

# Package ‘RProtoBuf’

March 28, 2020

**Version** 0.4.17

**Date** 2020-03-26

**Author** Romain Francois, Dirk Eddelbuettel, Murray Stokely and Jeroen Ooms

**Maintainer** Dirk Eddelbuettel <edd@debian.org>

**Title** R Interface to the 'Protocol Buffers' 'API' (Version 2 or 3)

**Description** Protocol Buffers are a way of encoding structured data in an efficient yet extensible format. Google uses Protocol Buffers for almost all of its internal 'RPC' protocols and file formats. Additional documentation is available in two included vignettes one of which corresponds to our 'JSS' paper (2016, <doi:10.18637/jss.v071.i02>). Either version 2 or 3 of the 'Protocol Buffers' 'API' is supported.

**Depends** R (>= 3.0.0), methods

**Imports** utils, stats, tools, Rcpp, RCurl

**LinkingTo** Rcpp

**Suggests** tinytest

**SystemRequirements** ProtoBuf libraries and compiler version 2.2.0 or later; version 3.0.0 or later is supported as well. On Debian/Ubuntu these can be installed as libprotoc-dev, libprotobuf-dev and protobuf-compiler, while on Fedora/CentOS protobuf-devel and protobuf-compiler are needed.

**BugReports** <https://github.com/eddelbuettel/rprotobuf/issues>

**URL** <https://github.com/eddelbuettel/rprotobuf>

**License** GPL (>= 2)

**NeedsCompilation** yes

**Repository** CRAN

**Date/Publication** 2020-03-28 05:50:25 UTC

RProtoBuf-package      *R Interface to the Protocol Buffers API*

---

## Description

Protocol Buffers are a way of encoding structured data in an efficient yet extensible format. Google uses Protocol Buffers for almost all of its internal RPC protocols and file formats.

This package provides R API to create, manipulate, parse and serialize protocol buffer messages from R

## Author(s)

Romain Francois, Dirk Eddelbuettel, Murray Stokely and Jeroen Ooms.

## References

<https://github.com/eddelbuettel/rprotobuf>

## See Also

[Message](#) for some examples

**Examples**

```
## Not run:
# an example proto file
system.file( "proto", "addressbook.proto", package = "RProtoBuf" )

# create a message of type AddressBook, defined in the example proto file
demo( "addressbook", package = "RProtoBuf" )

# using R binary connections and files to read and write messages
demo( "io", package = "RProtoBuf" )

# more documentation in the vignette
vignette( "RProtoBuf", package = "RProtoBuf" )

## End(Not run)
```

---

 add-methods

*add elements of a repeated field of a message*

---

**Description**

Add elements to a repeated field of a message.

**Methods**

signature(object = "Message") add elements to a repeated field of a message

**Examples**

```
unittest.proto.file <- system.file("tinytest", "data", "unittest.proto",
  package = "RProtoBuf" )
readProtoFiles(file = unittest.proto.file)

test <- new(protobuf_unittest.TestAllTypes)
test$add("repeated_int32", 1)
test$add("repeated_int32", 2:10)
test$repeated_int32
```

---

 ArrayInputStream-class

*Class "ArrayInputStream"*

---

**Description**

A [ZeroCopyInputStream](#) backed by an in-memory array of bytes

## Objects from the Class

Objects can be created by the [ArrayInputStream](#) function

## Slots

pointer: External pointer to the `google::protobuf::io::ArrayInputStream` C++ object

## Extends

Class "[ZeroCopyInputStream](#)", directly.

## Methods

See [ZeroCopyInputStream](#)

## Author(s)

Romain Francois <[francoisromain@free.fr](mailto:francoisromain@free.fr)>

## References

The ArrayInputStream class from the protobuf C++ library. [http://code.google.com/apis/protocolbuffers/docs/reference/cpp/google.protobuf.io.zero\\_copy\\_stream\\_impl\\_lite.html#ArrayInputStream](http://code.google.com/apis/protocolbuffers/docs/reference/cpp/google.protobuf.io.zero_copy_stream_impl_lite.html#ArrayInputStream)

## See Also

[ZeroCopyInputStream](#) for methods

## Examples

```
stream <- ArrayInputStream(as.raw(0:10))
stream$ReadRaw(5)

stringstream <- ArrayInputStream(as.raw(c(0x74, 0x65, 0x73, 0x74, 0x69, 0x6e, 0x67)))
stringstream$ReadString(7)

intstream <- ArrayInputStream(as.raw(c(0x9e, 0xa7, 0x05)))
intstream$ReadVarint32()
```

ArrayInputStream-methods

*Creates an ArrayInputStream*

---

### Description

Constructor for [ArrayInputStream](#) objects

### Methods

signature(payload = "raw", block\_size = "missing" ) Creates a [ArrayInputStream](#) using the raw vector as the payload of the stream

signature(payload = "raw", block\_size = "integer" ) Creates a [ArrayInputStream](#) ... same with block size.

signature(payload = "raw", block\_size = "numeric" ) Creates a [ArrayInputStream](#) ... same with block size.

---

ArrayOutputStream-class

*Class "ArrayOutputStream"*

---

### Description

A [ZeroCopyOutputStream](#) backed by an in-memory array of bytes

### Objects from the Class

Objects can be created by the [ArrayOutputStream](#) function

### Slots

pointer: External pointer to the google::protobuf::io::ArrayOutputStream C++ object

### Extends

Class "[ZeroCopyOutputStream](#)", directly.

### Methods

See [ZeroCopyOutputStream](#)

### Author(s)

Romain Francois <francoisromain@free.fr>

**References**

The ArrayOutputStream class from the protobuf C++ library. [http://code.google.com/apis/protocolbuffers/docs/reference/cpp/google.protobuf.io.zero\\_copy\\_stream\\_impl\\_lite.html#ArrayOutputStream](http://code.google.com/apis/protocolbuffers/docs/reference/cpp/google.protobuf.io.zero_copy_stream_impl_lite.html#ArrayOutputStream)

**See Also**

[ZeroCopyOutputStream](#) for methods

---

ArrayOutputStream-methods

*Creates an ArrayOutputStream*

---

**Description**

Constructor for [ArrayOutputStream](#) objects

**Methods**

signature(size = "integer", block\_size = "missing" ) Creates a [ArrayOutputStream](#) using of the given size

signature(size = "integer", block\_size = "integer" ) Creates a [ArrayOutputStream](#) ... same with block size.

signature(size = "integer", block\_size = "numeric" ) Creates a [ArrayOutputStream](#) ... same with block size.

signature(size = "numeric", block\_size = "missing" ) Creates a [ArrayOutputStream](#) using of the given size

signature(size = "numeric", block\_size = "integer" ) Creates a [ArrayOutputStream](#) ... same with block size.

signature(size = "numeric", block\_size = "numeric" ) Creates a [ArrayOutputStream](#) ... same with block size.

---

as.list.Message

*Grab the protocol buffer message as an R list*

---

**Description**

Utility to grab the protocol buffer message as an R list, with one item per field.

## Usage

```
## S3 method for class 'Message'  
as.list(x, ...)  
## S3 method for class 'Descriptor'  
as.list(x, ...)  
## S3 method for class 'EnumDescriptor'  
as.list(x, ...)  
## S3 method for class 'FileDescriptor'  
as.list(x, ...)  
## S3 method for class 'ServiceDescriptor'  
as.list(x, ...)
```

## Arguments

x	A protocol buffer message, instance of <a href="#">Message</a> , or a protocol message descriptor, instance of <a href="#">Descriptor</a>
...	ignored

## Value

For messages, a list of the content of the fields is returned.

For message type descriptors, a list containing nested type descriptors ([Descriptor](#) objects), enum type descriptors ([EnumDescriptor](#) objects), then field descriptors ([FieldDescriptor](#) objects) in that order.

For enum descriptors, a named list of the enumerated values.

For file descriptors, a named list of descriptors defined in the specified file descriptor.

For service descriptors, ...

## Author(s)

Romain Francois <francoisromain@free.fr>

## Examples

```
Person <- P( "tutorial.Person" )  
romain <- new( Person, email = "francoisromain@free.fr", id = 1 )  
as.list( romain )  
as.list( Person )  
as.list( Person$PhoneType)
```

---

asMessage	<i>coerce an object to a protobuf message</i>
-----------	---

---

### Description

coerce an object to the [Message](#) class. This is a short-hand to the [as](#) method with the Class argument set to "Message"

### Usage

```
asMessage(x, ...)
```

### Arguments

x	object to coerce to a protobuf message
...	Passed to <a href="#">as</a>

### Value

a [Message](#) object

### Author(s)

Romain Francois <francoisromain@free.fr>

### Examples

```
# coerce a message type descriptor to a message
asMessage( tutorial.Person )

# coerce a enum descriptor
asMessage( tutorial.Person.PhoneType )

# coerce a field descriptor
asMessage( tutorial.Person$email )

# coerce a file descriptor
asMessage( fileDescriptor( tutorial.Person ) )
```

---

BackUp-methods      *Backs up a number of bytes from a stream*

---

**Description**

Backs up a number of bytes from a stream

**See Also**

[ZeroCopyInputStream](#) implements BackUp.

---

ByteCount-methods      *The number of bytes read/written since the object was created*

---

**Description**

The number of bytes read/written since the object was created

**See Also**

[ZeroCopyInputStream](#) implements ByteCount.

---

bytesize-methods      *The number of bytes taken by a message*

---

**Description**

The number of bytes taken by a [Message](#)

**Methods**

signature(object = "Message") The number of bytes the message would take when serialized

**Examples**

```
message <- new( tutorial.Person, name = "dddd", email = "eeeeeee", id = 1 )
bytesize( message )
```

---

clear-methods	<i>Clear a field or all fields of the message and set them to their default values</i>
---------------	--

---

**Description**

Clear one field or all fields of the message and set them to their default values

**Methods**

signature(object = "Message", field = "missing") Clear all fields of the message and set them to their default values

signature(object = "Message", field = "character") Clear the field identified by its name

signature(object = "Message", field = "integer") Clear the field identified by its tag number

signature(object = "Message", field = "numeric") Clear the field identified by its tag number

signature(object = "Message", field = "raw") Clear the field identified by its tag number

**Examples**

```
message <- new( tutorial.Person, name = "dddd", email = "eeeeeee", id = 1 )
writeLines( as.character( message ) )
clear( message )
# clear works also as a pseudo method :
message$clear()

writeLines( as.character( message ) )

# clear single fields
message <- new( tutorial.Person, name = "dddd", email = "eeeeeee", id = 1 )
message$clear( "name" )
writeLines( as.character( message ) )
```

---

clone-methods	<i>Clone protocol buffer messages</i>
---------------	---------------------------------------

---

**Description**

Generic "clone" function and associated method for [Message](#) objects

**Methods**

signature(object = "Message") clone the message

**Examples**

```
## Not run:
# example proto file supplied with this package
proto.file <- system.file( "proto", "addressbook.proto", package = "RProtoBuf" )

# reading a proto file and creating the descriptor
Person <- P( "tutorial.Person", file = proto.file )

## End(Not run)

# creating a prototype message from the descriptor
sheep <- new( Person, email = "francoisromain@free.fr", id = 2 )

# cloning the sheep
newsheep <- clone( sheep )

# clone and update at once
newsheep <- clone( sheep, id = 3 )

# this can also be used as a pseudo method
sheep$clone()
sheep$clone( id = 3 )
```

---

 completion

*Completion support for protocol buffer messages and descriptors*

---

**Description**

These functions support completion of protocol buffer messages and descriptors.

**Usage**

```
## S3 method for class 'Message'
.DollarNames(x, pattern = "")
## S3 method for class 'Descriptor'
.DollarNames(x, pattern = "")
## S3 method for class 'EnumDescriptor'
.DollarNames(x, pattern = "")
## S3 method for class 'FieldDescriptor'
.DollarNames(x, pattern = "")
## S3 method for class 'FileDescriptor'
.DollarNames(x, pattern = "")
## S3 method for class 'ServiceDescriptor'
.DollarNames(x, pattern = "")
## S3 method for class 'MethodDescriptor'
.DollarNames(x, pattern = "")
## S3 method for class 'ZeroCopyInputStream'
```

```
.DollarNames(x, pattern = "")
## S3 method for class 'ZeroCopyOutputStream'
.DollarNames(x, pattern = "")
```

### Arguments

x                    message ([Message](#)) or descriptor ([Descriptor](#))  
 pattern            filter

### Value

Character vector containing potential completions.

For [Message](#) objects, completions are the fields of the message and a set of pseudo methods ("has")

For [EnumDescriptor](#) objects, completions are the names of the possible constants

For [Descriptor](#) objects, completions are the names of the fields, enum types and nested message types defined in the associated message type.

For [FileDescriptor](#) objects, completions are the names of the top-level descriptors (message, enum or service) contained in the associated file, or pseudo methods.

### Author(s)

Romain Francois <francoisromain@free.fr>

### Examples

```
# creating a prototype message from the descriptor
p <- new( tutorial.Person )

.DollarNames( p )
.DollarNames( tutorial.Person )
# but this is usually used with the <TAB> expansion on the command line
# <TAB> means "press the TAB key"
# p$<TAB>
# Person$<TAB>
```

---

```
ConnectionInputStream-class
      Class "ConnectionInputStream"
```

---

### Description

A [ZeroCopyInputStream](#) reading from a binary R connection

### Objects from the Class

Objects can be created by the [ConnectionInputStream](#) function

**Slots**

pointer: External pointer to the rprotobuf::ConnectionInputStream C++ object

**Extends**

Class "[ZeroCopyInputStream](#)", directly.

**Methods**

See [ZeroCopyInputStream](#)

**Author(s)**

Romain Francois <francoisromain@free.fr>

**References**

The internal C++ class ConnectionInputStream

**See Also**

[ZeroCopyInputStream](#) for methods

---

ConnectionInputStream-methods

*Creates an ConnectionInputStream*

---

**Description**

Constructor for [ConnectionInputStream](#) objects

**Methods**

signature(object="connection") Creates a [ConnectionInputStream](#) reading from the given R binary connection.

---

ConnectionOutputStream-class  
*Class "ConnectionOutputStream"*

---

**Description**

A [ZeroCopyOutputStream](#) writing to a binary R connection

**Objects from the Class**

Objects can be created by the [ConnectionOutputStream](#) function

**Slots**

pointer: External pointer to the rprotobuf::ConnectionOutputStream C++ object

**Extends**

Class "[ZeroCopyOutputStream](#)", directly.

**Methods**

See [ZeroCopyOutputStream](#)

**Author(s)**

Romain Francois <francoisromain@free.fr>

**References**

The internal C++ class ConnectionOutputStream

**See Also**

[ZeroCopyOutputStream](#) for methods

---

ConnectionOutputStream-methods  
*Creates an ConnectionOutputStream*

---

**Description**

Constructor for [ConnectionOutputStream](#) objects

**Methods**

signature(object="connection") Creates a [ConnectionOutputStream](#) writing to the given R binary connection.

---

containing\_type-methods

*Gets the message type descriptor that contains a descriptor*

---

### Description

Gets a [Descriptor](#) describing the message type that contains the descriptor.

### See Also

The method is implemented for these classes : [Descriptor](#), [EnumDescriptor](#), [FieldDescriptor](#)

### Examples

```
# Containing type of a field is the message descriptor
tutorial.Person$id$containing_type()

# No containing type for the top-level message descriptor.
tutorial.Person$containing_type()
```

---

Descriptor-class

*Class "Descriptor"*

---

### Description

full descriptive information about a protocol buffer message type. This is a thin wrapper around the C++ class `Descriptor`

### Objects from the Class

Objects are usually created by calls to the `P` function.

### Slots

**pointer:** external pointer holding a `Descriptor` object

**type:** full name of the corresponding message type

### Methods

**as.character** signature(`x = "Descriptor"`): returns the debug string of the descriptor. This is retrieved by a call to the `DebugString` method of the `Descriptor` object.

**toString** signature(`x = "Descriptor"`): same as `as.character`

**\$** signature(`x = "Descriptor"`): retrieves a descriptor for a member of the message type. This can either be another "Descriptor" instance describing a nested type, or a [EnumDescriptor](#) object describing an enum type, or a [FieldDescriptor](#) object describing a field of the message

**new** signature(Class = "Descriptor"): creates a prototype message ([Message](#)) of this descriptor

**show** signature(object = "Descriptor"): simple information

**containing\_type** signature(object = "Descriptor") : returns a descriptor of the message type that contains this message descriptor, or NULL if this is a top-level message type.

**field\_count** signature(object = "Descriptor") : The number of fields of this message type.

**nested\_type\_count** signature(object = "Descriptor") : The number of nested types of this message type.

**enum\_type\_count** signature(object = "Descriptor") : The number of enum types of this message type.

**field** signature(object = "Descriptor") : extract a field descriptor from a descriptor. Exactly one argument of index, number or name has to be used. If index is used, the field descriptor is retrieved by position, using the field method of the google::protobuf::Descriptor C++ class. If number is used, the field descriptor is retrieved using the tag number, with the FindFieldByNumber C++ method. If name is used, the field descriptor is retrieved by name using the FindFieldByName

**nested\_type** signature(object = "Descriptor") : extracts a message type descriptor that is nested in this descriptor. Exactly one argument of index of name has to be used. If index is used, the nested type will be retrieved using its position with the nested\_type method of the google::protobuf::Descriptor C++ class. If name is used, the nested type will be retrieved using its name, with the FindNestedTypeByName C++ method

**enum\_type** signature(object = "Descriptor") : extracts an enum type descriptor that is contained in this descriptor. Exactly one argument of index of name has to be used. If index is used, the enum type will be retrieved using its position with the enum\_type method of the google::protobuf::Descriptor C++ class. If name is used, the enum type will be retrieved using its name, with the FindEnumTypeByName C++ method

**[[** signature(x = "Descriptor"): extracts a field identified by its name or declared tag number

**names** signature(x = "Descriptor") : extracts names of this descriptor

**length** signature(x = "Descriptor") : extracts length of this descriptor

**Author(s)**

Romain Francois <francoisromain@free.fr>

**References**

The Descriptor c++ class. <http://code.google.com/apis/protocolbuffers/docs/reference/cpp/google.protobuf.descriptor.html#Descriptor>

**See Also**

the [P](#) function creates "Descriptor" messages.

**Examples**

```
## Not run:
# example proto file supplied with this package
proto.file <- system.file( "proto", "addressbook.proto", package = "RProtoBuf" )
# reading a proto file and creating the descriptor
Person <- P( "tutorial.Person", file = proto.file )

## End(Not run)

# enum type
Person$PhoneType

# nested type
Person$PhoneNumber

# field
Person$email

# use this descriptor to create a message
new( Person )
```

---

descriptor-methods     *Get the descriptor of a message*

---

**Description**

Get the [Descriptor](#) associated with a [Message](#)

**Methods**

signature(object = "Message") Get the descriptor of the message, as a [Descriptor](#) instance

---

EnumDescriptor-class     *Class "EnumDescriptor"*

---

**Description**

R representation of an enum descriptor. This is a thin wrapper around the EnumDescriptor c++ class.

**Objects from the Class**

Objects of this class are typically retrieved as members of [Descriptor](#) objects

**Slots**

**pointer:** external pointer to the EnumDescriptor instance  
**name:** simple name of the enum  
**full\_name:** fully qualified name  
**type:** fully qualified name of the type that contains this enumeration

**Methods**

**show** signature(object = "EnumDescriptor"): small information  
**as.character** signature(x = "EnumDescriptor"): returns the debug string of the enum descriptor. This is retrieved by a call to the DebugString method of the EnumDescriptor object.  
**toString** signature(x = "EnumDescriptor"): same as as.character  
**\$** signature(x = "EnumDescriptor"): get the number associated with the name  
**has** signature(object = "EnumDescriptor"): indicate if the given name is a constant present in this enum.  
**containing\_type** signature(object = "EnumDescriptor"): returns a [Descriptor](#) of the message type that contains this enum descriptor, or NULL if this is a top level enum descriptor.  
**length** signature(x = "EnumDescriptor"): number of constants in this enum.  
**value\_count** signature(object = "EnumDescriptor"): number of constants in this enum.  
**value** signature(object = "EnumDescriptor"): extracts an [EnumValueDescriptor](#). Exactly one argument of index, number or name has to be used. If index is used, the enum value descriptor is retrieved by position, using the value method of the C++ class. If number is used, the enum value descriptor is retrieved using the value of the constant, using the FindValueByNumber C++ method. If name is used, the enum value descriptor is retrieved using the name of the constant, using the FindValueByName C++ method.  
**[[** signature(x = "EnumDescriptor"): extracts field identified by its name or declared tag number  
**names** signature(x = "EnumDescriptor"): extracts names of this enum

**Author(s)**

Romain Francois <francoisromain@free.fr>

**References**

The EnumDescriptor C++ class

**See Also**

The [Descriptor](#) class

**Examples**

```
## Not run:
# example proto file supplied with this package
proto.file <- system.file( "proto", "addressbook.proto", package = "RProtoBuf" )

# reading a proto file and creating the descriptor
Person <- P( "tutorial.Person", file = proto.file )

## End(Not run)

# enum type
Person$PhoneType

has(Person$PhoneType, "MOBILE")
has(Person$PhoneType, "HOME")
has(Person$PhoneType, "WORK")

has(Person$PhoneType, "FOOBAR")

length(Person$PhoneType)
```

---

EnumValueDescriptor-class

*Class "EnumValueDescriptor"*

---

**Description**

R representation of an enum value descriptor. This is a thin wrapper around the EnumValueDescriptor c++ class.

**Objects from the Class**

Objects of this class are typically retrieved with the value method of the [EnumDescriptor](#) class

**Slots**

**pointer:** external pointer to the EnumValueDescriptor instance  
**name:** simple name of the enum  
**full\_name:** fully qualified name

**Methods**

**show** signature(object = "EnumValueDescriptor"): small information  
**as.character** signature(x = "EnumValueDescriptor"): returns the debug string of the enum descriptor. This is retrieved by a call to the DebugString method of the EnumDescriptor object.  
**toString** signature(x = "EnumValueDescriptor"): same as as.character  
**\$** signature(x = "EnumValueDescriptor"): invoke pseudo methods

**name** signature(object = "EnumValueDescriptor", full = "logical"): return the name of this enum constant.

**number** signature(object = "EnumValueDescriptor"): return the numeric value of this enum constant.

**enum\_type** signature(object = "EnumDescriptor") : retrieves the [EnumDescriptor](#) related to this value descriptor.

---

### Description

R representation of message type field descriptor. This is a thin wrapper around the C++ class FieldDescriptor

### Objects from the Class

Objects typically are retrieved from [FieldDescriptor](#)

### Slots

**pointer:** external pointer to the FieldDescriptor c++ object  
**name:** name of the field within the message type  
**full\_name:** Fully qualified name of the field  
**type:** Fully qualified name of the type that contains this field

### Methods

**show** signature(object = "FieldDescriptor"): small description  
**as.character** signature(x = "FieldDescriptor"): returns the debug string of the field descriptor. This is retrieved by a call to the DebugString method of the FieldDescriptor object.  
**toString** signature(x = "FieldDescriptor"): same as as.character  
**\$** signature(x = "FieldDescriptor"): used to invoke pseudo methods  
**containing\_type** signature(object = "FieldDescriptor") : returns a [Descriptor](#) of the message type that contains this field descriptor.  
**is\_extension** signature(object = "FieldDescriptor") : indicates if this is an extension.  
**number** signature(object = "FieldDescriptor") : gets the declared tag number of this field.  
**type** signature(object = "FieldDescriptor") : type of this field.  
**cpp\_type** signature(object = "FieldDescriptor") : c++ type of this field.  
**label** signature(object = "FieldDescriptor") : label of this field.  
**is\_required** signature(object = "FieldDescriptor") : is this field required.  
**is\_optional** signature(object = "FieldDescriptor") : is this field optional.  
**is\_repeated** signature(object = "FieldDescriptor") : is this field repeated.  
**has\_default\_value** signature(object = "FieldDescriptor") : indicates if this field has a default value.  
**default\_value** signature(object = "FieldDescriptor") : the default value of this field.  
**message\_type** signature(object = "FieldDescriptor") : the [Descriptor](#) for the associated message type. Generates an error if this field is not a message type field.  
**enum\_type** signature(object = "FieldDescriptor") : the [EnumDescriptor](#) for the associated enum type. Generates an error if this field is not an enum type field

---

FileDescriptor-class    *Class "FileDescriptor"*

---

### Description

Class "FileDescriptor"

### Objects from the Class

Objects are usually created using the [fileDescriptor](#) method

### Slots

**pointer:** external pointer to a google::protobuf::FileDescriptor C++ object

**package:** the package name defined in the file, e.g. 'tutorial'.

**filename:** the filename of this FileDescriptor

### Methods

**\$** signature(x = "FileDescriptor"): used to invoke a pseudo method of the file descriptor or get a top level message, enum or service descriptor

**toString** signature(x = "FileDescriptor" ) : gets the debug string

**as.character** signature(x = "FileDescriptor" ) : gets the debug string

**show** signature(x = "FileDescriptor" ) : prints small text

**name** signature(object = "FileDescriptor" ) : name of the file

### Examples

```
# example proto file supplied with this package
desc <- P("tutorial.Person")
person <- new(desc)

person$fileDescriptor()
name(person$fileDescriptor())
# [1] "addressbook.proto"
as.character(person$fileDescriptor())
```

---

fileDescriptor-methods

*gets the file descriptor of an object*

---

### Description

Gets the file descriptor of an object

### Methods

signature(object = "Descriptor") retrieves the file descriptor associated with this descriptor

signature(object = "Message") retrieves the file descriptor associated with the descriptor of this message

signature(object = "EnumDescriptor") retrieves the file descriptor associated with the enum descriptor

signature(object = "FieldDescriptor") retrieves the file descriptor associated with the field descriptor

signature(object = "ServiceDescriptor") retrieves the file descriptor associated with the service descriptor

signature(object = "MethodDescriptor") retrieves the file descriptor associated with the method descriptor

---

FileInputStream-class *Class "FileInputStream"*

---

### Description

A [ZeroCopyInputStream](#) reading from a file

### Objects from the Class

Objects can be created by the [FileInputStream](#) function

**Slots**

pointer: External pointer to the google::protobuf::io::FileInputStream C++ object

**Extends**

Class "[ZeroCopyInputStream](#)", directly.

**Methods**

**close** signature(con="FileInputStream"): Flushes any buffers and closes the underlying file. Returns false if an error occurs during the process; use GetErrno to examine the error

**GetErrno** signature(object="FileInputStream"): If an I/O error has occurred on this file descriptor, this is the errno from that error. Otherwise, this is zero. Once an error occurs, the stream is broken and all subsequent operations will fail.

**SetCloseOnDelete** signature(object="FileInputStream"): set the close on delete behavior.

See [ZeroCopyInputStream](#) for inherited methods

**Author(s)**

Romain Francois <francoisromain@free.fr>

**References**

The FileInputStream class from the protobuf C++ library. FileInputStream-methods

*Creates an FileInputStream*

---

**Description**

Constructor for [FileInputStream](#) objects

**Methods**

signature(filename = "character", block\_size = "logical", close.on.delete = "logical" )  
Creates a [FileInputStream](#) reading from the given file.

---

FileOutputStream-class

*Class "FileOutputStream"*

---

### Description

A [ZeroCopyOutputStream](#) reading from a file

### Objects from the Class

Objects can be created by the [FileOutputStream](#) function

### Slots

**pointer:** External pointer to the `google::protobuf::io::FileOutputStream` C++ object

### Extends

Class "[ZeroCopyOutputStream](#)", directly.

### Methods

**close** signature(`con="FileOutputStream"`): Flushes any buffers and closes the underlying file. Returns false if an error occurs during the process; use `GetErrno` to examine the error

**flush** signature(`con="FileOutputStream"`): Flushes `FileOutputStream`'s buffers but does not close the underlying file

**GetErrno** signature(`object="FileInputStream"`): If an I/O error has occurred on this file descriptor, this is the `errno` from that error. Otherwise, this is zero. Once an error occurs, the stream is broken and all subsequent operations will fail.

**SetCloseOnDelete** signature(`object="FileOutputStream"`): set the close on delete behavior. See [ZeroCopyOutputStream](#) for inherited methods

*Creates an FileOutputStream*

---

### Description

Constructor for [FileOutputStream](#) objects

### Methods

signature(filename = "character", block\_size = "logical", close.on.delete = "logical" )  
 Creates a [FileOutputStream](#) writing to the given file.

---

 GetErrno-methods

*Get the error number for an I/O error*

---

### Description

If an I/O error has occurred on this file descriptor, this is the errno from that error

### Methods

See classes [FileInputStream](#) and [FileOutputStream](#) for implementations.

---

 has-methods

*Indicates if an object has the given field set*

---

### Description

This generic method, currently implemented for [Message](#) and [EnumDescriptor](#) indicates if the message or enum descriptor has the given field set.

For messages and non-repeated fields, a call to the `HasField` method of the corresponding `Message` is issued.

For messages and repeated fields, a call to the `FieldSize` method is issued, and the message is declared to have the field if the size is greater than 0.

NULL is returned if the descriptor for the message does not contain the given field at all.

For `EnumDescriptors`, a boolean value indicates if the given name is present in the enum definition.

### Methods

**has** signature(object = "Message"): Indicates if the message has a given field.

**has** signature(object = "EnumDescriptor"): Indicates if the `EnumDescriptor` has a given named element.

**Examples**

```

unittest.proto.file <- system.file("tinytest", "data", "unittest.proto",
  package = "RProtoBuf" )
readProtoFiles(file = unittest.proto.file)

test <- new(protoBuf_unittest.TestAllTypes)
test$has("optional_int32")
# FALSE
test$add("repeated_int32", 1:10)
test$has("repeated_int32")
# TRUE
test$has("nonexistent")
# NULL

has(protoBuf_unittest.TestAllTypes$NestedEnum, "FOO")
has(protoBuf_unittest.TestAllTypes$NestedEnum, "BAR")
has(protoBuf_unittest.TestAllTypes$NestedEnum, "XXX")

```

---

invoke-methods	<i>invoke a protobuf rpc method</i>
----------------	-------------------------------------

---

**Description**

invoke a protobuf rpc method

**Methods**

signature(method = "MethodDescriptor", message = "Message") invoke a protobuf rpc method locally.

signature(method = "MethodDescriptor", message = "Message", protocol = "RpcHTTP" ) invoke a protobuf rpc method over http.

---

isInitialized-methods	<i>Indicates if a protocol buffer message is initialized</i>
-----------------------	--

---

**Description**

Indicates if a [Message](#) is initialized. A message is initialized if all its required fields are set.

**Methods**

signature(object = "Message") is the message initialized

**Examples**

```

message <- new( tutorial.Person, name = "" )
isInitialized( message ) # FALSE (id is not set)
message$isInitialized() # FALSE

message <- new( tutorial.Person, name = "", id = 2 )
isInitialized( message ) # TRUE
message$isInitialized() # TRUE

```

---

is\_extension-methods    *Indicates if a field descriptor is an extension*

---

**Description**

Indicates if a field descriptor is an extension

**See Also**

The method is implemented for the [FieldDescriptor](#) class

**Examples**

```

Person <- P( "tutorial.Person" )
is_extension(Person$id)

```

---

label-methods    *Gets the label of a field*

---

**Description**

Gets the label of a field (optional, required, or repeated).

**Arguments**

object	A <a href="#">FieldDescriptor</a> object.
as.string	If true, print a string representation of the type.

**See Also**

The method is implemented for the [FieldDescriptor](#) class

## Examples

```
## Not run:
proto.file <- system.file( "proto", "addressbook.proto", package = "RProtoBuf" )
Person <- P( "tutorial.Person", file = proto.file )

## End(Not run)

label(Person$id)
label(Person$email)
label(Person$phone)
label(Person$id, TRUE)
label(Person$email, TRUE)
label(Person$phone, TRUE)
LABEL_OPTIONAL
LABEL_REQUIRED
LABEL_REPEATED
```

---

merge-methods

*Merge two messages of the same type*

---

## Description

Merge two [Message](#) objects of the same type.

## Methods

signature(x = "Message", y = "Message") merge two messages of the same type

## Errors

An error of class "IncompatibleType" is thrown if the two messages are not of the same message type.

## Examples

```
m1 <- new( tutorial.Person, email = "francoisromain@free.fr" )
m2 <- new( tutorial.Person, id = 5 )
m3 <- merge( m1, m2 )
writeLines( as.character( m1 ) )
writeLines( as.character( m2 ) )
writeLines( as.character( m3 ) )
```

---

 Message-class

 Class "Message"
 

---

### Description

R representation of protocol buffer messages. This is a thin wrapper around the Message c++ class that holds the actual message as an external pointer.

### Objects from the Class

Objects are typically created by the new function invoked on a [Descriptor](#) object.

### Slots

pointer: external pointer to the c++ Message object

type: fully qualified name of the message type

### Methods

**as.character** signature(x = "Message"): returns the debug string of the message. This is built from a call to the DebugString method of the Message object

**toString** signature(x = "Message"): same as as.character

**toJSON** signature(x = "Message"): returns the JSON representation of the message. This is built from a call to the google::protobuf::util::MessageToJsonString method

**\$<** signature(x = "Message"): set the value of a field of the message.

**\$** signature(x = "Message"): gets the value of a field. Primitive types are brought back to R as R objects of the closest matching R type. Messages are brought back as instances of the Message class.

**[[** signature(x = "Message"): extracts a field identified by its name or declared tag number

**[[<** signature(x = "Message"): replace the value of a field identified by its name or declared tag number

**serialize** signature(object = "Message"): serialize a message. If the "connection" argument is NULL, the payload of the message is returned as a raw vector, if the "connection" argument is a binary writable connection, the payload is written into the connection. If "connection" is a character vector, the message is sent to the file (in binary format).

**show** signature(object = "Message"): displays a short text about the message

**update** signature(object = "Message"): set several fields of the message at once

**length** signature(x = "Message"): The number of fields actually contained in the message. A field counts in these two situations: the field is repeated and the field size is greater than 0, the field is not repeated and the message has the field.

**setExtension** signature(object = "Message"): set an extension field of the Message.

**getExtension** signature(object = "Message"): get the value of an extension field of the Message.

**str** signature(object = "Message"): displays the structure of the message  
**identical** signature(x = "Message", y = "Message"): Test if two messages are exactly identical  
**==** signature(e1 = "Message", e2 = "Message"): Same as identical  
**!=** signature(e1 = "Message", e2 = "Message"): Negation of identical  
**all.equal** signature(e1 = "Message", e2 = "Message"): Test near equality  
**names** signature(x = "Message"): extracts the names of the message.

**Author(s)**

Romain Francois <francoisromain@free.fr>

**References**

The Message class from the C++ proto library. <http://code.google.com/apis/protocolbuffers/docs/reference/cpp/google.protobuf.message.html>

**See Also**

**P** creates objects of class **Descriptor** that can be used to create messages.

**Examples**

```
## Not run:
# example proto file supplied with this package
proto.file <- system.file( "proto", "addressbook.proto", package = "RProtoBuf" )

# reading a proto file and creating the descriptor
Person <- P( "tutorial.Person", file = proto.file )

## End(Not run)

PhoneNumber <- P( "tutorial.Person.PhoneNumber" )

# creating a prototype message from the descriptor
p <- new( Person )
p$email # not set, returns default value
p$id    # not set, returns default value
as.character( p ) # empty
has( p, "email" ) # is the "email" field set
has( p, "phone" ) # is the "email" field set
length( p )      # number of fields actually set

# update several fields at once
romain <- update( new( Person ),
  email = "francoisromain@free.fr",
  id = 1,
  name = "Romain Francois",
  phone = new( PhoneNumber , number = "+33(0)...", type = "MOBILE" )
)
```

```

# supply parameters to the constructor
dirk <- new( Person,
  email = "edd@debian.org",
  id = 2,
  name = "Dirk Eddelbuettel" )
# update the phone repeated field with a list of PhoneNumber messages
dirk$phone <- list(
  new( PhoneNumber , number = "+01...", type = "MOBILE" ),
  new( PhoneNumber , number = "+01...", type = "HOME" ) )

# with/within style
saptarshi <- within( new(Person), {
  id <- 3
  name <- "Saptarshi Guha"
  email <- "saptarshi.guha@gmail.com"
} )

# make an addressbook
book <- new( tutorial.AddressBook, person = list( romain, dirk, saptarshi ) )

# serialize the message to a file
tf <- tempfile( )
serialize( book, tf )

# the payload of the message
serialize( book, NULL )

# read the file into a new message
m <- tutorial.AddressBook$read( tf )
writeLines( as.character( m ) )
sapply( m$person, function(p) p$name )

```

---

MethodDescriptor-class

*Class "MethodDescriptor"*

---

## Description

R representation of Service Descriptors

## Objects from the Class

TODO

## Slots

**pointer:** External pointer to a google::protobuf::MethodDescriptor C++ object

**name:** fully qualified name of the method

**service:** fully qualified name of the service that defines this method

**Methods**

**as.character** signature(x = "MethodDescriptor"): debug string of the method  
**toString** signature(x = "MethodDescriptor"): debug string of the method  
**\$** signature(x = "MethodDescriptor"): ...  
**\$<-** signature(x = "MethodDescriptor"): ...  
**input\_type** signature(object = "MethodDescriptor"): the [Descriptor](#) of the input type of the method  
**output\_type** signature(object = "MethodDescriptor"): the [Descriptor](#) of the output type of the method

### Description

Obtains a chunk of data from the stream

### See Also

[ZeroCopyInputStream](#) implements Next.

---

number-methods

*Gets the declared tag number of a field*

---

### Description

Gets the declared tag number of a field

### See Also

The method is implemented for [FieldDescriptor](#) and [EnumValueDescriptor](#) classes.

### Examples

```
## Not run:
proto.file <- system.file( "proto", "addressbook.proto", package = "RProtoBuf" )
Person <- P( "tutorial.Person", file = proto.file )
```

```
## End(Not run)
```

```
number(Person$id)
number(Person$email)
as.character(Person)
```

```
number(value(tutorial.Person$PhoneType, name="HOME"))
```

---

P *Protocol Buffer descriptor importer*

---

### Description

The P function searches for a protocol message descriptor in the descriptor pool.

### Usage

P(type, file)

### Arguments

type	Fully qualified type name of the protocol buffer or extension
file	optional proto file. If given, the definition contained in the file is first registered with the pool of message descriptors

### Value

An object of class [Descriptor](#) for message types or [FieldDescriptor](#) for extensions. An error is generated otherwise.

### Author(s)

Romain Francois <francoisromain@free.fr>

### Examples

```
## Not run:
proto.file <- system.file( "proto", "addressbook.proto", package = "RProtoBuf" )
Person <- P( "tutorial.Person", file = proto.file )

## End(Not run)

cat(as.character( Person ))
```

---

read-methods *Read a protocol buffer message from a connection*

---

### Description

Read a [Message](#) from a connection using its associated [Descriptor](#)

**Methods**

signature(descriptor = "Descriptor", input = "character") Read the message from a file  
signature(descriptor = "Descriptor") Read from a binary connection.  
signature(descriptor = "Descriptor", input = "raw") Read the message from a raw vector

**Examples**

```
# example file that contains a "tutorial.AddressBook" message
book <- system.file( "examples", "addressbook.pb", package = "RProtoBuf" )

# read the message
message <- read( tutorial.AddressBook, book )

# or using the pseudo method
message <- tutorial.AddressBook$read( book )

# write its debug string
writeLines( as.character( message ) )

# grab the name of each person
sapply( message$person, function(p) p$name )

# read from a binary file connection
f <- file( book, open = "rb" )
message2 <- read( tutorial.AddressBook, f )
close( f )

# read from a message payload (raw vector)
payload <- readBin( book, raw(0), 5000 )
message3 <- tutorial.AddressBook$read( payload )
```

---

readASCII-methods      *read a message in ASCII format*

---

**Description**

Method to read a Message in ASCII format

**Methods**

signature(descriptor = "Descriptor", input = "ANY") Read the message from a connection  
(file, etc ...)  
signature(descriptor = "Descriptor", input = "character") Read the message directly from  
the character string

**Examples**

```
## Not run:
# example file that contains a "tutorial.AddressBook" message
book <- system.file( "examples", "addressbook.pb", package = "RProtoBuf" )

# read the message
message <- read( tutorial.AddressBook, book )

# Output in text format to a temporary file
out.file <- tempfile()
writeLines( as.character(message), file(out.file))

# Verify that we can read back in the message from a text file.
message2 <- readASCII( tutorial.AddressBook, file(out.file, "rb"))

# Verify that we can read back in the message from an unopened file.
message3 <- readASCII( tutorial.AddressBook, file(out.file))

\dontshow{
stopifnot( identical( message, message2) )
}

## End(Not run)
```

---

readJSON-methods	<i>read a message in JSON format</i>
------------------	--------------------------------------

---

**Description**

Method to read a Message in JSON format

**Methods**

signature(descriptor = "Descriptor", input = "ANY") Read the message from a connection (file, etc ...)

signature(descriptor = "Descriptor", input = "character") Read the message directly from the character string

**Examples**

```
## Not run:
# example file that contains a "tutorial.AddressBook" message
book <- system.file( "examples", "addressbook.pb", package = "RProtoBuf" )

# read the message
message <- read( tutorial.AddressBook, book )

# Output in text format to a temporary file
out.file <- tempfile()
```

```

writeLines( message$toJSON(), file(out.file))

# Verify that we can read back in the message from a text file.
message2 <- readJSON( tutorial.AddressBook, file(out.file, "rb"))

# Verify that we can read back in the message from an unopened file.
message3 <- readJSON( tutorial.AddressBook, file(out.file))

\dontshow{
stopifnot( identical( message, message2) )
}

## End(Not run)

```

---

readProtoFiles	<i>protocol buffer descriptor importer</i>
----------------	--

---

## Description

Imports proto files into the descriptor pool that is then used by the P function to resolve message type names.

## Usage

```

readProtoFiles(files, dir, package="RProtoBuf", pattern="\\.proto$", lib.loc=NULL)
readProtoFiles2(files, dir=".", pattern="\\.proto$", recursive=FALSE, protoPath=getwd())
resetDescriptorPool()

```

## Arguments

files	Proto files
dir	Directory. If files is not specified, files with the "proto" extension in the dir directory are imported
package	R package name. If files and dir are missing, "proto" files in the "proto" directory of the package tree are imported.
pattern	A filename pattern to match proto files when using dir.
recursive	Whether to descend recursively into dir.
lib.loc	Library location.
protoPath	Search path for proto file imports.

## Details

readProtoFiles2 is different from readProtoFiles to be consistent with the behavior of protoc command line tool in being explicit about the search path for proto import statements. In addition, we also require that both files and dir arguments are interpreted relative to protoPath, so that there is consistency in future imports of the same files through import statements of other proto files.

resetDescriptorPool clears all imported proto definitions.

**Value**

NULL, invisibly.

**Author(s)**

Romain Francois <francoisromain@free.fr>

**See Also**

[P](#)

**Examples**

```
## Not run:
# from a package
readProtoFiles(package = "RProtoBuf")

# from a directory
proto.dir <- system.file("proto", package = "RProtoBuf")
readProtoFiles(dir = proto.dir)

# set of files
proto.files <- list.files(proto.dir, full.names = TRUE)
readProtoFiles(proto.files)

## End(Not run)
```

---

RpcHTTP-class

*Class "RpcHTTP"*

---

**Description**

Support for protobuf rpc over HTTP

**Objects from the Class**

Objects can be created by calls of the form `new("RpcHTTP", host = "somehost", port = port.number, root = "" )`

**Slots**

**host:** Host name

**port:** port number

**root:** root directory of the protobuf http server

**Author(s)**

Romain Francois <francoisromain@free.fr>

**See Also**

[invoke](#) uses objects of this class to perform a method invocation over http.

---

serialize\_pb

*Serialize R object to Protocol Buffer Message.*

---

**Description**

Serializes R objects to a general purpose protobuf message using the same `rexp.proto` descriptor and mapping between R objects and protobuf messages as RHIPE.

**Usage**

```
serialize_pb(object, connection, ...)
```

**Arguments**

<code>object</code>	R object to serialize
<code>connection</code>	passed on to <a href="#">serialize</a>
<code>...</code>	additional arguments passed on to <a href="#">serialize</a>

**Details**

Clients need both the message and the `rexp.proto` descriptor to parse serialized R objects. The latter is included in the the package installation proto directory: `system.file(package="RProtoBuf", "proto/rexp.proto"`

The following storage types are natively supported by the descriptor: `character`, `raw`, `double`, `complex`, `integer`, `list`, and `NULL`. Objects with other storage types, such as functions, environments, S4 classes, etc, are serialized using base R [serialize](#) and stored in the proto native type. Missing values, attributes and numeric precision will be preserved.

**Examples**

```
msg <- tempfile();
serialize_pb(iris, msg);
obj <- unserialize_pb(msg);
identical(iris, obj);
```

---

ServiceDescriptor-class  
*Class "ServiceDescriptor"*

---

**Description**

R representation of Service Descriptors

**Objects from the Class**

TODO

**Slots**

**pointer:** External pointer to a google::protobuf::ServiceDescriptor C++ object

**name:** fully qualified name of the service

**Methods**

**as.character** signature(x = "ServiceDescriptor"): debug string of the service

**toString** signature(x = "ServiceDescriptor"): debug string of the service

**show** signature(x = "ServiceDescriptor"): ...

**\$** signature(x = "ServiceDescriptor"): invoke pseudo methods or retrieve method descriptors contained in this service descriptor.

**[[** signature(x = "ServiceDescriptor"): extracts methods descriptors contained in this service descriptor

**length** signature(x = "ServiceDescriptor"): number of [MethodDescriptor](#)

**method\_count** signature(x = "ServiceDescriptor"): number of [MethodDescriptor](#)

**method** signature(x = "ServiceDescriptor"): retrieves a [MethodDescriptor](#)

**Author(s)**

Romain Francois <francoisromain@free.fr>

---

set-methods                      *set a subset of values of a repeated field of a message*

---

**Description**

set a subset of values of a repeated field of a message

**Methods**

signature(object = "Message") set a subset of values of a repeated field of a message

---

 SetCloseOnDelete-methods

*set the close on delete behavior*

---

### Description

By default, the file descriptor is not closed when a stream is destroyed, use `SetCloseOnDelete(stream, TRUE)` to change that.

### Methods

See classes [FileInputStream](#) and [FileOutputStream](#) for implementations.

---

size-methods

*Size of a message field*

---

### Description

The number of object currently in a given field of a protocol buffer message.

For non repeated fields, the size is 1 if the message has the field, 0 otherwise.

For repeated fields, the size is the number of objects in the array.

For repeated fields, the size can also be assigned to in order to shrink or grow the vector. Numeric types are given a default value of 0 when the new size is greater than the existing size. Character types are given a default value of "". Growing a repeated field in this way is not supported for message, group, and enum types.

### Methods

`signature(object = "Message")` Number of objects in a message field

### Examples

```

unitest.proto.file <- system.file("tinytest", "data", "unitest.proto",
  package = "RProtoBuf" )
readProtoFiles(file = unitest.proto.file)

test <- new(protobuf_unitest.TestAllTypes)
test$size("optional_int32")

test$add("repeated_int32", 1:10)
test$size("repeated_int32")
test$repeated_int32

size(test, "repeated_int32") <- 5
test$repeated_int32

```

```
size(test, "repeated_int32") <- 15
test$repeated_int32
```

---

sizegets	<i>Set the size of a field</i>
----------	--------------------------------

---

### Description

Sets the size of a repeated field.

### Methods

signature(object = "Message") sets the size of a message field

---

Skip-methods	<i>Skips a number of bytes</i>
--------------	--------------------------------

---

### Description

Skips a number of bytes

---

swap-methods	<i>swap elements of a repeated field of a message</i>
--------------	---

---

### Description

swap elements of a repeated field of a message.

### Methods

signature(object = "Message") swap elements of a repeated field of a message

### References

See the SwapElements of the Reflection class, part of the protobuf library. <http://code.google.com/apis/protocolbuffers/docs/reference/cpp/google.protobuf.message.html>

---

type-methods	<i>Gets the type or the C++ type of a field</i>
--------------	---

---

**Description**

Gets the type or the C++ type of a field

**Arguments**

object	A <a href="#">FieldDescriptor</a> object.
as.string	If true, print a string representation of the type.

**See Also**

The method is implemented for the [FieldDescriptor](#) class

**Examples**

```
## Not run:
proto.file <- system.file( "proto", "addressbook.proto", package = "RProtoBuf" )
Person <- P( "tutorial.Person", file = proto.file )

## End(Not run)

type(Person$id)
type(Person$id, as.string=TRUE)
cpp_type(Person$email)
cpp_type(Person$email, TRUE)
```

---

with.Message	<i>with and within methods for protocol buffer messages</i>
--------------	---

---

**Description**

Convenience wrapper that allow getting and setting fields of protocol buffer messages from within the object

**Usage**

```
## S3 method for class 'Message'
with(data, expr, ...)
## S3 method for class 'Message'
within(data, expr, ...)
```

**Arguments**

data	A protocol buffer message, instance of <a href="#">Message</a>
expr	R expression to evaluate
...	ignored

**Details**

The expression is evaluated in an environment that allows to set and get fields of the message

The fields of the message are mapped to active bindings (see [makeActiveBinding](#)) so that they can be accessed and modified from within the environment.

**Value**

with returns the value of the expression and within returns the data argument.

**Author(s)**

Romain Francois <francoisromain@free.fr>

**Examples**

```
## Not run:
proto.file <- system.file( "proto", "addressbook.proto", package = "RProtoBuf" )
Person <- P( "tutorial.Person", file = proto.file )

## End(Not run)

romain <- within( new( Person ), {
  email <- "francoisromain@free.fr"
  id <- 10L
} )
```

---

ZeroCopyInputStream-class

*Virtual Class "ZeroCopyInputStream"*

---

**Description**

R wrapper for the ZeroCopyInputStream c++ class

**Objects from the Class**

This is a virtual class

**Slots**

pointer: external pointer to the google::protobuf::io::ZeroCopyInputStream object

**Methods**

- \$** signature(x="ZeroCopyInputStream"): invokes a method
- Next** signature(object="ZeroCopyInputStream"): Get a number of bytes from the stream as a raw vector.
- Skip** signature(object="ZeroCopyInputStream"): skip a number of bytes
- BackUp** signature(object="ZeroCopyInputStream"): Backs up a number of bytes, so that the next call to Next returns data again that was already returned by the last call to Next.
- ByteCount** signature(object="ZeroCopyInputStream"): Returns the total number of bytes read since this object was created.
- ReadRaw** signature(object="ZeroCopyInputStream", size = "integer"): read raw bytes from the stream
- ReadRaw** signature(object="ZeroCopyInputStream", size = "numeric"): read raw bytes from the stream
- ReadString** signature(object="ZeroCopyInputStream", size = "integer"): same as ReadRaw but formats the result as a string
- ReadString** signature(object="ZeroCopyInputStream", size = "numeric"): same as ReadRaw but formats the result as a string
- ReadVarint32** signature(object="ZeroCopyInputStream"): Read an unsigned integer with Varint encoding, truncating to 32 bits.
- ReadLittleEndian32** signature(object="ZeroCopyInputStream"): Read a 32-bit little-endian integer.
- ReadLittleEndian64** signature(object="ZeroCopyInputStream"): Read a 64-bit little-endian integer. In R the value is stored as a double which loses some precision (no other way)
- ReadVarint64** signature(object="ZeroCopyInputStream"): Read a 64-bit integer with varint encoding. In R the value is stored as a double which loses some precision (no other way)

**Author(s)**

Romain Francois <francoisromain@free.fr>

**References**

---

ZeroCopyOutputStream-class

*Virtual Class "ZeroCopyOutputStream"*

---

### Description

R wrapper for the ZeroCopyOutputStream c++ class

### Objects from the Class

This is a virtual class

### Slots

**pointer:** external pointer to the google::protobuf::io::ZeroCopyOutputStream object

### Methods

**\$** signature(x="ZeroCopyOutputStream"): invokes a method

**Next** signature(object="ZeroCopyOutputStream", payload = "raw" ): push the raw vector into the stream. Returns the number of bytes actually written.

**BackUp** signature(object="ZeroCopyOutputStream"): Backs up a number of bytes, so that the end of the last buffer returned by Next is not actually written.

**ByteCount** signature(object="ZeroCopyOutputStream"): Returns the total number of bytes written since this object was created.

**WriteRaw** signature(object="ZeroCopyOutputStream", payload = "raw"): write the raw bytes to the stream

### Author(s)

Romain Francois <francoisromain@free.fr>
