number of columns
byrow logical. If FALSE (the default) the matrix is filled by columns, otherwise the
       matrix is filled by rows.
dimnames a dimnames attribute for the matrix: a list of two character components. They
       are set if not NULL (as per default).
sparse logical or NULL, specifying if the result should be sparse or not. By default, it is
       made sparse when more than half of the entries are 0.
       Note that when the resulting matrix is diagonal ("mathematically"), sparse=FALSE
       results in a diagonalMatrix, unless doDiag=FALSE as well, see the first examples.
doDiag only when sparse = FALSE, logical indicating if a diagonalMatrix object
       should be considered (default). Otherwise, in such a case, a dense (symmetric)
       matrix will be returned.
forceCheck logical indicating if the checks for structure should even happen when data is
       already a "Matrix" object.

Details

If either of nrow or ncol is not given, an attempt is made to infer it from the length of data and the
other parameter. Further, Matrix() makes efforts to keep logical matrices logical, i.e., inheriting
from class Matrix, and to determine specially structured matrices such as symmetric, triangular
or diagonal ones. Note that a symmetric matrix also needs symmetric dimnames, e.g., by specifying
dimnames = list(NULL, NULL), see the examples.

Most of the time, the function works via a traditional (full) matrix. However,
Matrix(0, nrow, ncol) directly constructs an "empty" sparseMatrix, as does Matrix(FALSE, *).
Although it is sometime possible to mix unclassed matrices (created with matrix) with ones of
class "Matrix", it is much safer to always use carefully constructed ones of class "Matrix".

Value

Returns matrix of a class that inherits from "Matrix". Only if data is not a matrix and does not
already inherit from class Matrix are the arguments nrow, ncol and byrow made use of.
Matrix-class

See Also

The classes Matrix, symmetricMatrix, triangularMatrix, and diagonalMatrix; further, matrix.

Special matrices can be constructed, e.g., via sparseMatrix (sparse), bdiag (block-diagonal), bandSparse (banded sparse), or Diagonal.

Examples

Matrix(0, 3, 2)  # 3 by 2 matrix of zeros -> sparse
Matrix(0, 3, 2, sparse=FALSE)# -> 'dense'
Matrix(0, 2, 2, sparse=FALSE)# diagonal !
Matrix(0, 2, 2, sparse=FALSE, doDiag=FALSE)# -> dense
Matrix(1:6, 3, 2)  # a 3 by 2 matrix (+ integer warning)
Matrix(1:6 + 1, nrow=3)

## logical ones:

   is(Matrix(FALSE, 1,1), "sparseMatrix"))

Matrix-class

Virtual Class "Matrix" Class of Matrices

Description

The Matrix class is a class contained by all actual classes in the Matrix package. It is a "virtual" class.

Slots

Common to all matrix objects in the package:

Dim: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

Dimnames: list of length two; each component containing NULL or a character vector length equal the corresponding Dim element.
Matrix-class

Methods

determinant signature(x = "Matrix", logarithm = "missing"): and
determinant signature(x = "Matrix", logarithm = "logical"): compute the (log) determinant of x. The method chosen depends on the actual Matrix class of x. Note that det also works for all our matrices, calling the appropriate determinant() method. The Matrix::det is an exact copy of base:::det, but in the correct namespace, and hence calling the S4-aware version of determinant().

diff signature(x = "Matrix"): As diff() for traditional matrices, i.e., applying diff() to each column.

dim signature(x = "Matrix"): extract matrix dimensions dim.

dim<- signature(x = "Matrix", value = "ANY"): where value is integer of length 2. Allows to reshape Matrix objects, but only when prod(value) == prod(dim(x)).

dimnames signature(x = "Matrix"): extract dimnames.

dimnames<- signature(x = "Matrix", value = "list"): set the dimnames to a list of length 2, see dimnames<-.

length signature(x = "Matrix"): simply defined as prod(dim(x)) (and hence of mode "double").

show signature(object = "Matrix"): show method for printing.

image signature(object = "Matrix"): draws an image of the matrix entries, using levelplot() from package lattice.

head signature(object = "Matrix"): return only the “head”, i.e., the first few rows.

tail signature(object = "Matrix"): return only the “tail”, i.e., the last few rows of the respective matrix.

as.matrix, as.array signature(x = "Matrix"): the same as as(x, "matrix"); see also the note below.

as.vector signature(x = "Matrix", mode = "missing"): as.vector(m) should be identical to as.vector(as(m,"matrix")), implemented more efficiently for some subclasses.

as(x, "vector"), as(x, "numeric") etc, similarly.

There are many more methods that (conceptually should) work for all "Matrix" objects, e.g., colSums, rowMeans. Even base functions may work automagically (if they first call as.matrix() on their principal argument), e.g., apply, eigen, svd or kappa all do work via coercion to a “traditional” (dense) matrix.

Note

Loading the Matrix namespace “overloads” as.matrix and as.array in the base namespace by the equivalent of function(x) as(x, "matrix"). Consequently, as.matrix(m) or as.array(m) will properly work when m inherits from the "Matrix" class — also for functions in package base and other packages. E.g., apply or outer can therefore be applied to "Matrix" matrices.

Author(s)

Douglas Bates <bates@stat.wisc.edu> and Martin Maechler

See Also

colSums, rowMeans. Even base functions may work automagically (if they first call as.matrix() on their principal argument), e.g., apply, eigen, svd or kappa all do work via coercion to a “traditional” (dense) matrix.

Methods, e.g., for kronecker.
Examples

```r
slotNames("Matrix")

c1 <- getClass("Matrix")
names(cl@subclasses) # more than 40 .

showClass("Matrix")## output with slots and all subclasses

(M <- Matrix(c(0,1,0,0), 6, 4))
dim(M)
diag(M)
cm <- M[1:4,] + 10*Diagonal(4)
diff(M)
## can reshape it even :
dim(M) <- c(2, 12)
M
stopifnot(identical(M, Matrix(c(0,1,0,0), 2,12)),
  all.equal(det(cm),
    determinant(as(cm,"matrix"), log=FALSE)$modulus,
    check.attributes=FALSE))
```

Description

The basic matrix product, %*% is implemented for all our `Matrix` and also for `sparseVector` classes, fully analogously to `R`’s base `matrix` and `vector` objects.

The functions `crossprod` and `tcrossprod` are matrix products or “cross products”, ideally implemented efficiently without computing `t(.)`’s unnecessarily. They also return `symmetricMatrix` classed matrices when easily detectable, e.g., in `crossprod(m)`, the one argument case.

tcrossprod() takes the cross-product of the transpose of a matrix. tcrossprod(x) is formally equivalent to, but faster than, the call `x %*% t(x)`, and so is tcrossprod(x, y) instead of `x %*% t(y)`.

Usage

```r
## S4 method for signature 'CsparseMatrix,diagonalMatrix'
x %*% y
  ## .... and many more

## S4 method for signature 'dgeMatrix,missing'
crossprod(x, y = NULL)
  ## .... and many more

## S4 method for signature 'CsparseMatrix,ddenseMatrix'
tcrossprod(x, y = NULL)
  ## .... and many more
```
matrix-products

Arguments

- **x**: a matrix-like object
- **y**: a matrix-like object, or for \([t\)crossprod() \} NULL (by default); the latter case is formally equivalent to \(y = x\).

Details

For some classes in the Matrix package, such as `dgCMatrix`, it is much faster to calculate the cross-product of the transpose directly instead of calculating the transpose first and then its cross-product.

Value

A `Matrix` object, in the one argument case of an appropriate symmetric matrix class.

Methods

- \(%*%\) signature(x = "dgeMatrix", y = "dgeMatrix"): Matrix multiplication; ditto for several other signature combinations, see `showMethods("%*%", class = "dgeMatrix")`.
- \(%*%\) signature(x = "dtrMatrix", y = "matrix") and other signatures (use `showMethods("%*%", class="dtrMatrix")`): matrix multiplication. Multiplication of (matching) triangular matrices now should remain triangular (in the sense of class `triangularMatrix`).
- `crossprod` signature(x = "dgeMatrix", y = "dgeMatrix"): ditto for several other signatures, use `showMethods("crossprod", class = "dgeMatrix"), matrix crossproduct, an efficient version of \(t(x) \%*% y\).
- `crossprod` signature(x = "CsparseMatrix", y = "missing") returns \(t(x) \%*% x\) as an `dsCMatrix` object.
- `crossprod` signature(x = "TsparseMatrix", y = "missing") returns \(t(x) \%*% x\) as an `dsCMatrix` object.
- `crossprod,tcrossprod` signature(x = "dtrMatrix", y = "matrix") and other signatures, see “\%*%” above.

See Also

- `tcrossprod` in R’s base, `crossprod` and `\%*\`.

Examples

```r
## A random sparse "incidence" matrix:
m <- matrix(0, 400, 500)
set.seed(12)
m[runif(314, 0, length(m))] <- 1
mm <- as(m, "dgCMatrix")
object.size(m) / object.size(mm) # smaller by a factor of > 200

## tcrossprod() is very fast:
system.time(tCmm <- tcrossprod(mm)) # 0 (PIII, 933 MHz)
system.time(cm <- crossprod(t(m))) # 0.16
system.time(cm <- tcrossprod(m)) # 0.02

stopifnot(cm == as(tCmm, "matrix"))
```
MatrixFactorization-class

Class "MatrixFactorization" of Matrix Factorizations

Description

The class "MatrixFactorization" is the virtual (super) class of (potentially) all matrix factorizations of matrices from package Matrix.

The class "CholeskyFactorization" is the virtual class of all Cholesky decompositions from Matrix (and trivial sub class of "MatrixFactorization").

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

```language=r
Dim: Object of class "integer" - the dimensions of the original matrix - must be an integer vector with exactly two non-negative values.
```  
Methods

```language=r
dim (x) simply returns x@dim, see above.

eexpand signature(x = "MatrixFactorization"): this has not been implemented yet for all matrix factorizations. It should return a list whose components are matrices which when multiplied return the original Matrix object.

show signature(object = "MatrixFactorization"): simple printing, see show.

solve signature(a = "MatrixFactorization", b = .): solve $Ax = b$ for $x$; see solve-methods.
```

See Also

classes inheriting from "MatrixFactorization", such as LU, Cholesky, CHMfactor, and sparseQR.

Examples

```language=r
showClass("MatrixFactorization")
getClass("CholeskyFactorization")
```
**ndenseMatrix-class**

**Virtual Class "ndenseMatrix" of Dense Logical Matrices**

**Description**

`ndenseMatrix` is the virtual class of all dense logical (S4) matrices. It extends both `denseMatrix` and `lMatrix` directly.

**Slots**

- `x`: logical vector containing the entries of the matrix.
- `Dim`, `Dimnames`: see `Matrix`.

**Extends**

Class "mMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "mMatrix". Class "Matrix", by class "denseMatrix".

**Methods**

- `%*%` signature(x = "n sparseMatrix", y = "ndenseMatrix"): ...
- `%*%` signature(x = "ndenseMatrix", y = "n sparseMatrix"): ...
- `coerce` signature(from = "matrix", to = "ndenseMatrix"): ...
- `coerce` signature(from = "ndenseMatrix", to = "matrix"): ...
- `crossprod` signature(x = "n sparseMatrix", y = "ndenseMatrix"): ...
- `crossprod` signature(x = "ndenseMatrix", y = "n sparseMatrix"): ...
- `as.vector` signature(x = "ndenseMatrix", mode = "missing"): ...
- `diag` signature(x = "ndenseMatrix"): extracts the diagonal as for all matrices, see the generic `diag()`.
- `which` signature(x = "ndenseMatrix"), semantically equivalent to base function `which(x, arr.ind);` for details, see the `lMatrix` class documentation.

**See Also**

Class `ngeMatrix` and the other subclasses.

**Examples**

```r
showClass("ndenseMatrix")

as(diag(3) > 0, "ndenseMatrix")# -> "nge"
```
nearPD

Nearest Positive Definite Matrix

Description

Compute the nearest positive definite matrix to an approximate one, typically a correlation or variance-covariance matrix.

Usage

nearPD(x, corr = FALSE, keepDiag = FALSE, do2eigen = TRUE,
        doSym = FALSE, doDykstra = TRUE, only.values = FALSE,
        ensureSymmetry = !isSymmetric(x),
        eig.tol = 1e-06, conv.tol = 1e-07, posd.tol = 1e-08,
        maxit = 100, conv.norm.type = "I", trace = FALSE)

Arguments

- **x**: numeric \( n \times n \) approximately positive definite matrix, typically an approximation to a correlation or covariance matrix. If \( x \) is not symmetric (and ensureSymmetry is not false), \( \text{symmpart}(x) \) is used.
- **corr**: logical indicating if the matrix should be a correlation matrix.
- **keepDiag**: logical, generalizing **corr**: if \( \text{TRUE} \), the resulting matrix should have the same diagonal (\( \text{diag}(x) \)) as the input matrix.
- **do2eigen**: logical indicating if a \text{posdefify()} eigen step should be applied to the result of the Higham algorithm.
- **doSym**: logical indicating if \( X \leftarrow (X + t(X))/2 \) should be done, after \( X \leftarrow \text{tcrossprod}(Qd, Q) \); some doubt if this is necessary.
- **doDykstra**: logical indicating if Dykstra’s correction should be used; true by default. If false, the algorithm is basically the direct fixpoint iteration \( Y_k = P_U(P_S(Y_{k-1})) \).
- **only.values**: logical; if \( \text{TRUE} \), the result is just the vector of eigen values of the approximating matrix.
- **ensureSymmetry**: logical; by default, \( \text{symmpart}(x) \) is used whenever \( \text{isSymmetric}(x) \) is not true. The user can explicitly set this to \( \text{TRUE} \) or \( \text{FALSE} \), saving the symmetry test. \text{Beware} however that setting it \( \text{FALSE} \) for an asymmetric input \( x \), is typically nonsense!
- **eig.tol**: defines relative positiveness of eigenvalues compared to largest one, \( \lambda_1 \). Eigen values \( \lambda_k \) are treated as if zero when \( \lambda_k/\lambda_1 \leq \text{eig.tol} \).
- **conv.tol**: convergence tolerance for Higham algorithm.
- **posd.tol**: tolerance for enforcing positive definiteness (in the final posdefify step when do2eigen is \text{TRUE}).
- **maxit**: maximum number of iterations allowed.
- **conv.norm.type**: convergence norm type (\text{norm(*, type)}) used for Higham algorithm. The default is "I" (infinity), for reasons of speed (and back compatibility); using "F" is more in line with Higham’s proposal.
- **trace**: logical or integer specifying if convergence monitoring should be traced.
nearPD

Details
This implements the algorithm of Higham (2002), and then (if do2eigen is true) forces positive definiteness using code from posdefify. The algorithm of Knol DL and ten Berge (1989) (not implemented here) is more general in (1) that it allows constraints to fix some rows (and columns) of the matrix and (2) to force the smallest eigenvalue to have a certain value.

Note that setting corr = TRUE just sets diag(.) <- 1 within the algorithm.

Higham (2002) uses Dykstra’s correction, but the version by Jens Oehlschlaegel did not use it (accidentally), and has still lead to good results; this simplification, now only via doDykstra = FALSE, was active in nearPD() up to Matrix version 0.999375-40.

Value
If only.values = TRUE, a numeric vector of eigen values of the approximating matrix; Otherwise, as by default, an S3 object of class "nearPD", basically a list with components

mat a matrix of class dpomat, the computed positive-definite matrix.
eigenvalues numeric vector of eigen values of mat.
corr logical, just the argument corr.
normF the Frobenius norm (norm(x-X, "F")) of the difference between the original and the resulting matrix.
iterations number of iterations needed.
converged logical indicating if iterations converged.

Author(s)
Jens Oehlschlaegel donated a first version. Subsequent changes by the Matrix package authors.

References

See Also
A first version of this (with non-optional corr=TRUE) has been available as nearcor(); and more simple versions with a similar purpose posdefify(), both from package sfsmisc.

Examples
```r
## Higham(2002), p.334f - simple example
A <- matrix(1, 3, 3); A[1,3] <- A[3,1] <- 0
n.A <- nearPD(A, corr=TRUE, do2eigen=FALSE)
n.A[c("mat","normF")]
stopifnot(all.equal(n.A$mat[1,2], 0.760689917),
         all.equal(n.A$normF, 0.52779033, tolerance=1e-9))

set.seed(27)
```
m <- matrix(round(rnorm(25),2), 5, 5)
m <- m + t(m)
diag(m) <- pmax(0, diag(m)) + 1
(m <- round(cov2cor(m), 2))

str(near.m <- nearPD(m, trace = TRUE))
round(near.m$mat, 2)
norm(m - near.m$mat) # 1.102 / 1.08

if(require("sfsmisc")) {
m2 <- posdefify(m) # a simpler approach
norm(m - m2) # 1.185, i.e., slightly "less near"
}

round(nearPD(m, only.values=TRUE), 9)

## A longer example, extended from Jens' original,
## showing the effects of some of the options:

pr <- Matrix(c(1, 0.477, 0.644, 0.478, 0.651, 0.826,
               0.477, 1, 0.516, 0.233, 0.682, 0.75,
               0.644, 0.516, 1, 0.599, 0.581, 0.742,
               0.478, 0.233, 0.599, 1, 0.741, 0.8,
               0.651, 0.682, 0.581, 0.741, 1, 0.798,
               0.826, 0.75, 0.742, 0.8, 0.798, 1),
nrow = 6, ncol = 6)

nc. <- nearPD(pr, conv.tol = 1e-7) # default
nc.$iterations # 2
nc.1 <- nearPD(pr, conv.tol = 1e-7, corr = TRUE)
nc.1$iterations # 11 / 12 (!)
ncr <- nearPD(pr, conv.tol = 1e-15)
str(ncr)# still 2 iterations
ncr.1 <- nearPD(pr, conv.tol = 1e-15, corr = TRUE)
ncr.1 $ iterations # 27 / 30 !

ncF <- nearPD(pr, conv.tol = 1e-15, conv.norm = "F")
stopifnot(all.equal(ncr, ncF))# norm type does not matter at all in this example

## But indeed, the 'corr = TRUE' constraint did ensure a better solution;
## cov2cor() does not just fix it up equivalently:
norm(pr - cov2cor(ncr$mat)) # = 0.89994
norm(pr - ncr.1$mat) # = 0.08746 / 0.08805

### 3) a real data example from a 'systemfit' model (3 eq.):
(load(system.file("external", "symW.rda", package="Matrix"))) # "symW"
dim(symW) # 24 x 24
class(symW)# "dsCMatrix": sparse symmetric
if(dev.interactive()) image(symW)
EV <- eigen(symW, only=TRUE)$values
summary(EV) # looking more closely (EV sorted decreasingly):
tail(EV)# all 6 are negative
EV2 <- eigen(sWpos <- nearPD(symW)$mat, only=TRUE)$values
stopifnot(EV2 > 0)
if(require("sfsmisc")) {
  plot(pmax(1e-3,EV), EV2, type="o", log="xy", xaxt="n",yaxt="n")
eaxis(1); eaxis(2)
ngeMatrix-class

Class "ngeMatrix" of General Dense Nonzero-pattern Matrices

Description

This is the class of general dense nonzero-pattern matrices, see nMatrix.

Slots

x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

Dim, Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.

factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

Class "ndenseMatrix", directly. Class "lMatrix", by class "ndenseMatrix". Class "denseMatrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix".

Methods

Currently, mainly t() and coercion methods (for as(.)); use, e.g., showMethods(class="ngeMatrix") for details.

See Also

Non-general logical dense matrix classes such as ntrMatrix, or nsyMatrix; sparse logical classes such as ngCMatrix.

Examples

showClass("ngeMatrix")
## "lgeMatrix" is really more relevant
Class "nMatrix" of Non-zero Pattern Matrices

Description

The nMatrix class is the virtual "mother" class of all non-zero pattern (or simply pattern) matrices in the Matrix package.

Slots

Common to all matrix object in the package:

- **Dim**: Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.
- **Dimnames**: list of length two; each component containing NULL or a character vector length equal the corresponding Dim element.

Methods

There is a bunch of coercion methods (for as(.)), e.g.,

- **coerce** signature(from = "nMatrix", to = "matrix"): ...
- **coerce** signature(from = "nMatrix", to = "dMatrix"): ...
- **coerce** signature(from = "nMatrix", to = "lMatrix"): ...
- **coerce** signature(from = "matrix", to = "nMatrix"): Note that these coercions (must) coerce NAs to non-zero, hence conceptually TRUE. This is particularly important when sparseMatrix objects are coerced to "nMatrix" and hence to nsparseMatrix.
- **coerce** signature(from = "dMatrix", to = "nMatrix"): ...
- **coerce** signature(from = "lMatrix", to = "nMatrix"): ...

. Additional methods contain group methods, such as

- **Ops** signature(e1 = "nMatrix", e2 = "....."): ....
- **Arith** signature(e1 = "nMatrix", e2 = "....."): ....
- **Compare** signature(e1 = "nMatrix", e2 = "....."): ....
- **Logic** signature(e1 = "nMatrix", e2 = "....."): ....
- **Summary** signature(x = "nMatrix", "....."): ....

See Also

The classes lMatrix, nsparseMatrix, and the mother class, Matrix.

Examples

gtclass("nMatrix")

L3 <- Matrix(upper.tri(diag(3)))
L3 # an "ltCMatrix"
as(L3, "nMatrix") # -> ntc*

## similar, not using Matrix()
as(upper.tri(diag(3)), "nMatrix")# currently "ngTMatrix"
nnzero

The Number of Non-Zero Values of a Matrix

Description

Returns the number of non-zero values of a numeric-like R object, and in particular an object x inheriting from class Matrix.

Usage

nnzero(x, na.counted = NA)

Arguments

x

an R object, typically inheriting from class Matrix or numeric.

na.counted

a logical describing how NAs should be counted. There are three possible settings for na.counted:

TRUE  NAs are counted as non-zero (since “they are not zero”).

NA   (default) the result will be NA if there are NA’s in x (since “NA’s are not known, i.e., may be zero”).

FALSE  NAs are omitted from x before the non-zero entries are counted.

For sparse matrices, you may often want to use na.counted = TRUE.

Value

the number of non zero entries in x (typically integer).

Note that for a symmetric sparse matrix S (i.e., inheriting from class symmetricMatrix), nnzero(S) is typically twice the length(S@x).

Methods

signature(x = "ANY") the default method for non-Matrix class objects, simply counts the number of non-zero entries in x, counting NA’s depending on the na.counted argument, see above.

signature(x = "denseMatrix") conceptually the same as for traditional matrix objects, care has to be taken for symmetricMatrix objects.

signature(x = "diagonalMatrix"), and signature(x = "indMatrix") fast simple methods for these special sparseMatrix classes.

signature(x = "sparseMatrix") typically, the most interesting method, also carefully taking into account.

See Also

The Matrix class also has a length method; typically, length(M) is much larger than nnzero(M) for a sparse matrix M, and the latter is a better indication of the size of M.
Examples

```r
m <- Matrix(0+1:28, nrow = 4)
m[-3, c(2,4:5,7)] <- m[ 3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "dgTMatrix"))
nzzero(mT)
(S <- crossprod(mT))
nzzero(S)
str(S) # slots are smaller than nzzero()
stopifnot(nzzero(S) == sum(as.matrix(S) != 0))# failed earlier
data(KNex)
M <- KNex$mm
class(M)
dim(M)
length(M); stopifnot(length(M) == prod(dim(M)))
nzzero(M) # more relevant than length
## the above are also visible from
str(M)
```

---

### norm

#### Matrix Norms

**Description**

Computes a matrix norm of \( x \), using Lapack for dense matrices. The norm can be the one norm, the infinity norm, the Frobenius norm, or the maximum modulus among elements of a matrix, as determined by the value of type.

**Usage**

`norm(x, type, ...)`

**Arguments**

- **x**  
a real or complex matrix.
- **type**  
A character indicating the type of norm desired.  
"0", "o" or "1" specifies the one norm, (maximum absolute column sum);  
"I" or "i" specifies the infinity norm (maximum absolute row sum);  
"F" or "f" specifies the Frobenius norm (the Euclidean norm of \( x \) treated as if it were a vector); and  
"M" or "m" specifies the maximum modulus of all the elements in \( x \).  
The default is "0". Only the first character of type[1] is used.
- **...**  
further arguments passed to or from other methods.

**Details**

For dense matrices, the methods eventually call the Lapack functions dланге, dlanзy, dланtr, zланге, zланзy, and zланtr.

**Value**

A numeric value of class "norm", representing the quantity chosen according to type.
References

See Also

onenormest(), an approximate randomized estimate of the 1-norm condition number, efficient for large sparse matrices.

Examples

```r
x <- Hilbert(9)
norm(x, "1")
norm(x, "I")
norm(x, "F")
norm(x, "M")
```

Description

The `nsparseMatrix` class is a virtual class of sparse "pattern" matrices, i.e., binary matrices conceptually with TRUE/FALSE entries. Only the positions of the elements that are TRUE are stored. These can be stored in the "triplet" form (classes `ngTMatrix`, `nsTMatrix`, and `ntTMatrix` which really contain pairs, not triplets) or in compressed column-oriented form (classes `ngCMatrix`, `nsCMatrix`, and `ntCMatrix`) or in compressed row-oriented form (classes `ngRMatrix`, `nsRMatrix`, and `ntRMatrix`). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

Objects from the Class

Objects can be created by calls of the form `new("ngCMatrix", ...)` and so on. More frequently objects are created by coercion of a numeric sparse matrix to the pattern form for use in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence numeric sparse matrices can be treated as sparse pattern matrices.

Slots

- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- `diag`: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when `diag` is "U". Present in the triangular classes only.
- `p`: Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
i: Object of class "integer" of length nnzero (number of non-zero elements). These are the row
numbers for each TRUE element in the matrix. All other elements are FALSE. Present in
triplet and compressed column-oriented forms only.

j: Object of class "integer" of length nnzero (number of non-zero elements). These are the
column numbers for each TRUE element in the matrix. All other elements are FALSE. Present
in triplet and compressed column-oriented forms only.

Dim: Object of class "integer" - the dimensions of the matrix.

Methods

coerce signature(from = "dgCMatrix", to = "ngCMatrix"), and many similar ones; typically
you should coerce to "nsparseMatrix" (or "nMatrix"). Note that coercion to a sparse pattern
matrix records all the potential non-zero entries, i.e., explicit ("non-structural") zeroes are
coeersed to TRUE, not FALSE, see the example.

t signature(x = "ngCMatrix"): returns the transpose of x

which signature(x = "lsparseMatrix"), semantically equivalent to base function

nsyMatrix-class Symmetric Dense Nonzero-Pattern Matrices

Description

The "nsyMatrix" class is the class of symmetric, dense nonzero-pattern matrices in non-packed
storage and "nspMatrix" is the class of of these in packed storage. Only the upper triangle or the
lower triangle is stored.
Objects from the Class

Objects can be created by calls of the form `new("nsyMatrix", ...)`.

Slots

- `uplo`: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- `x`: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
- `Dim,Dimnames`: The dimension (a length-2 "integer") and corresponding names (or NULL), see the `Matrix` class.
- `factors`: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

"nsyMatrix" extends class "ngeMatrix", directly, whereas "nspMatrix" extends class "ndenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, indirectly, use `showClass("nsyMatrix")`, e.g., for details.

Methods

Currently, mainly `t()` and coercion methods (for `as()`); use, e.g., `showMethods(class="dsyMatrix")` for details.

See Also

`ngeMatrix`, `Matrix`, `t`

Examples

```r
(s0 <- new("nsyMatrix"))
(M2 <- Matrix(c(TRUE, NA, FALSE, FALSE), 2, 2)) # logical dense (ltr)
(sM <- M2 & t(M2)) # "ltre"
class(sM <- as(sM, "nMatrix")) # -> "nge"  
(sM <- as(sM, "nsyMatrix")) # -> "nsy"  
str(sM <- as(sM, "nspMatrix")) # -> "nsp": packed symmetric
```

Description

The "ntnMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ntpMatrix" class is the same except in packed storage.
Slots

x: Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

uplo: Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

diag: Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see triangularMatrix.

Dim,Dimnames: The dimension (a length-2 "integer") and corresponding names (or NULL), see the Matrix class.

factors: Object of class "list". A named list of factorizations that have been computed for the matrix.

Extends

"nttrMatrix" extends class "ngeMatrix", directly, whereas "ntpmMatrix" extends class "ndenseMatrix", directly.

Both extend Class "triangularMatrix", directly, and class "denseMatrix", "lMatrix" and others, indirectly, use showClass("nsyMatrix"), e.g., for details.

Methods

Currently, mainly t() and coercion methods (for as()); use, e.g., showMethods(class="nsyMatrix") for details.

See Also

Classes ngeMatrix, Matrix; function t

Examples

showClass("nttrMatrix")

str(new("nttpMatrix"))
(nutr <- as.upper.tri(matrix(c(4,4)), "nttrMatrix"))
str(nutp <- as(nutr, "ntpmMatrix"))# packed matrix: only 10 = (4+1)*4/2 entries
!nutp ## the logical negation (is *not* logical triangular !)
## but this one is:
stopifnot(all.equal(nutp, as(!nutp, "nttpMatrix")))

number-class

Class “number” of Possibly Complex Numbers

Description

The class "number" is a virtual class, currently used for vectors of eigen values which can be "numeric" or "complex".

It is a simple class union (setClassUnion) of "numeric" and "complex".

Objects from the Class

Since it is a virtual Class, no objects may be created from it.
Examples

```r
showClass("number")
stopifnot( is(li, "number"), is(pi, "number"), is(1:3, "number") )
```

---

**Description**

The "pMatrix" class is the class of permutation matrices, stored as 1-based integer permutation vectors.

Matrix (vector) multiplication with permutation matrices is equivalent to row or column permutation, and is implemented that way in the `Matrix` package, see the ‘Details’ below.

**Details**

Matrix multiplication with permutation matrices is equivalent to row or column permutation. Here are the four different cases for an arbitrary matrix $M$ and a permutation matrix $P$ (where we assume matching dimensions):

$$
MP = M \%\% P = M[, i(p)] \\
PM = P \%\% M = M[ p , ] \\
P'M = \text{crossprod}(P,M) (= t(P) \%\% M) = M[i(p), ] \\
MP' = \text{tcrossprod}(M,P) (= M \%\% t(P)) = M[, p ]
$$

where $p$ is the “permutation vector” corresponding to the permutation matrix $P$ (see first note), and $i(p)$ is short for `invPerm(p)`.

Also one could argue that these are really only two cases if you take into account that inversion (`solve`) and transposition (t) are the same for permutation matrices $P$.

**Objects from the Class**

Objects can be created by calls of the form `new("pMatrix", ...)` or by coercion from an integer permutation vector, see below.

**Slots**

- `Dim`: Object of class "integer". The dimensions of the matrix which must be a two-element vector of equal, non-negative integers.
- `Dimnames`: list of length two; each component containing NULL or a `character` vector length equal the corresponding `Dim` element.

**Extends**

Class "`indMatrix`", directly.
Methods

```r
%*% signature(x = "matrix", y = "pMatrix") and other signatures (use
showMethods("%*%", class="pMatrix"): ...

coerce signature(from = "integer", to = "pMatrix"): This is enables typical "pMatrix"
construction, given a permutation vector of 1:n, see the first example.

coerce signature(from = "numeric", to = "pMatrix"): a user convenience, to allow
as(perm, "pMatrix") for numeric perm with integer values.

coerce signature(from = "pMatrix", to = "matrix"): coercion to a traditional
FALSE/TRUE matrix of mode logical. (in earlier version of Matrix, it resulted in a 0/1-
integer matrix; logical makes slightly more sense, corresponding better to the “natural”
sparseMatrix counterpart, "ngTMatrix").

coerce signature(from = "pMatrix", to = "ngTMatrix"): coercion to sparse logical matrix
of class ngTMatrix.

determinant signature(x = "pMatrix", logarithm="logical"): Since permutation matri-
ces are orthogonal, the determinant must be +1 or -1. In fact, it is exactly the sign of the
permutation.

solve signature(a = "pMatrix", b = "missing"): return the inverse permutation matrix; note
that solve(P) is identical to t(P) for permutation matrices. See solve-methods for other
methods.

t signature(x = "pMatrix"): return the transpose of the permutation matrix (which is also the
inverse of the permutation matrix).

Note

For every permutation matrix P, there is a corresponding permutation vector p (of indices, 1:n), and
these are related by

```r
P <- as(p, "pMatrix")
p <- P@perm
```

see also the ‘Examples’.

“Row-indexing” a permutation matrix typically returns an "indMatrix". See "indMatrix" for all
other subsetting/indexing and subassignment (A[. , ] <- v) operations.

See Also

`invPerm` computes the inverse permutation of an integer (index) vector p.

Examples

```r
(pm1 <- as(as.integer(c(2,3,1)), "pMatrix"))
t(pm1) # is the same as
solve(pm1)
```

```r
pm1 %*% t(pm1) # check that the transpose is the inverse
stopifnot(all(diag(3) == as(pm1 %*% t(pm1), "matrix")),
is.logical(as(pm1, "matrix"))
```

```r
set.seed(11)
## random permutation matrix :
(p10 <- as(sample(10),"pMatrix"))
```
## Description

Format and print sparse matrices flexibly. These are the “workhorses” used by the `format`, `show` and `print` methods for sparse matrices. If `x` is large, `printSpMatrix2(x)` calls `printSpMatrix()` twice, namely, for the first and the last few rows, suppressing those in between, and also suppresses columns when `x` is too wide.

`printSpMatrix()` basically prints the result of `formatSpMatrix()`.

### Usage

```r
formatSpMatrix(x, digits = NULL, maxp = 1e9, 
               cld = getClassDef(class(x)), zero.print = ".", 
               col.names = note.dropping.colnames = TRUE, 
               align = c("fancy", "right"))
```

```r
printSpMatrix(x, digits = NULL, maxp = getOption("max.print"), 
               cld = getClassDef(class(x)), 
               zero.print = ".", col.names = note.dropping.colnames = TRUE, 
               col.trailer = "", 
               align = c("fancy", "right"))
```

```r
printSpMatrix2(x, digits = NULL, maxp = getOption("max.print"), 
               zero.print = ".", col.names = note.dropping.colnames = TRUE, 
               suppRows = NULL, suppCols = NULL, 
               col.trailer = if(suppCols) "......" else "", 
               align = c("fancy", "right"))
```

### Arguments

- `x`  
  - an R object inheriting from class `sparseMatrix`.

- `digits`  
  - significant digits to use for printing, see `print.default`, the default, `NULL`, corresponds to using `getOption("digits")`.

- `maxp`  
  - integer, default from `options(max.print)`, influences how many entries of large matrices are printed at all.

- `cld`  
  - the class definition of `x`; must be equivalent to `getClassDef(class(x))` and exists mainly for possible speedup.
printSpMatrix

zero.print character which should be printed for structural zeroes. The default "." may occasionally be replaced by " " (blank); using "0" would look almost like print()ing of non-sparse matrices.

col.names logical or string specifying if and how column names of x should be printed, possibly abbreviated. The default is taken from options("sparse.colnames") if that is set, otherwise FALSE unless there are less than ten columns. When TRUE the full column names are printed. When col.names is a string beginning with "abb" or "sub" and ending with an integer n (i.e., of the form "abb... <n>"), the column names are abbreviate()d or substring()ed to (target) length n, see the examples.

note.dropping.colnames logical specifying, when col.names is FALSE if the dropping of the column names should be noted, TRUE by default.

col.trailer a string to be appended to the right of each column; this is typically made use of by show(<sparseMatrix>) only, when suppressing columns.

suppRows, suppCols logicals or NULL, for printSpMatrix2() specifying if rows or columns should be suppressed in printing. If NULL, sensible defaults are determined from dim(x) and options(c("width", "max.print"). Setting both to FALSE may be a very bad idea.

align a string specifying how the zero.print codes should be aligned, i.e., padded as strings. The default, "fancy", takes some effort to align the typical zero.print = "." with the position of 0, i.e., the first decimal (one left of decimal point) of the numbers printed, whereas align = "right" just makes use of print(*, right = TRUE).

Details

formatSpMatrix: If x is large, only the first rows making up the approximately first maxp entries is used, otherwise all of x. .formatSparseSimple() is applied to (a dense version of) the matrix. Then, formatSparseM is used, unless in trivial cases or for sparse matrices without x slot.

Value

formatSpMatrix() returns a character matrix with possibly empty column names, depending on col.names etc, see above.

printSpMatrix() returns x invisibly, see invisible.

Author(s)

Martin Maechler

See Also

the virtual class sparseMatrix and the classes extending it; maybe sparseMatrix or spMatrix as simple constructors of such matrices.

The underlying utilities formatSpMatrix and .formatSparseSimple() (on the same page).
Examples

```r
f1 <- gl(5, 3, labels = LETTERS[1:5])
X <- as(f1, "sparseMatrix")
X ## show(X) ==> print(X)
t(X) ## shows column names, since only 5 columns

X2 <- as(gl(12, 3, labels = paste(LETTERS[1:12], "c", sep=".")), "sparseMatrix")
X2
## less nice, but possible:
print(X2, col.names = TRUE) # use [,1] [,2] .. => does not fit
t(X2) # suppressing column names
print(t(X2), col.names=TRUE)
print(t(X2), zero.print = ",", col.names="abbr. 1")
print(t(X2), zero.print = ",", col.names="substring 2")
```

qr-methods  \hspace{\stretch{1}}  QR Decomposition – S4 Methods and Generic

Description

The "Matrix" package provides methods for the QR decomposition of special classes of matrices. There is a generic function which uses `qr` as default, but methods defined in this package can take extra arguments. In particular there is an option for determining a fill-reducing permutation of the columns of a sparse, rectangular matrix.

Usage

```r
qr(x, ...)
qrR(qr, complete=FALSE, backPermute=TRUE)
```

Arguments

- `x` a numeric or complex matrix whose QR decomposition is to be computed. Logical matrices are coerced to numeric.
- `qr` a QR decomposition of the type computed by `qr`.
- `complete` logical indicating whether the `R` matrix is to be completed by binding zero-value rows beneath the square upper triangle.
- `backPermute` logical indicating if the rows of the `R` matrix should be back permuted such that `qrR()`’s result can be used directly to reconstruct the original matrix `X`.
- `...` further arguments passed to or from other methods

Methods

- `x = "dgCMatrix"` QR decomposition of a general sparse double-precision matrix with `nrow(x) >= ncol(x)`. Returns an object of class "sparseQR".
- `x = "sparseMatrix"` works via "dgCMatrix".
rankMatrix

Rank of a Matrix

Description

Compute 'the' matrix rank, a well-defined functional in theory, somewhat ambiguous in practice. We provide several methods, the default corresponding to Matlab's definition.

Usage

```r
rankMatrix(x, tol = NULL, 
    method = c("tolNorm2", "qr.R", "qrLINPACK", "qr", 
               "useGrad", "maybeGrad"), 
    sval = svd(x, 0, 0)$d, warn.t = TRUE)
```

Arguments

- **x**: numeric matrix, of dimension \( n \times m \), say.
- **tol**: nonnegative number specifying a (relative, "scalefree") tolerance for testing of "practically zero" with specific meaning depending on method; by default, \( \max(\dim(x)) \times .Machine\$double.eps \) is according to Matlab's default (for its only method which is our method="tolNorm2").
- **method**: a character string specifying the computational method for the rank, can be abbreviated:
  - "tolNorm2": the number of singular values \( \geq \text{tol} \times \max(\text{sval}) \);
  - "qrLINPACK": for a dense matrix, this is the rank of \( \text{qr}(x, \text{tol}, \text{LAPACK=}\text{FALSE}) \) (which is \( \text{qr}(\ldots)\$\text{rank} \));
  - This ("qr*", dense) version used to be the recommended way to compute a matrix rank for a while in the past.
  - For sparse \( x \), this is equivalent to "qr.R".

See Also

- `qr`; then, the class documentations, mainly `sparseQR`, and also `dgCMatrix`.

Examples

```r
###--------- example of pivoting -- from base' qr.Rd ---------
X <- Matrix(cbind(int = 1, 
             b1=rep(1:0, each=3), b2=rep(0:1, each=3), 
             c1=rep(c(1,0,0), 2), c2=rep(c(0,1,0), 2), c3=rep(c(0,0,1),2)), 
             sparse=TRUE)
X # is singular, columns "b2" and "c3" are "extra"
(qx <- qr(X))
# both @p and @q are non-trivial permutations
drop0(R. <- qr.R(qx), tol=1e-15) # columns are int b1 c1 c2 b2 c3
Q. <- qr.Q(qx)
q1 <- sort.list(qx@q) # the inverse 'q' permutation
(X. <- drop0(Q. *%*% R.I, q1, tol=1e-15))## just = X
stopifnot(all(X - X.) < 8*.Machine$double.eps, 
  ## qr(.) returns R already "back permuted" (as with q1):
  identical(R.I, q1, qrR(qx)))
```
"qr.R": this is the rank of triangular matrix $R$, where \texttt{qr()} uses LAPACK or a "sparseQR" method (see \texttt{qr-methods}) to compute the decomposition $ QR $. The rank of $ R $ is then defined as the number of “non-zero” diagonal entries $ d_i $ of $ R $, and “non-zero”s fulfill $ |d_i| \geq \text{tol} \cdot \text{max}(|d_i|) $.

"qr": is for back compatibility; for dense \texttt{x}, it corresponds to “\texttt{qrLINPACK}”, whereas for sparse \texttt{x}, it uses “\texttt{qr.R}”.

For all the "qr∗" methods, singular values \texttt{sval} are not used, which may be crucially important for a large sparse matrix \texttt{x}, as in that case, when \texttt{sval} is not specified, the default, computing \texttt{svd()} currently coerces \texttt{x} to a dense matrix.

"useGrad": considering the “gradient” of the (decreasing) singular values, the index of the \textit{smallest} gap.

"maybeGrad": choosing method "\texttt{useGrad}" only when that seems \textit{reasonable}; otherwise using "\texttt{tolNorm2}".

\texttt{warn.t} logical indicating if \texttt{rankMatrix()} should warn when it needs \texttt{t(x)} instead of \texttt{x}. Currently, for \texttt{method = "qr"} only, gives a warning by default because the caller often could have passed \texttt{t(x)} directly, more efficiently.

\textbf{Value}

positive integer in $1: \min(\dim(x))$, with attributes detailing the method used.

\textbf{Note}

For large sparse matrices \texttt{x}, unless you can specify \texttt{sval} yourself, currently \texttt{method = "qr"} may be the only feasible one, as the others need \texttt{sval} and call \texttt{svd()} which currently coerces \texttt{x} to a \texttt{denseMatrix} which may be very slow or impossible, depending on the matrix dimensions.

Note that in the case of sparse \texttt{x}, \texttt{method = "qr"}, all non-strictly zero diagonal entries $ d_i $ where counted, up to including \texttt{Matrix} version 1.1-0, i.e., that method implicitly used $ \text{tol} = 0 $, see also the \texttt{seed(42)} example below.

\textbf{Author(s)}

Martin Maechler; for the "*Grad" methods, building on suggestions by Ravi Varadhan.

\textbf{See Also}

\texttt{qr}, \texttt{svd}.

\textbf{Examples}

sapply(meths, function(m) rankMatrix(H12, method = m))

### tolNorm2 qr qr.R qrLINPACK useGrad maybeGrad

### 11 12 11 12 11 11
\end{verbatim}
rcond

Estimate the Reciprocal Condition Number

Description

Estimate the reciprocal of the condition number of a matrix.

This is a generic function with several methods, as seen by showMethods(rcond).

Usage

rcond(x, norm, ...)

## S4 method for signature 'sparseMatrix,character'

rcond(x, norm, useInv=FALSE, ...)

Arguments

x

an R object that inherits from the Matrix class.
**rcond**

- **norm**: character string indicating the type of norm to be used in the estimate. The default is "0" for the 1-norm ("0" is equivalent to "1"). For sparse matrices, when useInv=TRUE, norm can be any of the kinds allowed for norm; otherwise, the other possible value is "I" for the infinity norm, see also norm.

- **useInv**: logical (or "Matrix" containing solve(x)). If not false, compute the reciprocal condition number as $1/(\|x\| \cdot \|x^{-1}\|)$, where $x^{-1}$ is the inverse of $x$, solve(x). This may be an efficient alternative (only) in situations where solve(x) is fast (or known), e.g., for (very) sparse or triangular matrices.

  Note that the result may differ depending on useInv, as per default, when it is false, an approximation is computed.

- **...**: further arguments passed to or from other methods.

**Value**

An estimate of the reciprocal condition number of $x$.

**BACKGROUND**

The condition number of a regular (square) matrix is the product of the norm of the matrix and the norm of its inverse (or pseudo-inverse).

More generally, the condition number is defined (also for non-square matrices $A$) as

$$\kappa(A) = \frac{\max_{\|v\|=1} \|Av\|}{\min_{\|v\|=1} \|Av\|}.$$ 

Whenever $x$ is not a square matrix, in our method definitions, this is typically computed via rcond(qr.R(qr(X)), ... ) where $X$ is $x$ or $t(x)$.

The condition number takes on values between 1 and infinity, inclusive, and can be viewed as a factor by which errors in solving linear systems with this matrix as coefficient matrix could be magnified.

rcond() computes the reciprocal condition number $1/\kappa$ with values in $[0, 1]$ and can be viewed as a scaled measure of how close a matrix is to being rank deficient (aka “singular”).

Condition numbers are usually estimated, since exact computation is costly in terms of floating-point operations. An (over) estimate of reciprocal condition number is given, since by doing so overflow is avoided. Matrices are well-conditioned if the reciprocal condition number is near 1 and ill-conditioned if it is near zero.

**References**

**See Also**

- norm, kappa() from package base computes an approximate condition number of a “traditional” matrix, even non-square ones, with respect to the $p = 2$ (Euclidean) norm. solve.

- condest, a newer approximate estimate of the (1-norm) condition number, particularly efficient for large sparse matrices.
Examples

```r
x <- Matrix(rnorm(9), 3, 3)
rcond(x)
## typically "the same" (with more computational effort):
1 / (norm(x) * norm(solve(x)))
rcond(Hilbert(9))  # should be about 9.1e-13

## For non-square matrices:
(rcond(x1 <- cbind(1:1:10)) # 0.05278
rcond(x2 <- cbind(x1, 2:11)) # practically 0, since x2 does not have full rank

## sparse
(S1 <- Matrix(rbind(0:1,0, diag(3:-2))))
rcond(S1)
m1 <- as(S1, "denseMatrix")
all.equal(rcond(S1), rcond(m1))

## wide and sparse
rcond(Matrix(cbind(0, diag(2:-1))))

## Large sparse example -----------
(m <- Matrix(c(3:0:2), 2,2))
M <- bdiag(kronecker(Diagonal(2), m), kronecker(m,m))
36*(IM <- solve(M))  # still sparse
MM <- kronecker(Diagonal(10), kronecker(Diagonal(5),kronecker(m,M)))
dim(M3 <- kronecker(bdiag(M,M),MM))  # 12'800 ^ 2
if(interactive())  # takes about 2 seconds if you have >= 8 GB RAM
  system.time(r <- rcond(M3))
## whereas this is *fast* even though it computes solve(M3)
if(interactive())  # the values are not the same
  c(r, r)  # 0.05555 0.013888
## for all 4 norms available for sparseMatrix :
cbind(rr <- sapply(c("1","I","F","M"),
                  function(N) rcond(M3, norm=N, useInv=TRUE)))
```

---

rep2abI

Replicate Vectors into 'abIndex' Result

Description

rep2abI(x, times) conceptually computes rep.int(x, times) but with an abIndex class result.

Usage

rep2abI(x, times)

Arguments

- **x** numeric vector
- **times** integer (valued) scalar: the number of repetitions
Value

a vector of class `abIndex`

See Also

`rep.int()`, the base function; `abIseq, abIndex`.

Examples

```r
(ab <- rep2ab1(2:7, 4))
stopifnot(identical(as(ab, "numeric"),
    rep(2:7, 4)))
```

---

### replValue-class

Virtual Class "replValue" - Simple Class for subassignment Values

Description

The class "replValue" is a virtual class used for values in signatures for sub-assignment of "Matrix" matrices.

In fact, it is a simple class union (`setClassUnion`) of "numeric" and "logical" (and maybe "complex" in the future).

Objects from the Class

Since it is a virtual Class, no objects may be created from it.

See Also

`subassign-methods`, also for examples.

Examples

```r
showClass("replValue")
```

---

### rleDiff-class

Class "rleDiff" of `rle(diff(.))` Stored Vectors

Description

Class "rleDiff" is for compactly storing long vectors which mainly consist of linear stretches. For such a vector \( x \), \( \text{diff}(x) \) consists of constant stretches and is hence well compressable via \( \text{rle}() \).

Objects from the Class

Objects can be created by calls of the form `new("rleDiff", ...)`. Currently experimental, see below.
Slots

first: A single number (of class "numLike", a class union of "numeric" and "logical").

class: Object of class "rle", basically a list with components "lengths" and "values", see \rle(). As this is used to encode potentially huge index vectors, lengths may be of type double here.

Methods

There is a simple show method only.

Note

This is currently an experimental auxiliary class for the class abIndex, see there.

See Also

rle, abIndex.

Examples

showClass("rleDiff")

ab <- c(abIsseq(2, 100), abIsseq(20, -2))
ab@rleD  # is "rleDiff"

rsparsematrix  Random Sparse Matrix

Description

Generate a Random Sparse Matrix Efficiently.

Usage

rsparsematrix(nrow, ncol, density, nnz = round(density * maxE),
  symmetric = FALSE,
  rand.x = function(n) signif(rnorm(nnz), 2), ...)

Arguments

nrow, ncol number of rows and columns, i.e., the matrix dimension (dim).

density optional number in [0, 1], the density is the proportion of non-zero entries among all matrix entries. If specified it determines the default for nnz, otherwise nnz needs to be specified.

nnz number of non-zero entries, for a sparse matrix typically considerably smaller than nrow*ncol. Must be specified if density is not.

symmetric logical indicating if result should be a matrix of class symmetricMatrix. Note that in the symmetric case, nnz denotes the number of non zero entries of the upper (or lower) part of the matrix, including the diagonal.
**RsparseMatrix-class**

```r
test.x the random number generator for the x slot, a function such that test.x(n) generates a numeric vector of length n. Typical examples are test.x = rnorm, or test.x = runif; the default is nice for didactical purposes.

... optionally further arguments passed to sparseMatrix(), notably giveCsparse.
```

**Details**

The algorithm first samples “encoded” \((i,j)\)s without replacement, via one dimensional indices, if not symmetric sample.int(nrow*ncol, nnz), then gets \(x \leftarrow \text{test.x}(\text{nnz})\) and calls sparseMatrix(i=i, j=j, x=x, ...).

**Value**

A `sparseMatrix`, say \(M\) of dimension \((\text{nrow}, \text{ncol})\), i.e., with \(\text{dim}(M) = c(\text{nrow}, \text{ncol})\), if symmetric is not true, with \(\text{nzM} \leftarrow \text{nnzero}(M)\) fulfilling \(\text{nzM} \leq \text{nnz}\) and typically, \(\text{nzM} = \text{nnz}\).

**Examples**

```r
set.seed(17)# to be reproducible
M <- rsparsematrix(8, 12, nnz = 30)# small example, not very sparse
M
M1 <- rsparsematrix(1000, 20, nnz = 123, test.x = runif)
summary(M1)

## a random *symmetric* Matrix
(S9 <- rsparsematrix(9, 9, nnz = 10, symmetric=TRUE))# dCMatrix
nnzero(S9)# ~ 20: as 'nnz' only counts one "triangle"

## a [T]riplet representation sparseMatrix:
T2 <- rsparsematrix(40, 12, nnz = 99, giveCsparse=FALSE)
head(T2)
```

**Description**

Class "RsparseMatrix" of Sparse Matrices in Column-compressed Form

The "RsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed row-oriented form. Since it is a virtual class, no objects may be created from it. See showClass("RsparseMatrix") for its subclasses.

**Slots**

- \(j\): Object of class "integer" of length \(\text{nnzero}\) (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
- \(p\): Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.

**Dim, Dimnames:** inherited from the superclass, see `sparseMatrix`.
Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

Methods

Only few methods are defined currently on purpose, since we rather use the CsparseMatrix in Matrix. Recently, more methods were added but beware that these typically do not return "RsparseMatrix" results, but rather Csparse* or Tsparse* ones.

\[ \text{t signature}(x = "RsparseMatrix"):: ... \]
\[ \text{coerce signature(from = "RsparseMatrix", to = "CsparseMatrix"):: ...} \]
\[ \text{coerce signature(from = "RsparseMatrix", to = "TsparseMatrix"):: ...} \]

See Also

its superclass, sparseMatrix, and, e.g., class dgRMatrix for the links to other classes.

Examples

\[ \text{showClass("RsparseMatrix")} \]

---

Schur 

Schur Decomposition of a Matrix

Description

Computes the Schur decomposition and eigenvalues of a square matrix; see the BACKGROUND information below.

Usage

Schur(x, vectors, ...)

Arguments

\[ x \] numeric square Matrix (inheriting from class "Matrix") or traditional matrix. Missing values (NAs) are not allowed.
\[ \text{vectors} \] logical. When TRUE (the default), the Schur vectors are computed, and the result is a proper MatrixFactorization of class Schur.
\[ \text{...} \] further arguments passed to or from other methods.

Details

Based on the Lapack subroutine dgees.

Value

If vectors are TRUE, as per default: If \[ x \] is a Matrix an object of class Schur, otherwise, for a traditional matrix \[ x \], a list with components \[ T, Q \] and EValues.
If vectors are FALSE, a list with components
\[ T \] the upper quasi-triangular (square) matrix of the Schur decomposition.
\[ \text{EValues} \] the vector of numeric or complex eigen values of \( T \) or \( A \).
BACKGROUND

If $A$ is a square matrix, then $A = QTQ^T$, where $Q$ is orthogonal, and $T$ is upper block-triangular (nearly triangular with either 1 by 1 or 2 by 2 blocks on the diagonal) where the 2 by 2 blocks correspond to (non-real) complex eigenvalues. The eigenvalues of $A$ are the same as those of $T$, which are easy to compute. The Schur form is used most often for computing non-symmetric eigenvalue decompositions, and for computing functions of matrices such as matrix exponentials.

References

Examples

```r
Schur(Hilbert(9))  # Schur factorization (real eigenvalues)

(A <- Matrix(round(rnorm(5*5, sd = 100)), nrow = 5))
(Sch.A <- Schur(A))

eTA <- eigen(Sch.A@T)
str(SchA <- Schur(A, vectors=FALSE))  # no 'T' ==> simple list
stopifnot(all.equal(eTA$values, eigen(A)$values, tolerance = 1e-13),
          all.equal(eTA$values, SchA$T[order(Mod(z, decreasing=TRUE))],
                     identical(SchA$T, Sch.A@T),
                     identical(SchA$EV, Sch.A@EV))

## For the faint of heart, we provide Schur() also for traditional matrices:

a.m <- function(M) unname(as(M, "matrix"))
a <- a.m(A)
Sch.a <- Schur(a)
stopifnot(identical(Sch.a, list(Q = a.m(Sch.A @ Q),
                             T = a.m(Sch.A @ T),
                             EV = Sch.A@EV)),
           all.equal(a, with(Sch.a, Q %*% T %*% t(Q))))
```

Class "Schur" of Schur Matrix Factorizations

Description

Class "Schur" is the class of Schur matrix factorizations. These are a generalization of eigen value (or "spectral") decompositions for general (possibly asymmmetric) square matrices, see the `Schur()` function.

Objects from the Class

Objects of class "Schur" are typically created by `Schur()`.
Slots

"Schur" has slots

T: Upper Block-triangular Matrix object.
Q: Square orthogonal "Matrix".
EValues: numeric or complex vector of eigenvalues of T.
Dim: the matrix dimension: equal to c(n, n) of class "integer".

Extends

Class "MatrixFactorization", directly.

See Also

Schur() for object creation: MatrixFactorization.

Examples

showClass("Schur")
Schur(M <- Matrix(c(1:7, 10:2), 4,4))
## Trivial, of course:
str(Schur(Diagonal(5)))

## for more examples, see Schur()

Methods in Package Matrix for Function solve()

Description

Methods for function solve to solve a linear system of equations, or equivalently, solve for \( X \) in

\[
AX = B
\]

where \( A \) is a square matrix, and \( X, B \) are matrices or vectors (which are treated as 1-column matrices), and the \( R \) syntax is

\[
X \leftarrow \text{solve}(A,B)
\]

In \text{solve}(a,b) in the Matrix package, a may also be a MatrixFactorization instead of directly a matrix.

Usage

\[
\#
\text{S4 method for signature 'CHMfactor,ddenseMatrix'}
\text{solve}(a, b, \\
\text{system} = c(\text{"A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P", "Pt"}, ...)
\]

\[
\#
\text{S4 method for signature 'dgCMatrix, matrix'}
\text{solve}(a, b, \text{sparse} = \text{FALSE}, \text{tol} = \text{.Machine}$\text{double.eps}, ...)
\]

\text{solve}(a, b, ...) \# the two-argument version, almost always preferred to
\# \text{solve}(a) \quad \# the *rarely* needed one-argument version
solve-methods

Arguments

*a* a square numeric matrix, *A*, typically of one of the classes in `Matrix`. Logical matrices are coerced to corresponding numeric ones.

*b* numeric vector or matrix (dense or sparse) as RHS of the linear system *A* *x* = *b*.

*system* only if *a* is a `CHMfactor`: character string indicating the kind of linear system to be solved, see below. Note that the default, "A", does not solve the triangular system (but "L" does).

*sparse* only when *a* is a `sparseMatrix`, i.e., typically a `dgCMatrix`: logical specifying if the result should be a (formally) sparse matrix.

*tol* only used when *a* is sparse, in the `isSymmetric`(*a*, `tol=+`) test, where that applies.

... potentially further arguments to the methods.

Methods

signature(*a* = "ANY", *b* = "ANY") is simply the `base` package’s S3 generic `solve`.

signature(*a* = "CHMfactor", *b* = "...."), `system=` * The solve methods for a "CHMfactor" object take an optional third argument `system` whose value can be one of the character strings "A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P" or "Pt". This argument describes the system to be solved. The default, "A", is to solve *A* *x* = *b* for *x* where *A* is sparse, positive-definite matrix that was factored to produce *a*. Analogously, `system = "L"` returns the solution *x* of *L* *x* = *b*; similarly, for all system codes `but "P"` and "Pt" where, e.g., *x* <- solve(*a*, *b*, `system="P"`) is equivalent to *x* <- *P* %*% *b*.

If *b* is a `sparseMatrix`, `system` is used as above the corresponding sparse CHOLMOD algorithm is called.

signature(*a* = "ddenseMatrix", *b* = "....") (for all *b*) work via `as(*a*, "dgeMatrix")`, using its methods, see below.

signature(*a* = "denseLU", *b* = "missing") basically computes uses triangular forward- and back-solve.

signature(*a* = "dgCMatrix", *b* = "matrix"), and

signature(*a* = "dgCMatrix", *b* = "ddenseMatrix") with extra argument list (`sparse = FALSE`, `tol` = `.Machine$double.eps`) : Uses the sparse `lu`(*a*) decomposition (which is cached in `a`’s factor slot). By default, `sparse=FALSE`, returns a `denseMatrix`, since *U*⁻¹ *L*⁻¹ *B* may not be sparse at all, even when *L* and *U* are.

If `sparse=TRUE`, returns a `sparseMatrix` (which may not be very sparse at all, even if a was sparse).

signature(*a* = "dgCMatrix", *b* = "dsparseMatrix"), and

signature(*a* = "dgCMatrix", *b* = "missing") with extra argument list (`sparse=FALSE`, `tol` = `.Machine$double.eps`) : Checks if *a* is symmetric, and in that case, coerces it to "symmetricMatrix", and then computes a sparse solution via sparse Cholesky factorization, independently of the `sparse` argument. If a is not symmetric, the sparse `lu` decomposition is used and the result will be sparse or dense, depending on the `sparse` argument, exactly as for the above (`b` = "ddenseMatrix") case.

signature(*a* = "dgeMatrix", *b* = "....") solve the system via internal LU, calling LAPACK routines `dgetri` or `dgetrs`.

signature(*a* = "diagonalMatrix", *b* = "matrix") and other bs: Of course this is trivially implemented, as *D*⁻¹ is diagonal with entries 1/*D*[i, i].
signature(a = "dpoMatrix", b = "....Matrix") .and
signature(a = "dppMatrix", b = "....Matrix") The Cholesky decomposition of a is calculated (if needed) while solving the system.

signature(a = "dsCMatrix", b = "....") All these methods first try Cholmod’s Cholesky factorization; if that works, i.e., typically if a is positive semi-definite, it is made use of. Otherwise, the sparse LU decomposition is used as for the “general” matrices of class "dgCMatrix".

signature(a = "dspMatrix", b = "....") .and
signature(a = "dsyMatrix", b = "....") all end up calling LAPACK routines dsprtr, dsptrs, dsytrs and dsytri.

signature(a = "dtCMatrix", b = "CsparseMatrix") ,
signature(a = "dtTMatrix", b = "dgeMatrix") , etc sparse triangular solve, in traditional S/R also known as backsolve, or forwardsolve. solve(a,b) is a sparseMatrix if b is, and hence a denseMatrix otherwise.

signature(a = "dtrMatrix", b = "ddenseMatrix") .and
signature(a = "dtpMatrix", b = "matrix") , and similar b, including "missing", and "diagonalMatrix":
   all use LAPACK based versions of efficient triangular backsolve, or forwardsolve.

signature(a = "Matrix", b = "diagonalMatrix") works via as(b, "CsparseMatrix").

signature(a = "sparseQR", b = "ANY") simply uses qr.coef(a, b).

signature(a = "pMatrix", b = "....") these methods typically use crossprod(a,b), as the inverse of a permutation matrix is the same as its transpose.

signature(a = "TsparseMatrix", b = "ANY") all work via as(a, "CsparseMatrix").

Examples

```r
## A close to symmetric example with "quite sparse" inverse:
n1 <- 7; n2 <- 3
dd <- data.frame(a = gl(n1,n2), b = gl(n2,1,n1*n2))# balanced 2-way
X <- sparse.model.matrix(~ -1+ a + b, dd)# no intercept --> even sparser
XXt <- tcrossprod(X)
diag(XXt) <- rep(c(0,0,1,0), length.out = nrow(XXt))

n <- nrow(ZZ <- kronecker(XXt, Diagonal(x=c(4,1))))
image(a <- 2*Diagonal(n) + ZZ %x% Diagonal(x=c(10, rep(1, n-1))))
isSymmetric(a) # FALSE
image(drop0(skewpart(a)))
image(ia0 <- solve(a)) # checker board, dense [but really, a is singular!]
try(solve(a, sparse=TRUE))##-> error [ TODO: assertError ]
ia. <- solve(a, sparse=TRUE, tol = 1e-19)##-> *no* error
if(R.version$arch == "x86_64")
   ## Fails on 32-bit [Fedora 19, R 3.0.2] from Matrix 1.1-0 on [FIXME ??] only
stopifnot(all.equal(as.matrix(ia.), as.matrix(ia0)))
a <- a + Diagonal(n)
ias <- solve(a)
ias <- solve(a, sparse=TRUE)
stopifnot(all.equal(as(ias,"denseMatrix"), iad, tolerance=1e-14))
I. <- iad %x% a ; image(I.)
```
sparse.model.matrix

Description

Construct a sparse model or “design” matrix, form a formula and data frame (sparse.model.matrix) or a single factor (fac2sparse).

The fac2sparse() functions are utilities, also used internally in the principal user level function sparse.model.matrix().

Usage

sparse.model.matrix(object, data = environment(object),
  contrasts.arg = NULL, xlev = NULL, transpose = FALSE,
  drop.unused.levels = FALSE, row.names = TRUE,
  verbose = FALSE, ...)

fac2sparse(from, to = c("d", "i", "1", "n", "z"),
  drop.unused.levels = TRUE, giveCsparse = TRUE)
fac2Sparse(from, to = c("d", "i", "1", "n", "z"),
  drop.unused.levels = TRUE, giveCsparse = TRUE,
  factorPatt12, contrasts.arg = NULL)

Arguments

object an object of an appropriate class. For the default method, a model formula or terms object.
data a data frame created with model.frame. If another sort of object, model.frame is called first.
contrasts.arg for sparse.model.matrix(): A list, whose entries are contrasts suitable for input to the contrasts replacement function and whose names are the names of columns of data containing factors.
  for fac2sparse(): character string or NULL or (coercable to) "sparseMatrix", specifying the contrasts to be applied to the factor levels.
xlev to be used as argument of model.frame if data has no "terms" attribute.
transpose logical indicating if the transpose should be returned; if the transposed is used anyway, setting transpose = TRUE is more efficient.
drop.unused.levels should factors have unused levels dropped? The default for sparse.model.matrix has been changed to FALSE, 2010-07, for compatibility with R’s standard (dense) model.matrix().
row.names logical indicating if row names should be used.
verbose logical or integer indicating if (and how much) progress output should be printed.
... further arguments passed to or from other methods.
from (for fac2sparse()): a factor.
to a character indicating the “kind” of sparse matrix to be returned. The default, "d" is for double.
giveCSparse (for fac2sparse()): logical indicating if the result must be a CsparseMatrix.
factorPatt12 logical vector, say fp, of length two; when fp[1] is true, return “contrasted” t(X); when fp[2] is true, the original (“dummy”) t(X), i.e. the result of fac2sparse().

Value

a sparse matrix, extending CsparseMatrix (for fac2sparse() if giveCSparse is true as per default; a TsparseMatrix, otherwise).

For fac2Sparse(), a list of length two, both components with the corresponding transposed model matrix, where the corresponding factorPatt12 is true.

Note that model.Matrix(*, sparse=TRUE) from package MatrixModels may be often be preferable to sparse.model.matrix() nowadays, as model.Matrix() returns modelMatrix objects with additional slots assign and contrasts which relate back to the variables used.

fac2sparse(), the basic workhorse of sparse.model.matrix(), returns the transpose (t) of the model matrix.

Author(s)

Doug Bates and Martin Maechler, with initial suggestions from Tim Hesterberg.

See Also

model.matrix in standard R’s package stats.
model.Matrix which calls sparse.model.matrix or model.matrix depending on its sparse argument may be preferred to sparse.model.matrix.

as(f, "sparseMatrix") (see coerce(from = "factor", ..) in the class doc sparseMatrix) produces the transposed sparse model matrix for a single factor f (and no contrasts).

Examples

dd <- data.frame(a = gl(3,4), b = gl(4,1,12))# balanced 2-way
options("contrasts") # the default: "contr.treatment"
sparse.model.matrix(~ a + b, dd)
sparse.model.matrix(~ -1+ a + b, dd)# no intercept --> even sparser
sparse.model.matrix(~ a + b, dd, contrasts = list(a="contr.sum"))
sparse.model.matrix(~ a + b, dd, contrasts = list(b="contr.SAS"))

## Sparse method is equivalent to the traditional one :
stopifnot(all(sparse.model.matrix(~ a + b, dd) ==
            Matrix(model.matrix(~ a + b, dd), sparse=TRUE)),
        all(sparse.model.matrix(~ 0+ a + b, dd) ==
            Matrix(model.matrix(~ 0+ a + b, dd), sparse=TRUE)))
Objects of this class contain the components of the LU decomposition of a sparse square matrix.

Objects from the Class

Objects can be created by calls of the form `new("sparseLU", ...)` but are more commonly created by function `lu()` applied to a sparse matrix, such as a matrix of class `dgCMatrix`.

Slots

L: Object of class "dtCMatrix", the lower triangular factor from the left.
U: Object of class "dtCMatrix", the upper triangular factor from the right.
p: Object of class "integer", permutation applied from the left.
q: Object of class "integer", permutation applied from the right.
Dim: the dimension of the original matrix; inherited from class `MatrixFactorization`.

Extends

Class "LU", directly. Class "MatrixFactorization", by class "LU".

Methods

`expand` signature(x = "sparseLU") Returns a list with components P, L, U, and Q, where P and Q represent fill-reducing permutations, and L and U the lower and upper triangular matrices of the decomposition. The original matrix corresponds to the product $PLUQ$. 

```r
(ff <- gl(3,4, , c("X","Y", "Z")))
fac2sparse(ff) # 3 x 12 sparse Matrix of class "dgCMatrix"
##
## X 1 1 1 1 .... ....
## Y .... 1 1 1 1 ....
## Z .... .... .... 1 1 1
##
## can also be computed via sparse.model.matrix():
f30 <- gl(3,0 )
f12 <- gl(3,0, 12)
stopifnot(
  all.equal(t( fac2 sparse(ff) ),
    sparse.model.matrix(~ 0+ff),
    tolerance = 0, check.attributes=FALSE),
  is(M <- fac2sparse(f30, drop= TRUE),"CsparseMatrix"), dim(M) == c(0, 0),
  is(M <- fac2sparse(f30, drop=FALSE),"CsparseMatrix"), dim(M) == c(3, 0),
  is(M <- fac2sparse(f12, drop= TRUE),"CsparseMatrix"), dim(M) == c(0,12),
  is(M <- fac2sparse(f12, drop=FALSE),"CsparseMatrix"), dim(M) == c(3,12)
)
```

sparseMatrix

General Sparse Matrix Construction from Nonzero Entries

Description

User friendly construction of a compressed, column-oriented, sparse matrix, inheriting from class CsparseMatrix (or TsparseMatrix if giveCsparse is false), from locations (and values) of its non-zero entries.

This is the recommended user interface rather than direct new("***Matrix", ....) calls.

Usage

sparseMatrix(i = ep, j = ep, p, x, dims, dimnames,
  symmetric = FALSE, index1 = TRUE,
  giveCsparse = TRUE, check = TRUE, use.last.ij = FALSE)

Arguments

i, j integer vectors of the same length specifying the locations (row and column indices) of the non-zero (or non-TRUE) entries of the matrix. Note that for repeated pairs \((i_k, j_k)\), when \(x\) is not missing, the corresponding \(x_k\) are added, in consistency with the definition of the "TsparseMatrix" class, unless use.last.ij is true, in which case only the last of the corresponding \((i_k, j_k, x_k)\) triplet is used.

p numeric (integer valued) vector of pointers, one for each column (or row), to the initial (zero-based) index of elements in the column (or row). Exactly one of \(i\) or \(p\) must be missing.

x optional values of the matrix entries. If specified, must be of the same length as \(i / j\), or of length one where it will be recycled to full length. If missing, the resulting matrix will be a 0/1 pattern matrix, i.e., extending class nsparseMatrix.

dims optional, non-negative, integer, dimensions vector of length 2. Defaults to (max(i), max(j)).

dimnames optional list of dimnames; if not specified, none, i.e., NULL ones, are used.

symmetric logical indicating if the resulting matrix should be symmetric. In that case, only the lower or upper triangle needs to be specified via \((i / j / p)\).
index1 logical scalar. If TRUE, the default, the index vectors i and/or j are 1-based, as is the convention in R. That is, counting of rows and columns starts at 1. If FALSE the index vectors are 0-based so counting of rows and columns starts at 0; this corresponds to the internal representation.
giveCsparse logical indicating if the result should be a CsparseMatrix or a TsparseMatrix. The default, TRUE is very often more efficient subsequently, but not always.
check logical indicating if a validity check is performed; do not set to FALSE unless you know what you’re doing!
use.last.ij logical indicating if in the case of repeated, i.e., duplicated pairs (i_k, j_k) only the last one should be used. The default, FALSE, corresponds to the "TsparseMatrix" definition.

Details

Exactly one of the arguments i, j and p must be missing.

In typical usage, p is missing, i and j are vectors of positive integers and x is a numeric vector. These three vectors, which must have the same length, form the triplet representation of the sparse matrix.

If i or j is missing then p must be a non-decreasing integer vector whose first element is zero. It provides the compressed, or “pointer” representation of the row or column indices, whichever is missing. The expanded form of p, rep(seq_along(dp), dp) where dp <- diff(p), is used as the (1-based) row or column indices.

The values of i, j, p and index1 are used to create 1-based index vectors i and j from which a TsparseMatrix is constructed, with numerical values given by x, if non-missing. Note that in that case, when some pairs (i_k, j_k) are repeated (aka “duplicated”), the corresponding x_k are added, in consistency with the definition of the "TsparseMatrix" class, unless use.last.ij is set to true.

By default, when giveCsparse is true, the CsparseMatrix derived from this triplet form is returned.

The reason for returning a CsparseMatrix object instead of the triplet format by default is that the compressed column form is easier to work with when performing matrix operations. In particular, if there are no zeros in x then a CsparseMatrix is a unique representation of the sparse matrix.

Value

A sparse matrix, by default (see giveCsparse) in compressed, column-oriented form, as an R object inheriting from both CsparseMatrix and generalMatrix.

Note

You do need to use index1 = FALSE (or add + 1 to i and j) if you want use the 0-based i (and j) slots from existing sparse matrices.

See Also

Matrix(*, sparse=TRUE) for the constructor of such matrices from a dense matrix. That is easier in small sample, but much less efficient (or impossible) for large matrices, where something like sparseMatrix() is needed. Further bdiag and Diagonal for (block-)diagonal and bandSparse for banded sparse matrix constructors.

The standard R xtabs(*, sparse=TRUE), for sparse tables and sparse.model.matrix() for building sparse model matrices.

Consider CsparseMatrix and similar class definition help files.
Examples

```r
## simple example
i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
(A <- sparseMatrix(i, j, x = x))
summary(A)
str(A) # note that internally 0-based row indices are used

## dims can be larger than the maximum row or column indices
(AA <- sparseMatrix(c(1,3:8), c(2,9,6:10), x = 7 * (1:7), dims = c(10,20)))
summary(AA)

## i, j and x can be in an arbitrary order, as long as they are consistent
set.seed(1); (perm <- sample(1:7))
(A1 <- sparseMatrix(i[perm], j[perm], x = x[perm]))
stopifnot(identical(A, A1))

## The slots are 0-index based, so
try( sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x)) )
## fails and you should say so: 1-indexing is FALSE:
sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x), index1 = FALSE)

## the (i,j) pairs can be repeated, in which case the x's are summed
(args <- data.frame(i = c(1, 1), j = c(j, 2), x = c(x, 2)))
(Aa <- do.call(sparseMatrix, args))
## explicitly ask for elimination of such duplicates, so
## that the last one is used:
(A. <- do.call(sparseMatrix, c(args, list(use.last.ij = TRUE))))
stopifnot(Aa[1,2] == 9, # 2*7 == 9
  A.[1,2] == 2) # 2 was *after* 7

## for a pattern matrix, of course there is no "summing":
(nA <- do.call(sparseMatrix, args[c("i","j")]))

dn <- list(LETTERS[1:3], letters[1:5])
## pointer vectors can be used, and the (i,x) slots are sorted if necessary:
m <- sparseMatrix(i = c(3,1, 3:2, 2:1), p= c(0:2, 4,4,6), x = 1:6, dimnames = dn)

  validObject(XX)
  ## Alternatively, and even more user friendly :
  X. <- as(X, "Matrix")  # or also
  X2 <- as(X, "sparseMatrix")
  stopifnot(identical(XX, X.), identical(X., X2))
}
**cbind2** (x = *, y = *): several methods for binding matrices together, column-wise, see the basic `cbind` and `rbind` functions.

Note that the result will typically be sparse, even when one argument is dense and larger than the sparse one.

**rbind2** (x = *, y = *): binding matrices together row-wise, see `cbind2` above.

**determinant** (x = "sparseMatrix", logarithm=TRUE): `determinant()` methods for sparse matrices typically work via Cholesky or lu decompositions.

**diag** (x = "sparseMatrix"): extracts the diagonal of a sparse matrix.

**dim<-** signature(x = "sparseMatrix", value = "ANY"): allows to reshape a sparse matrix to a sparse matrix with the same entries but different dimensions. value must be of length two and fulfill \( \text{prod(value)} = \text{prod(dim(x))} \).

**coerce** signature(from = "factor", to = "sparseMatrix"): Coercion of a factor to "sparseMatrix" produces the matrix of indicator rows stored as an object of class "dgCMatrix". To obtain columns representing the interaction of the factor and a numeric covariate, replace the "x" slot of the result by the numeric covariate then take the transpose. Missing values (NA) from the factor are translated to columns of all 0s.

See also `colSums`, `norm`, ... for methods with separate help pages.

**Note**

In method selection for multiplication operations (i.e. `**` and the two-argument form of `crossprod`) the sparseMatrix class takes precedence in the sense that if one operand is a sparse matrix and the other is any type of dense matrix then the dense matrix is coerced to a dgeMatrix and the appropriate sparse matrix method is used.

**See Also**

`sparseMatrix`, and its references, such as `xtabs(*, sparse=TRUE)`, or `sparse.model.matrix()`, for constructing sparse matrices.

`T2graph` for conversion of "graph" objects (package `graph`) to and from sparse matrices.

**Examples**

```r
showClass("sparseMatrix") ## and look at the help() of its subclasses
M <- Matrix(0, 10000, 100)
M[1,1] <- M[2,3] <- 3.14
M ## show(.) method suppresses printing of the majority of rows
data(CAex); dim(CAex) # 72 x 72 matrix
determinant(CAex) # works via sparse lu(.)

## factor -> t( <sparse design matrix> ) :
(fact <- gl(5, 3, 30, labels = LETTERS[1:5]))
(Xt <- as(fact, "sparseMatrix")) # indicator rows

## missing values --> all-0 columns:
f.mis <- fact
i.mis <- c(3:5, 17)
is.na(f.mis) <- i.mis
Xt !=(X. <- as(f.mis, "sparseMatrix")) # differ only in columns 3:5,17
stopifnot(all(X.[,i.mis] == 0), all(Xt[-,i.mis] == X.[,-i.mis]))
```
sparseQR-class

Sparse QR decomposition of a sparse matrix

Description

Objects class "sparseQR" represent a QR decomposition of a sparse \( n \times p \) rectangular matrix \( X \), typically resulting from \( qr() \)

Details

The decomposition is of the form \( A[p+1,] \equiv Q \times R \), if the \( q \) slot is of length 0 or \( A[p+1,q+1] \equiv Q \times R \) where \( A \) is a sparse \( m \times n \) matrix (\( m \geq n \)), \( R \) is an \( m \times n \) matrix that is zero below the main diagonal. The \( p \) slot is a 0-based permutation of \( 1:m \) applied to the rows of the original matrix. If the \( q \) slot has length \( n \) it is a 0-based permutation of \( 1:n \) applied to the columns of the original matrix to reduce the amount of "fill-in" in the matrix \( R \).
