Example Session for Supervised Classification

Andreas Borg, Murat Sariyar
August 24, 2020

This document shows an example session for using supervised classification in the package `RecordLinkage` for deduplication of a single data set. Conducting linkage of two data sets differs only in the step of generating record pairs.

See also the vignette on Fellegi-Sunter deduplication for some general information on using the package.

1 Generating comparison patterns

In this session, a training set with 50 matches and 250 non-matches is generated from the included data set `RLData10000`. Record pairs from the set `RLData500` are used to calibrate and subsequently evaluate the classifiers.

```r
data(RLdata500)
data(RLdata10000)
train_pairs=compare.dedup(RLdata10000, identity=identity.RLdata10000, 
n_match=500, n_non_match=500)
eval_pairs=compare.dedup(RLdata500, identity=identity.RLdata500)
```

2 Training

`trainSupv` handles calibration of supervised classifiers which are selected through the argument `method`. In the following, a single decision tree (`rpart`), a bootstrap aggregation of decision trees (bagging) and a support vector machine are calibrated (`svm`).

```r
model_rpart=trainSupv(train_pairs, method="rpart")
model_bagging=trainSupv(train_pairs, method="bagging")
model_svm=trainSupv(train_pairs, method="svm")
```

3 Classification

`classifySupv` handles classification for all supervised classifiers, taking as arguments the structure returned by `trainSupv` which contains the classification model and the set of record pairs which to classify.
result_rpart=classifySupv(model_rpart, eval_pairs)
result_bagging=classifySupv(model_bagging, eval_pairs)
result_svm=classifySupv(model_svm, eval_pairs)

4 Results

4.1 Rpart
alpha error 0.000000
beta error 0.021323
accuracy 0.978685
