Package ‘SpaDES.core’

March 19, 2019

**Type** Package

**Title** Core Utilities for Developing and Running Spatially Explicit Discrete Event Simulation Models

**Description** Provide the core discrete event simulation (DES) framework for implementing spatially explicit simulation models. The core DES components facilitate modularity, and easily enable the user to include additional functionality by running user-built simulation modules. Now includes (experimental) conditional scheduling.

**Date** 2019-03-18

**Version** 0.2.5

**Depends** R (>= 3.3), quickPlot (>= 0.1.4), reproducible (>= 0.2.7)

**Imports** codetools, crayon, data.table (>= 1.10.4), DEoptim (>= 2.2-4), DiagrammeR (>= 0.8.2), dplyr (>= 0.5.0), fastdigest, fpCompare (>= 0.2.1), googledrive, htttr (>= 1.2.1), igraph (>= 1.0.1), lubridate (>= 1.3.3), methods, parallel, RCurl, R.utils (>= 2.5.0), raster (>= 2.5-8), stats, stringi (>= 1.1.3), tcltk, tools, utils

**Suggests** archivist, covr, devtools, knitr, Matrix, magrittr, microbenchmark, png, RandomFields (>= 3.3.4), RColorBrewer (>= 1.1-2), rgdal, rgenoud, sf, SpaDES.tools (>= 0.2.0), rmarkdown, testthat (>= 1.0.2)

**Encoding** UTF-8

**Language** en-CA

**License** GPL-3

**VignetteBuilder** knitr, rmarkdown

**BugReports** [https://github.com/PredictiveEcology/SpaDES.core/issues](https://github.com/PredictiveEcology/SpaDES.core/issues)

**ByteCompile** yes

Description

This package allows implementation a variety of simulation-type models, with a focus on spatially explicit models. The core simulation components are built upon a discrete event simulation framework that facilitates modularity, and easily enables the user to include additional functionality by running user-built simulation modules. Included are numerous tools to visualize various spatial data formats, as well as non-spatial data. Much work has been done to speed up the core of the DES, with current benchmarking as low as 56 microseconds overhead for each event (including scheduling, sorting event queue, spawning event etc.) or 38 microseconds if there is no sorting (i.e., no sorting occurs under simple conditions). Under most event conditions, therefore, the DES itself will contribute very minimally compared to the content of the events, which may often be milliseconds to many seconds each event.

Bug reports: https://github.com/PredictiveEcology/SpaDES.core/issues
1 Spatial discrete event simulation (SpaDES)

A collection of top-level functions for doing spatial discrete event simulation.

1.1 Simulations: There are two workhorse functions that initialize and run a simulation, and third function for doing multiple spades runs:

- `simInit` Initialize a new simulation
- `spades` Run a discrete event simulation
- `experiment` Run multiple `spades` calls

1.2 Events: Within a module, important simulation functions include:

- `scheduleEvent` Schedule a simulation event
- `scheduleConditionalEvent` Schedule a conditional simulation event
- `removeEvent` Remove an event from the simulation queue (not yet implemented)

2 The `simList` object class

The principle exported object class is the `simList`. All SpaDES simulations operate on this object class.

```
simList  The 'simList' class
```

3 `simList` methods

Collections of commonly used functions to retrieve or set slots (and their elements) of a `simList` object are summarized further below.

3.1 Simulation parameters:

- `globals` List of global simulation parameters.
- `params` Nested list of all simulation parameter.
- `P` Namespaced version of `params` (i.e., do not have to specify module name).

3.2 loading from disk, saving to disk:

- `inputs` List of loaded objects used in simulation. (advanced)
- `outputs` List of objects to save during simulation. (advanced)
3.3 objects in the simList:

- **ls.objects** Names of objects referenced by the simulation environment.
- **ls.str** List the structure of the simList objects.
- **objs** List of objects referenced by the simulation environment.

3.4 Simulation paths: Accessor functions for the paths slot and its elements.

- **cachePath** Global simulation cache path.
- **modulePath** Global simulation module path.
- **inputPath** Global simulation input path.
- **outputPath** Global simulation output path.
- **paths** Global simulation paths (cache, modules, inputs, outputs).

3.5 Simulation times: Accessor functions for the simtimes slot and its elements.

- **time** Current simulation time, in units of longest module.
- **start** Simulation start time, in units of longest module.
- **end** Simulation end time, in units of longest module.
- **times** List of all simulation times (current, start, end), in units of longest module.

3.6 Simulation event queues: Accessor functions for the events and completed slots. By default, the event lists are shown when the simList object is printed, thus most users will not require direct use of these methods.

- **events** Scheduled simulation events (the event queue). (advanced)
- **current** Currently executing event. (advanced)
- **completed** Completed simulation events. (advanced)
- **elapsedTime** The amount of clock time that modules & events use

3.7 Modules, dependencies, packages: Accessor functions for the depends, modules, and .loadOrder slots. These are included for advanced users.

- **depends** List of simulation module dependencies. (advanced)
- **modules** List of simulation modules to be loaded. (advanced)
- **packages** Vector of required R libraries of all modules. (advanced)

3.8 simList environment: The simList has a slot called .xData which is an environment. All objects in the simList are actually in this environment, i.e., the simList is not a list. In R, environments use pass-by-reference semantics, which means that copying a simList object using normal R assignment operation (e.g., sim2 <- sim1), will not copy the objects contained within the .xData slot. The two objects (sim1 and sim2) will share identical objects within that slot. Sometimes, this not desired, and a true copy is required.
3.9 Checkpointing:

<table>
<thead>
<tr>
<th>Accessor method</th>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>checkpointFile</td>
<td>.checkpoint</td>
<td>Name of the checkpoint file. (advanced)</td>
</tr>
<tr>
<td>checkpointInterval</td>
<td>.checkpoint</td>
<td>The simulation checkpoint interval. (advanced)</td>
</tr>
</tbody>
</table>

3.10 Progress Bar:

<table>
<thead>
<tr>
<th>Accessor method</th>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>progressType</td>
<td>.progress</td>
<td>Type of graphical progress bar used. (advanced)</td>
</tr>
<tr>
<td>progressInterval</td>
<td>.progress</td>
<td>Interval for the progress bar. (advanced)</td>
</tr>
</tbody>
</table>

4 Module operations

4.1 Creating, distributing, and downloading modules: Modules are the basic unit of SpaDES. These are generally created and stored locally, or are downloaded from remote repositories, including our SpaDES-modules repository on GitHub.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>checksums</td>
<td>Verify (and optionally write) checksums for a module’s data files.</td>
</tr>
<tr>
<td>downloadModule</td>
<td>Open all modules nested within a base directory.</td>
</tr>
<tr>
<td>getModuleVersion</td>
<td>Get the latest module version # from module repository.</td>
</tr>
<tr>
<td>newModule</td>
<td>Create new module from template.</td>
</tr>
<tr>
<td>newModuleDocumentation</td>
<td>Create empty documentation for a new module.</td>
</tr>
<tr>
<td>openModules</td>
<td>Open all modules nested within a base directory.</td>
</tr>
<tr>
<td>moduleMetadata</td>
<td>Shows the module metadata.</td>
</tr>
<tr>
<td>zipModule</td>
<td>Zip a module and its associated files.</td>
</tr>
</tbody>
</table>

4.2 Module metadata: Each module requires several items to be defined. These comprise the metadata for that module (including default parameter specifications, inputs and outputs), and are currently written at the top of the module’s .R file.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>defineModule</td>
<td>Define the module metadata</td>
</tr>
<tr>
<td>defineParameter</td>
<td>Specify a parameter’s name, value and set a default</td>
</tr>
<tr>
<td>expectsInput</td>
<td>Specify an input object’s name, class, description, sourceURL and other specifications</td>
</tr>
<tr>
<td>createsOutput</td>
<td>Specify an output object’s name, class, description and other specifications</td>
</tr>
</tbody>
</table>

There are also accessors for many of the metadata entries:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeunit</td>
<td>Accesses metadata of same name</td>
</tr>
<tr>
<td>citation</td>
<td>Accesses metadata of same name</td>
</tr>
</tbody>
</table>
4.3 Module dependencies: Once a set of modules have been chosen, the dependency information is automatically calculated once simInit is run. There are several functions to assist with dependency information:

- `depsEdgeList` Build edge list for module dependency graph
- `depsGraph` Build a module dependency graph using igraph

5 Module functions

A collection of functions that help with making modules can be found in the suggested SpaDES.tools package, and are summarized below:

5.1 Spatial spreading/distances methods: Spatial contagion is a key phenomenon for spatially explicit simulation models. Contagion can be modelled using discrete approaches or continuous approaches. Several SpaDES.tools functions assist with these:

- `adj` An optimized (i.e., faster) version of `adjacent`
- `cir` Identify pixels in a circle around a `SpatialPoints*` object
- `directionFromEachPoint` Fast calculation of direction and distance surfaces
- `distanceFromEachPoint` Fast calculation of distance surfaces
- `rings` Identify rings around focal cells (e.g., buffers and donuts)
- `spokes` Identify outward radiating spokes from initial points
- `spread` Contagious cellular automata
- `wrap` Create a torus from a grid

5.2 Spatial agent methods: Agents have several methods and functions specific to them:

- `crw` Simple correlated random walk function
- `heading` Determines the heading between `SpatialPoints*`
- `makeLines` Makes `SpatialLines` object for, e.g., drawing arrows
- `move` A meta function that can currently only take "crw"
- `specificNumPerPatch` Initiate a specific number of agents per patch

5.3 GIS operations: In addition to the vast amount of GIS operations available in R (mostly from contributed packages such as `sp`, `raster`, `maps`, `maptools` and many others), we provide the following GIS-related functions:

- `equalExtent` Assess whether a list of extents are all equal
5.4 'Map-reduce’-type operations: These functions convert between reduced and mapped representations of the same data. This allows compact representation of, e.g., rasters that have many individual pixels that share identical information.

\texttt{rasterizeReduced} Convert reduced representation to full raster.

5.5 Colors in \texttt{Raster*} objects: We likely will not want the default colours for every map. Here are several helper functions to add to, set and get colors of \texttt{Raster*} objects:

\begin{itemize}
  \item \texttt{setColors} Set colours for plotting \texttt{Raster*} objects
  \item \texttt{getColors} Get colours in a \texttt{Raster*} objects
  \item \texttt{divergentColors} Create a color palette with diverging colors around a middle
\end{itemize}

5.6 Random Map Generation: It is often useful to build dummy maps with which to build simulation models before all data are available. These dummy maps can later be replaced with actual data maps.

\begin{itemize}
  \item \texttt{gaussMap} Creates a random map using Gaussian random fields
  \item \texttt{randomPolygons} Creates a random polygon with specified number of classes
\end{itemize}

5.7 Checking for the existence of objects: SpaDES modules will often require the existence of objects in the \texttt{simList}. These are helpers for assessing this:

\begin{itemize}
  \item \texttt{checkObject} Check for a existence of an object within a \texttt{simList}
  \item \texttt{checkPath} Checks the specified filepath for formatting consistencies
\end{itemize}

5.8 SELES-type approach to simulation: These functions are essentially skeletons and are not fully implemented. They are intended to make translations from \texttt{SELES}. You must know how to use \texttt{SELES} for these to be useful:

\begin{itemize}
  \item \texttt{agentLocation} Agent location
  \item \texttt{initiateAgents} Initiate agents into a \texttt{SpatialPointsDataFrame}
  \item \texttt{numAgents} Number of agents
  \item \texttt{probInit} Probability of initiating an agent or event
  \item \texttt{transitions} Transition probability
\end{itemize}

5.9 Miscellaneous: Functions that may be useful within a SpaDES context:

\begin{itemize}
  \item \texttt{InRange} Test whether a number lies within range \([a,b]\)
  \item \texttt{layerNames} Get layer names for numerous object classes
  \item \texttt{loadPackages} Simple wrapper for loading packages
  \item \texttt{numLayers} Return number of layers
  \item \texttt{paddedFloatToChar} Wrapper for padding (e.g., zeros) floating numbers to character
  \item \texttt{updateList} Update values in a named list
\end{itemize}
6 Caching simulations and simulation components

Simulation caching uses the reproducible package.

Caching can be done in a variety of ways, most of which are up to the module developer. However, the one most common usage would be to cache a simulation run. This might be useful if a simulation is very long, has been run once, and the goal is just to retrieve final results. This would be an alternative to manually saving the outputs.

See example in spades, achieved by using cache = TRUE argument.

<table>
<thead>
<tr>
<th>Cache</th>
<th>Caches a function, but often accessed as arg in spades cache</th>
</tr>
</thead>
<tbody>
<tr>
<td>clearCache</td>
<td>Shows information about the objects in the cache</td>
</tr>
<tr>
<td>keepCache</td>
<td>Removes objects from the cache</td>
</tr>
<tr>
<td>clearStubArtifacts</td>
<td>Keeps only the objects described</td>
</tr>
<tr>
<td>clearplot</td>
<td>Removes any erroneous items in a cache repository</td>
</tr>
</tbody>
</table>

A module developer can build caching into their module by creating cached versions of their functions.

7 Plotting

Much of the underlying plotting functionality is provided by the quickPlot package.

There are several user-accessible plotting functions that are optimized for modularity and speed of plotting:

Commonly used:

| Plot          | The workhorse plotting function                                           |

Simulation diagrams:

<table>
<thead>
<tr>
<th>eventDiagram</th>
<th>Gantt chart representing the events in a completed simulation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>moduleDiagram</td>
<td>Network diagram of simplified module (object) dependencies.</td>
</tr>
<tr>
<td>objectDiagram</td>
<td>Sequence diagram of detailed object dependencies.</td>
</tr>
</tbody>
</table>

Other useful plotting functions:

<table>
<thead>
<tr>
<th>clearPlot</th>
<th>Helpful for resolving many errors</th>
</tr>
</thead>
<tbody>
<tr>
<td>clickValues</td>
<td>Extract values from a raster object at the mouse click location(s)</td>
</tr>
<tr>
<td>clickExtent</td>
<td>Zoom into a raster or polygon map that was plotted with Plot</td>
</tr>
<tr>
<td>clickCoordinates</td>
<td>Get the coordinates, in map units, under mouse click</td>
</tr>
<tr>
<td>dev</td>
<td>Specify which device to plot on, making a non-RStudio one as default</td>
</tr>
</tbody>
</table>
8 File operations

In addition to R’s file operations, we have added several here to aid in bulk loading and saving of files for simulation purposes:

- **loadFiles**: Load simulation objects according to a filelist
- **rasterToMemory**: Read a raster from file to RAM
- **saveFiles**: Save simulation objects according to outputs and params

9 Sample modules included in package

Several dummy modules are included for testing of functionality. These can be found with `file.path(find.package("SpaDES"), "samplemodules")`.

- **randomLandscapes**: Imports, updates, and plots several raster map layers
- **caribouMovement**: A simple agent-based (a.k.a., individual-based) model
- **fireSpread**: A simple model of a spatial spread process

10 Package options

SpaDES packages use the following **options** to configure behaviour:

- **spades.browserOnError**: If TRUE, the default, then any error rerun the same event with debugonce called on it to allow editing to be done. When that browser is continued (e.g., with ‘c’), then it will save it reparse it into the simList and rerun the edited version. This may allow a spades call to be recovered on error, though in many cases that may not be the correct behaviour. For example, if the simList gets updated inside that event in an iterative manner, then each run through the event will cause that iteration to occur. When this option is TRUE, then the event will be run at least 3 times: the first time makes the error, the second time has debugonce and the third time is after the error is addressed. TRUE is likely somewhat slower.
- **reproducible.cachePath**: The default local directory in which to cache simulation outputs. Default is a temporary directory (typically /tmp/RtmpXXX/SpaDES/cache).
- **spades.inputPath**: The default local directory in which to look for simulation inputs. Default is a temporary directory (typically /tmp/RtmpXXX/SpaDES/inputs).
- **spades.debug**: The default debugging value debug argument in spades(). Default is TRUE.
- **spades.lowMemory**: If true, some functions will use more memory efficient (but slower) algorithms. Default FALSE.
SpaDES.core-package

- `spades.moduleCodeChecks`: Should the various code checks be run during `simInit`. These are passed to `codetools::checkUsage`. Default is given by the function, plus these: list(suppressParamUnused = FALSE).
- `spades.modulePath`: The default local directory where modules and data will be downloaded and stored. Default is a temporary directory (typically `/tmp/RtmpXXX/SpaDES/modules`).
- `spades.moduleRepo`: The default GitHub repository to use when downloading modules via `downloadModule`. Default "PredictiveEcology/SpaDES-modules".
- `spades.nCompleted`: The maximum number of completed events to retain in the completed event queue. Default `1000L`.
- `spades.outputPath`: The default local directory in which to save simulation outputs. Default is a temporary directory (typically `/tmp/RtmpXXX/SpaDES/outputs`).
- `spades.switchPkgNamespaces`: Should the search path be modified to ensure a module’s required packages are listed first? Default `FALSE` to keep computational overhead down. If `TRUE`, there should be no name conflicts among package objects, but it is much slower, especially if the events are themselves fast.
- `spades.tolerance`: The default tolerance value used for floating point number comparisons. Default `.Machine$double.eps^0.5`

.addChangedAttr,.simList-method

Description
This will evaluate which elements in the simList object changed following this Cached function call. It will add a named character string as an attribute attr(x, ".Cache")$changed, indicating which ones changed. When this function is subsequently called again, only these changed objects will be returned. All other simList objects will remain unchanged.

Usage
## S4 method for signature 'simList'
.addChangedAttr(object, predigest, origArguments, ...)

Arguments
- **object**: Any R object returned from a function
- **predigest**: The full, element by element hash of the input arguments to that same function, e.g., from .robustDigest
- **origArguments**: These are the actual arguments (i.e., the values, not the names) that were the source for predigest
- **...**: Anything passed to methods.

See Also
- .addChangedAttr.
- .addChangedAttr

.addTagsToOutput,.simList-method

Description
See .addTagsToOutput.

Usage
## S4 method for signature 'simList'
.addTagsToOutput(object, outputObjects, FUN, preDigestByClass)
Arguments

- **object**: Any R object.
- **outputObjects**: Optional character vector indicating which objects to return. This is only relevant for list, environment (or similar) objects.
- **FUN**: A function.
- **preDigestByClass**: A list, usually from `.preDigestByClass`

Author(s)

Eliot McIntire

See Also

`.addTagsToOutput`

Description

See `.cacheMessage`.

Usage

```r
## S4 method for signature 'simList'
.cacheMessage(object, functionName, fromMemoise = getOption("reproducible.useMemoise", TRUE))
```

Arguments

- **object**: Any R object.
- **functionName**: A character string indicating the function name.
- **fromMemoise**: Logical. If TRUE, the message will be about recovery from memoised copy.

See Also

`.cacheMessage`
Description

See `.checkCacheRepo`.

Usage

```r
# S4 method for signature 'list'
.checkCacheRepo(object, create = FALSE)
```

Arguments

- **object** An R object
- **create** Logical. If TRUE, then it will create the path for cache.

See Also

`.checkCacheRepo`

---

`.fileExtensions` *File extensions map*

Description

How to load various types of files in R.

This function has two roles: 1) to proceed with the loading of files that are in a simList or 2) as a short cut to simInit(inputs = filelist). Generally not to be used by a user.

A data frame with information on how to load various types of files in R, containing the columns:

- **exts**: the file extension;
- **fun**: the function to use for files with this file extension;
- **package**: the package from which to load fun.

Because of the environment slot, this is not quite as straightforward as just saving the object. This also has option for file-backed Rasters.
.fileExtensions()

loadFiles(sim, filelist, ...)

## S4 method for signature 'simList,missing'
loadFiles(sim, filelist, ...)

## S4 method for signature 'missing,ANY'
loadFiles(sim, filelist, ...)

## S4 method for signature 'missing,missing'
loadFiles(sim, filelist, ...)

.saveFileExtensions()

saveSimList(sim, filename, keepFileBackedAsIs, envir = parent.frame())

Arguments

sim          simList object.
filelist     list or data.frame to call loadFiles directly from the filelist as described in Details
...          Additional arguments.
filename     Character string with the path for saving simList
keepFileBackedAsIs
             Logical. If there are file-backed Raster objects, should they be kept in their file-
             backed format, or loaded into RAM and saved within the .RData file. If TRUE
             (default), then the files will be copied to file.path(dirname(filename), "rasters").
envir        environment to search for objects to be saved.

Value

A saved .RData file in filename location.

inputs

Examples

## Not run:

# Load random maps included with package
.findSimList

Find simList in a nested list

Description
This is recursive, so it will find all simLists even if they are deeply nested.

Usage
.findSimList(x)

Arguments
x any object, used here only when it is a list with at least one simList in it
Description

See \texttt{.objSizeInclEnviros}.

Usage

\begin{verbatim}
## S4 method for signature 'simList'
.objSizeInclEnviros(object)
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{object} \hspace{1cm} Any R object.
\end{itemize}

See Also

\texttt{.objSizeInclEnviros}

---

Description

See \texttt{.parseElems}.

Usage

\begin{verbatim}
## S4 method for signature 'simList'
.parseElems(tmp, elems, envir)
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{tmp} \hspace{1cm} A evaluated object
  \item \texttt{elems} \hspace{1cm} A character string to be parsed
  \item \texttt{envir} \hspace{1cm} An environment
\end{itemize}

See Also

\texttt{.parseElems}
.preDigestByClass,simList-method

Pre-digesting method for simList

Description

Takes a snapshot of simList objects.

Usage

```r
## S4 method for signature 'simList'
.preDigestByClass(object)
```

Arguments

- `object` : Any R object.

Details

See `.preDigestByClass`.

Author(s)

Eliot McIntire

See Also

- `prepareOutput`

Description

A variable that can be used by module developers and model users to switch between a quick check of functions like `downloadData`, `Cache`. The module developer must actually use this in their code.

Usage

`.quickCheck`

Format

An object of class `logical` of length 1.

---

Description

This is intended to be used within the `Cache` function, but can be used to evaluate what a `simList` would look like once it is converted to a repeatably digestible object.

Usage

```r
## S4 method for signature 'simList'
robustDigest(object, .objects, length, algo, quick, classOptions)
```
Arguments

object      an object to digest.
.objects Character vector of objects to be digested. This is only applicable if there is a list, environment (or similar) named objects within it. Only this/these objects will be considered for caching, i.e., only use a subset of the list, environment or similar objects.

length Numeric. If the element passed to Cache is a Path class object (from e.g., asPath(filename)) or it is a Raster with file-backing, then this will be passed to digest::digest, essentially limiting the number of bytes to digest (for speed). This will only be used if quick = FALSE. Default is getOption("reproducible.length"), which is set to Inf.

algo The algorithms to be used; currently available choices are md5, which is also the default, sha1, crc32, sha512, xxhash32, xxhash64 and murmur32.

quick Logical. If TRUE, little or no disk-based information will be assessed, i.e., mostly its memory content. This is relevant for objects of class character, Path and Raster currently. For class character, it is ambiguous whether this represents a character string or a vector of file paths. The function will assess if it is a path to a file or directory first. If not, it will treat the object as a character string. If it is known that character strings should not be treated as paths, then quick = TRUE will be much faster, with no loss of information. If it is file or directory, then it will digest the file content, or basename(object). For class Path objects, the file's metadata (i.e., filename and file size) will be hashed instead of the file contents if quick = TRUE. If set to FALSE (default), the contents of the file(s) are hashed. If quick = TRUE, length is ignored. Raster objects are treated as paths, if they are file-backed.

classOptions Optional list. This will pass into .robustDigest for specific classes. Should be options that the .robustDigest knows what to do with.

Details

See robustDigest. This method strips out stuff from a simList class object that would make it otherwise not reproducibly digestible between sessions, operating systems, or machines. This will likely still not allow identical digest results across R versions.

robustDigest
**all.equal.simList**

---

.tagsByClass, simList-method
.tagsByClass for simList objects

**Description**

See .tagsByClass. Adds current moduleName, eventType, eventTime, and function:spades as userTags

**Usage**

```r
## S4 method for signature 'simList'
.tagsByClass(object)
```

**Arguments**

- `object` Any R object.

**Author(s)**

Eliot McIntire

**See Also**

.tagsByClass

---

**all.equal.simList** All equal method for simLists

---

**Description**

This function removes a few attributes that are added internally by SpaDES.core and are not relevant to the all.equal. One key element removed is any time stamps, as these are guaranteed to be different.

**Usage**

```r
## S3 method for class 'equal.simList'
all(target, current, ...)
```

**Arguments**

- `target` R object.
- `current` other R object, to be compared with `target`.
- `...` Further arguments for different methods, notably the following two, for numerical comparison:
append_attr

Value
See all.equal

Description
Ordinary base lists and vectors do not retain their attributes when subsetted or appended. This function appends items to a list while preserving the attributes of items in the list (but not of the list itself).

Usage
append_attr(x, y)

## S4 method for signature 'list, list'
append_attr(x, y)

Arguments
x, y A list of items with optional attributes.

Details
Similar to updateList but does not require named lists.

Value
An updated list with attributes.

Author(s)
Alex Chubaty and Eliot McIntire

Examples
library(igraph) # igraph exports magrittr's pipe operator
tmp1 <- list("apple", "banana") %>% lapply(. , `attributes<-' , list(type = "fruit"))
tmp2 <- list("carrot") %>% lapply(. , `attributes<-' , list(type = "vegetable"))
append_attr(tmp1, tmp2)
rm(tmp1, tmp2)
checkModuleLocal

Check for the existence of a remote module

Description

Looks in the remote repo for a module named name.

Usage

checkModuleLocal(name, path, version)

## S4 method for signature 'character,character'
checkModuleLocal(name, path, version)

## S4 method for signature 'character,ANY,ANY'
checkModuleLocal(name, path, version)

Arguments

name Character string giving the module name.
repo GitHub repository name. Default is "PredictiveEcology/SpaDES-modules", which is specified by the global option spades.moduleRepo.

Author(s)

Eliot McIntire and Alex Chubaty

checkModuleLocal

Check for the existence of a module locally

Description

Looks the module path for a module named name, and checks for existence of all essential module files listed below.

Usage

checkModuleLocal(name, path, version)

## S4 method for signature 'character,character,character'
checkModuleLocal(name, path, version)

## S4 method for signature 'character,ANY,ANY'
checkModuleLocal(name, path, version)
checkObject

Arguments

name Character string giving the module name.
path Local path to modules directory. Default is specified by the global option spades.modulePath.
version Character specifying the desired module version.

Details

- 'data/CHECKSUMS.txt'
- 'name.R'

Value

Logical indicating presence of the module (invisibly).

Author(s)

Alex Chubaty

checkObject Check for existence of object(s) referenced by a objects slot of a simList object

Description

Check that a named object exists in the provide simList environment slot, and optionally has desired attributes.

Usage

checkObject(sim, name, object, layer, ...)

## S4 method for signature 'simList,missing,Raster,character'
checkObject(sim, name, object,
    layer, ...)

## S4 method for signature 'simList,missing,ANY,missing'
checkObject(sim, name, object,
    layer, ...)

## S4 method for signature 'simList,character,missing,missing'
checkObject(sim, name,
    object, layer, ...)

## S4 method for signature 'simList,character,missing,character'
checkObject(sim, name,
    object, layer, ...)
## checkParams

Check use and existence of params passed to simulation.

### Description

Checks that all parameters passed are used in a module, and that all parameters used in a module are passed.

### Usage

```r
checkParams(sim, coreParams, ...)
```

### Arguments

- `sim`: A `simList` object.
- `coreParams`: List of default core parameters.
- `...`: Additional arguments. Not implemented.
Value

Invisibly return TRUE indicating object exists; FALSE if not. Sensible messages are be produced identifying missing parameters.

Author(s)

Alex Chubaty

---

**checksums**

*Calculate checksum for a module’s data files*

Description

Verify (and optionally write) checksums for data files in a module’s ‘data/’ subdirectory. The file ‘data/CHECKSUMS.txt’ contains the expected checksums for each data file. Checksums are computed using `reproducible::digest`, which is simply a wrapper around `digest::digest`.

Usage

```r
checksums(module, path, ...)
```

Arguments

- **module**
  Character string giving the name of the module.
- **path**
  Character string giving the path to the module directory.
- **...**
  Passed to `Checksums`, notably, `write`, `quickCheck`, `checksumFile` and `files`.

Details

Modules may require data that for various reasons cannot be distributed with the module source code. In these cases, the module developer should ensure that the module downloads and extracts the data required. It is useful to not only check that the data files exist locally but that their checksums match those expected.

Note

In version 1.2.0 and earlier, two checksums per file were required because of differences in the checksum hash values on Windows and Unix-like platforms. Recent versions use a different (faster) algorithm and only require one checksum value per file. To update your ‘CHECKSUMS.txt’ files using the new algorithm:

1. specify your module (`moduleName <- "my_module"`);
2. use a temp dir to ensure all modules get fresh copies of the data (`tmpdir <- file.path(tempdir(), "SpaDES_module")`);
3. download your module’s data to the temp dir (`downloadData(moduleName, tmpdir)`);
4. initialize a dummy simulation to ensure any 'data prep' steps in the .inputObjects section are run (`simInit(modules = moduleName)`);
5. recalculate your checksums and overwrite the file (checksums(moduleName, tmpdir, write = TRUE));
6. copy the new checksums file to your working module directory (the one not in the temp dir)
(file.copy(from = file.path(tmpdir, moduleName, 'data', 'CHECKSUMS.txt'),
    to = file.path(pathOtoOmyOmoduledir, moduleName, 'data', 'CHECKSUMS.txt'))

classFilter

Filter objects by class

Description
Based on http://stackoverflow.com/a/5158978/1380598.

Usage
classFilter(x, include, exclude, envir)

## S4 method for signature 'character,character,character,environment'
classFilter(x,
    include, exclude, envir)

## S4 method for signature 'character,character,character,missing'
classFilter(x, include,
    exclude)

## S4 method for signature 'character,character,missing,environment'
classFilter(x, include,
    envir)

## S4 method for signature 'character,character,missing,missing'
classFilter(x, include)

Arguments
x Character vector of object names to filter, possibly from ls.
include Class(es) to include, as a character vector.
exclude Optional class(es) to exclude, as a character vector.
envir The environment ins which to search for objects. Default is the calling environment.

Value
Vector of object names matching the class filter.

Note
inherits is used internally to check the object class, which can, in some cases, return results inconsistent with is. See http://stackoverflow.com/a/27923346/1380598. These (known) cases are checked manually and corrected.
Author(s)
Alex Chubaty

Examples

```r
## Not run:
## from global environment
a <- list(1:10)  # class 'list'
b <- letters  # class 'character'
d <- stats::runif(10)  # class 'numeric'
f <- sample(1L:10L) # class 'numeric', 'integer'
g <- lm(jitter(d) ~ d)  # class 'lm'
h <- glm(jitter(d) ~ d)  # class 'lm', 'glm'
classFilter(ls(), include = c("character", "list"))
classFilter(ls(), include = "numeric")
classFilter(ls(), include = "numeric", exclude = "integer")
classFilter(ls(), include = "lm")
classFilter(ls(), include = "lm", exclude = "glm")
rm(a, b, d, f, g, h)

## End(Not run)

## from local (e.g., function) environment
local({
e <- environment()
a <- list(1:10)  # class 'list'
b <- letters  # class 'character'
d <- stats::runif(10)  # class 'numeric'
f <- sample(1L:10L) # class 'numeric', 'integer'
g <- lm(jitter(d) ~ d)  # class 'lm'
h <- glm(jitter(d) ~ d)  # class 'lm', 'glm'
classFilter(ls(), include = c("character", "list"), envir = e)
classFilter(ls(), include = "numeric", envir = e)
classFilter(ls(), include = "numeric", exclude = "integer", envir = e)
classFilter(ls(), include = "lm", envir = e)
classFilter(ls(), include = "lm", exclude = "glm", envir = e)
rma, b, d, f, g, h)
})

## from another environment
e = new.env(parent = emptyenv())
ea$a <- list(1:10)  # class 'list'
ea$b <- letters  # class 'character'
ea$d <- stats::runif(10)  # class 'numeric'
ea$f <- sample(1L:10L) # class 'numeric', 'integer'
ea$g <- lm(jitter(e$d) ~ e$d)  # class 'lm'
ea$h <- glm(jitter(e$d) ~ e$d)  # class 'lm', 'glm'
classFilter(ls(e), include = c("character", "list"), envir = e)
classFilter(ls(e), include = "numeric", envir = e)
classFilter(ls(e), include = "numeric", exclude = "integer", envir = e)
classFilter(ls(e), include = "lm", envir = e)
classFilter(ls(e), include = "lm", exclude = "glm", envir = e)
```
Description

Because a simList works with an environment to hold all objects, all objects within that slot are pass-by-reference. That means it is not possible to simply copy an object with an assignment operator: the two objects will share the same objects. As one simList object changes so will the other. When this is not the desired behaviour, use this function. NOTE: use capital C, to limit confusion with data.table::copy(). See Copy.

Usage

```r
## S4 method for signature 'simList'
Copy(object, objects, queues)
```

Arguments

- `object`: An R object (likely containing environments) or an environment.
- `objects`: Whether the objects contained within the simList environment should be copied. Default TRUE, which may be slow.
- `queues`: Logical. Should the events queues (events, current, completed) be deep copied via data.table::copy

Author(s)

Eliot McIntire

Copy
copyModule

Create a copy of an existing module

Description

Create a copy of an existing module

Usage

```r
copyModule(from, to, path, ...)
```

```r
## S4 method for signature 'character,character,character'
copyModule(from, to, path, ...)
```

```r
## S4 method for signature 'character,character,missing'
copyModule(from, to, character,missing)
```

Arguments

- **from**: The name of the module to copy.
- **to**: The name of the copy.
- **path**: The path to a local module directory. Defaults to the path set by the `spades.modulepath` option. See `setPaths`.
- **...**: Additional arguments to `file.copy`, e.g., `overwrite = TRUE`.

Value

Invisible logical indicating success (TRUE) or failure (FALSE).

Author(s)

Alex Chubaty

Examples

```r
## Not run: copyModule(from, to)
```
createsOutput  
Define an output object of a module

Description

Used to specify an output object’s name, class, description and other specifications.

Usage

createsOutput(objectName, objectClass, desc, ...)

## S4 method for signature 'ANY,ANY,ANY'
createsOutput(objectName, objectClass, desc, ...)

## S4 method for signature 'character,character,character'
createsOutput(objectName, objectClass, desc, ...)

Arguments

- **objectName**: Character string to define the output object’s name.
- **objectClass**: Character string to specify the output object’s class.
- **desc**: Text string providing a brief description of the output object.
- **...**: Other specifications of the output object.

Value

A data frame suitable to be passed to outputObjects in a module’s metadata.

Author(s)

Yong Luo

Examples

```r
outputObjects <- dplyr::bind_rows(
  createsOutput(objectName = "outputObject1", objectClass = "character",
                desc = "this is for example"),
  createsOutput(objectName = "outputObject2", objectClass = "numeric",
                desc = "this is for example",
                otherInformation = "I am the second output object")
)
```
**defineModule**

*Define a new module.*

**Description**

Specify a new module’s metadata as well as object and package dependencies. Packages are loaded during this call. Any or all of these can be missing, with missing values set to defaults.

**Usage**

`defineModule(sim, x)`

```r
## S4 method for signature 'simList,list'
defineModule(sim, x)
```

**Arguments**

- `sim` A `simList` object from which to extract element(s) or in which to replace element(s).
- `x` A list with a number of named elements, referred to as the metadata. See details.

**Value**

Updated `simList` object.

**Required metadata elements**

- `name` Module name. Must match the filename (without the `.R` extension). This is currently not parsed by SpaDES; it is for human readers only.
- `description` Brief description of the module. This is currently not parsed by SpaDES; it is for human readers only.
- `keywords` Author-supplied keywords. This is currently not parsed by SpaDES; it is for human readers only.
- `childModules` If this contains any character vector, then it will be treated as a parent module. If this is a parent module, then this list entry will be read. For normal, i.e., 'child modules', this should be character(s).
- `authors` Module author information (as a vector of `person` objects). This is currently not parsed by SpaDES; it is for human readers only.
- `version` Module version number (will be coerced to `numeric_version` if a character or numeric are supplied). The `version` column is currently unimplemented. Once implemented, this should define what time frame this module is scientifically reasonable to be used for.
- `spatialExtent` The spatial extent of the module supplied via `raster::extent`. This is currently unimplemented. Once implemented, this should define what spatial region this module is scientifically reasonable to be used in.
- `timeunit` Time scale of the module (e.g., "day", "year"). This MUST be specified. It indicates what '1' unit of time means. For example, the developer can use `c(1,365)` to indicate that 1 unit of time is a day and 365 units of time are a year. This information is currently unimplemented. Once implemented, this should define what temporal extent of the module.
- `citation` List of character strings specifying module citation information. Alternatively, a list of filenames of `.bib` objects.
- `documentation` List of filenames referring to module documentation sources. This is currently not parsed by SpaDES; it is for human readers only.
- `reqdPkgss` List of R package names required by the module. These packages will be loaded when `simInit` is called. *R*
- `parameters` A `data.frame` specifying the parameters used in the module. Usually produced by `rbind-ing` the outputs of `defineParameter` calls. These parameters indicate the default values that will be used unless a module user overrides them with the `params` argument in the `simInit` function.
- `inputobjects` A `data.frame` specifying the data objects expected as inputs to the module, with columns `objectName` (class `characterHPI`), `objectclass` (class `characterHPI`), `objectpath` (class `characterHPI`), `objectname` (class `characterHPI`), `sourceurl` (class `characterHPI`), `sourceurl` (class `characterHPI`), `isnull` (class `logicalHPI`), `downloaddata` (class `logicalHPI`), `downloadmodule` (class `logicalHPI`), `isR` (class `logicalHPI`), and `isdata` (class `logicalHPI`). This data.frame identifies the objects that are expected, but does not do any loading of that object into the `simList`. The `sourceurl` column gives the developer the opportunity to identify the source of a data file that can be used with the model. This URL will be used if the user calls the `downloaddata` function, and they should indicate the range of values that are reasonable scientifically.
- `outputobjects` A `data.frame` specifying the data objects output by the module, with columns `objectName` (class `characterHPI`), `objectclass` (class `characterHPI`), `objectpath` (class `characterHPI`), `objectname` (class `characterHPI`), `sourceurl` (class `characterHPI`), `sourceurl` (class `characterHPI`), `isnull` (class `logicalHPI`), `downloaddata` (class `logicalHPI`), `downloadmodule` (class `logicalHPI`), `isR` (class `logicalHPI`), and `isdata` (class `logicalHPI`). If the raw data must be modified, the developer can use create a function called `inputobjects` and the module developer must write the necessary functions that will cause these objects to be put into the `simList`. This is currently unimplemented. Once implemented, this should define what spatial region this module is scientifically reasonable to be used in.

**Example**

```r
# Define a new module
defineModule()
```
defineModule

moduleDefaults

Examples

## Not run:
## a default version of the defineModule is created with a call to newModule
newModule("test", path = tempdir())

## view the resulting module file
if (interactive()) file.edit(file.path(tempdir(), "test", "test.R"))

# The default defineModule created by newModule is currently (SpaDES version 1.3.1.9044):
defineModule(sim, list(
  name = "test",
  description = "insert module description here",
  keywords = c("insert key words here"),
  authors = c(person(c("First", "Middle"), "Last",
                    email = "email@example.com", role = c("aut", "cre"))),
  childModules = character(0),
  version = list(SpaDES = "1.3.1.9044", test = "0.0.1"),
  spatialExtent = raster::extent(rep(NA_real_, 4)),
  timeframe = as.POSIXlt(c(NA, NA)),
  timeunit = NA_character_, # e.g., "year",
  citation = list("citation.bib"),
  documentation = list("README.txt", "test.Rmd"),
  reqdPkgs = list(),
  parameters = rbind(
    #defineParameter("paramName", "paramClass", value, min, max,
    # "parameter description"),
    defineParameter(".plotInitialTime", "numeric", NA, NA, NA,
      "This describes the simulation time at which the first plot event should occur"),
    defineParameter(".plotInterval", "numeric", NA, NA, NA,
      "This describes the simulation time at which the first plot event should occur"),
    defineParameter(".saveInitialTime", "numeric", NA, NA, NA,
      "This describes the simulation time at which the first save event should occur"),
    defineParameter(".saveInterval", "numeric", NA, NA, NA,
      "This describes the simulation time at which the first save event should occur")
  ),
  inputObjects = bind_rows(
    expectsInput(objectName = NA_character_, objectClass = NA_character_,
                 sourceURL = NA_character_, desc = NA_character_, other = NA_character_)
  ),
  outputObjects = bind_rows(
    createsOutput(objectName = NA_character_, objectClass = NA_character_,
                  desc = NA_character_, other = NA_character_)
  )
))
**defineParameter**  
*Define a parameter used in a module*

**Description**

Used to specify a parameter’s name, value, and set a default.

**Usage**

```r
defineParameter(name, class, default, min, max, desc)
```

```r
## S4 method for signature 'character,character,ANY,ANY,ANY,character'
defineParameter(name,  
    class, default, min, max, desc)
```

```r
## S4 method for signature 'character,character,ANY,missing,missing,character'
defineParameter(name,  
    class, default, desc)
```

```r
## S4 method for signature 'missing,missing,missing,missing,missing,missing'
defineParameter()
```

**Arguments**

- **name**: Character string giving the parameter name.
- **class**: Character string giving the parameter class.
- **default**: The default value to use when none is specified by the user. Non-standard evaluation is used for the expression.
- **min**: With **max**, used to define a suitable range of values. Non-standard evaluation is used for the expression.
- **max**: With **min**, used to define a suitable range of values. Non-standard evaluation is used for the expression.
- **desc**: Text string providing a brief description of the parameter.

**Value**

`data.frame`
Note

Be sure to use the correct NA type: logical (NA), integer (NA_integer_), real (NA_real_), complex (NA_complex_), or character (NA_character_). See NA.

P, params for accessing these parameters in a module.

Examples

```r
parameters <- rbind(
  defineParameter("lambda", "numeric", 1.23, desc = "intrinsic rate of increase"),
  defineParameter("P", "numeric", 0.2, 0, 1, "probability of attack")
)
```

```r
## Not run:
# Create a new module, then access parameters using \code{P}
tmpdir <- file.path(tempdir(), "test")
checkPath(tmpdir, create = TRUE)

# creates a new, "empty" module -- it has defaults for everything that is required
newModule("testModule", tmpdir)

# Look at new module code -- see defineParameter
createFile(file.path(tmpdir, "testModule", "testModule.R"))

# initialize the simList
mySim <- simInit(modules = "testModule",
  paths = list(modulePath = tmpdir))

# Access one of the parameters -- because this line is not inside a module
# function, we must specify the module name. If used within a module,
# we can omit the module name
P(mySim, "testModule")$useCache

## End(Not run)
```

depsEdgeList

Build edge list for module dependency graph

Description

Build edge list for module dependency graph
Usage

depsEdgeList(sim, plot)

## S4 method for signature 'simList,logical'
depsEdgeList(sim, plot)

## S4 method for signature 'simList,missing'
depsEdgeList(sim, plot)

Arguments

sim       A simList object.
plot      Logical indicating whether the edgelist (and subsequent graph) will be used for plotting. If TRUE, duplicated rows (i.e., multiple object dependencies between modules) are removed so that only a single arrow is drawn connecting the modules. Default is FALSE.

Value

A data.table whose first two columns give a list of edges and remaining columns the attributes of the dependency objects (object name, class, etc.).

Author(s)

Alex Chubaty

depsGraph  Build a module dependency graph

Description

Build a module dependency graph

Usage

depsGraph(sim, plot)

## S4 method for signature 'simList,logical'
depsGraph(sim, plot)

## S4 method for signature 'simList,missing'
depsGraph(sim)
doEvent.checkpoint

Arguments

sim        A simList object.
plot       Logical indicating whether the edgelist (and subsequent graph) will be used for
            plotting. If TRUE, duplicated rows (i.e., multiple object dependencies between
            modules) are removed so that only a single arrow is drawn connecting the mod-
            ules. Default is FALSE.

Value

An igraph object.

Author(s)

Alex Chubaty

Description

Save and reload the current state of the simulation, including the state of the random number gen-
erator, by scheduling checkpoint events.

Usage

doevent.checkpoint(sim, eventTime, eventType, debug = FALSE)

checkpointLoad(file)

.checkpointSave(sim, file)

checkpointFile(sim)

## S4 method for signature 'simList'
checkpointFile(sim)

checkpointFile(sim) <- value

## S4 replacement method for signature 'simList'
checkpointFile(sim) <- value

checkpointInterval(sim)

## S4 method for signature 'simList'
checkpointInterval(sim)
downloadData

```r
checkpointInterval(sim) <- value
```

## S4 replacement method for signature 'simList'

```r
checkpointInterval(sim) <- value
```

**Arguments**

- `sim` A `simList` simulation object.
- `eventTime` A numeric specifying the time of the next event.
- `eventType` A character string specifying the type of event: one of either "init", "load", or "save".
- `debug` Optional logical flag determines whether sim debug info will be printed (default `debug = FALSE`).
- `file` The checkpoint file.
- `value` The object to be stored at the slot.

**Details**

RNG save code adapted from: [http://www.cookbook-r.com/Numbers/Saving_the_state_of_the_random_number_generator/](http://www.cookbook-r.com/Numbers/Saving_the_state_of_the_random_number_generator/) and [https://stackoverflow.com/questions/13997444/](https://stackoverflow.com/questions/13997444/)

**Value**

Returns the modified `simList` object.

**Author(s)**

Alex Chubaty

Other functions to access elements of a `simList` object: `.addDepends, envir, events, globals, inputs, modules, objs, packages, params, paths, progressInterval, times`

---

**downloadData**

*Download module data*

**Description**

Download external data for a module if not already present in the module directory, or if there is a checksum mismatch indicating that the file is not the correct one.
downloadData

Usage

downloadData(module, path, quiet, quickCheck = FALSE,
    overwrite = FALSE, files = NULL, checked = NULL, urls = NULL,
    children = NULL, ...)

## S4 method for signature 'character,character,logical'
downloadData(module, path, quiet,
    quickCheck = FALSE, overwrite = FALSE, files = NULL,
    checked = NULL, urls = NULL, children = NULL, ...)

## S4 method for signature 'character,missing,missing'
downloadData(module, quickCheck,
    overwrite, files, checked, urls, children)

## S4 method for signature 'character,missing,logical'
downloadData(module, quiet,
    quickCheck, overwrite, files, checked, urls, children)

## S4 method for signature 'character,character,missing'
downloadData(module, path,
    quickCheck, overwrite, files, checked, urls, children)

Arguments

module  Character string giving the name of the module.

path    Character string giving the path to the module directory.

quiet   Logical. This is passed to download.file. Default is FALSE.

quickCheck Logical. If TRUE, then the check with local data will only use file.size instead of digest::digest. This is faster, but potentially much less robust.

overwrite Logical. Should local data files be overwritten in case they exist? Default is FALSE.

files    A character vector of length 1 or more if only a subset of files should be checked in the 'CHECKSUMS.txt' file.

checked  The result of a previous checksums call. This should only be used when there is no possibility that the file has changed, i.e., if downloadData is called from inside another function.

urls     Character vector of urls from which to get the data. This is automatically found from module metadata when this function invoked with SpaDES.core::downloadModule(..., data = TRUE).

See also prepInputs.

children The character vector of child modules (without path) to also run downloadData on

...     Passed to preProcess, e.g., purge
downloadModule

Details

downloadData requires a checksums file to work, as it will only download the files specified therein. Hence, module developers should make sure they have manually downloaded all the necessary data and ran checksums to build a checksums file.

There is an experimental attempt to use the googledrive package to download data from a shared (publicly or with individual users) file. To try this, put the Google Drive URL in sourceURL argument of expectsInputs in the module metadata, and put the filename once downloaded in the objectName argument. If using RStudio Server, you may need to use "out of band" authentication by setting options(httr.oob_default = TRUE). To avoid caching of Oauth credentials, set options(httr.oauth_cache = TRUE).

There is also an experimental option for the user to make a new ‘CHECKSUMS.txt’ file if there is a sourceURL but no entry for that file. This is experimental and should be used with caution.

Value

Invisibly, a list of downloaded files.

Author(s)

Alex Chubaty & Eliot McIntire

See Also

prepInputs, checksums, and downloadModule for downloading modules and building a checksums file.

Examples

```r
## Not run:
# For a Google Drive example
# In metadata:
expectsInputs("theFilename.zip", "NA", "NA",
  sourceURL = "https://drive.google.com/open?id=1Ngb-jIRC5s1G6zcuaaC8F1WdbkI_KBEx")
# create the checksums file
checksums("thisModule", "there", write = TRUE)
downloadData("thisModule", "there", files = "theFilename.zip")
## End(Not run)
```

---

downloadModule

Download a module from a SpaDES module GitHub repository

Description

Download a .zip file of the module and extract (unzip) it to a user-specified location.
**downloadModule**

**Usage**

```r
downloadModule(name, path, version, repo, data, quiet,
   quickCheck = FALSE, overwrite = FALSE)
```

```r
## S4 method for signature
## 'character,character,character,character,logical,logical,ANY,logical'
downloadModule(name,
   path, version, repo, data, quiet, quickCheck = FALSE,
   overwrite = FALSE)
```

```r
## S4 method for signature
## 'character,missing,missing,missing,missing,missing,ANY,ANY'
downloadModule(name,
   quickCheck, overwrite)
```

```r
## S4 method for signature 'character,ANY,ANY,ANY,ANY,ANY,ANY,ANY'
downloadModule(name,
   path, version, repo, data, quiet, quickCheck = FALSE,
   overwrite = FALSE)
```

**Arguments**

- **name**: Character string giving the module name.
- **path**: Character string giving the location in which to save the downloaded module.
- **version**: The module version to download. (If not specified, or NA, the most recent version will be retrieved.)
- **repo**: GitHub repository name, specified as "username/repo". Default is "PredictiveEcology/SpADES-modules", which is specified by the global option `spades.moduleRepo`. Only master branches can be used at this point.
- **data**: Logical. If TRUE, then the data that is identified in the module metadata will be downloaded, if possible. Default FALSE.
- **quiet**: Logical. This is passed to `download.file` (default FALSE).
- **quickCheck**: Logical. If TRUE, then the check with local data will only use `file.size` instead of `digest::digest`. This is faster, but potentially much less robust.
- **overwrite**: Logical. Should local module files be overwritten in case they exist? Default FALSE.

**Details**

Currently only works with GitHub repositories where modules are located in a `modules` directory in the root tree on the master branch. Module `.zip` files’ names should contain the version number and be inside their respective module folders (see `zipModule` for zip compression of modules).
Value

A list of length 2. The first element is a character vector containing a character vector of extracted files for the module. The second element is a tbl with details about the data that is relevant for the function, including whether it was downloaded or not, and whether it was renamed (because there was a local copy that had the wrong file name).

Note

downloadModule uses the GITHUB_PAT environment variable if a value is set. This alleviates 403 errors caused by too-frequent downloads. Generate a GitHub personal access token with no additional permissions at https://github.com/settings/tokens, and add this key to `.Renviron` as GITHUB_PAT='your-github-pat-here'.

The default is to overwrite any existing files in the case of a conflict.

zipModule for creating module .zip folders.

dyears

SpaDES time units

Description

SpaDES modules commonly use approximate durations that divide with no remainder among themselves. For example, models that simulate based on a "week" timestep, will likely want to fall in lock step with a second module that is a "year" timestep. Since, weeks, months, years don’t really have this behaviour because of: leap years, leap seconds, not quite 52 weeks in a year, months that are of different duration, etc. We have generated a set of units that work well together that are based on the astronomical or "Julian" year. In an astronomical year, leap years are added within each year with an extra 1/4 day, (i.e., 1 year == 365.25 days); months are defined as year/12, and weeks as year/52.

Usage

dyears(x)

## S4 method for signature 'numeric'
dyears(x)

dmonths(x)

## S4 method for signature 'numeric'
dmonths(x)
dweeks(x)

### S4 method for signature 'numeric'
dweeks(x)
dweek(x)
dmonth(x)
dyear(x)
dsecond(x)
dday(x)
dhour(x)
dNA(x)

### S4 method for signature 'ANY'
dNA(x)

**Arguments**

- **x**: numeric. Number of the desired units

**Details**

When these units are not correct, a module developer can create their own time unit using, and create a function to calculate the number of seconds in that unit using the "d" prefix (for duration), following the lubridate package standard: dfortnight <- function(x) lubridate::duration(dday(14)). Then the module developer can use "fortnight" as the module's time unit.

**Value**

Number of seconds within each unit

**Author(s)**

Eliot McIntire
Description

Accessor functions for the .xData slot, which is the default virtual slot for an S4 class object that inherits from an S3 object (specifically, the simList inherits from environment) in a simList object. These are included for advanced users.

Usage

```r
envir(sim)
```

```r
## S4 method for signature 'simList'
envir(sim)
```

envir(sim) <- value

```r
## S4 replacement method for signature 'simList'
envir(sim) <- value
```

Arguments

- `sim` A simList object from which to extract element(s) or in which to replace element(s).
- `value` The object to be stored at the slot.

Details

Currently, only get and set methods are defined. Subset methods are not.

Value

Returns or sets the value of the slot from the simList object.

Author(s)

Alex Chubaty

See Also

`SpaDES.core-package`, specifically the section 1.2.8 on simList environment.

Other functions to access elements of a simList object: `.addDepends, doEvent.checkpoint, events, globals, inputs, modules, objs, packages, params, paths, progressInterval, times`
Description
Create a Gantt Chart representing the events in a completed simulation. This event diagram is constructed using the completed event list. To change the number of events shown, provide an \( n \) argument.

Usage
```
eventDiagram(sim, n, startDate, ...)
```

## S4 method for signature 'simList,numeric,character'
```
eventDiagram(sim, n, startDate, ...)
```

## S4 method for signature 'simList,missing,character'
```
eventDiagram(sim, n, startDate, ...)
```

## S4 method for signature 'simList,missing,missing'
```
eventDiagram(sim, n, startDate, ...)
```

Arguments
- **sim** A `simList` object (typically corresponding to a completed simulation).
- **n** The number of most recently completed events to plot.
- **startDate** A character representation of date in `YYYY-MM-DD` format.
- **...** Additional arguments passed to `mermaid`. Useful for specifying height and width.

Details
Simulation time is presented on the x-axis, starting at date \('\text{startDate}'\). Each module appears in a color-coded row, within which each event for that module is displayed corresponding to the sequence of events for that module. Note that only the start time of the event is meaningful in these figures: the width of the bar associated with a particular module’s event DOES NOT correspond to an event’s “duration”.

Based on this StackOverflow answer: [http://stackoverflow.com/a/29999300/1380598](http://stackoverflow.com/a/29999300/1380598).

Value
Plots an event diagram as Gantt Chart, invisibly returning a `mermaid` object.

Note
A red vertical line corresponding to the current date may appear on the figure. This is useful for Gantt Charts generally but can be considered a ‘bug’ here.
Author(s)
Alex Chubaty

See Also
mermaid.

Description
Accessor functions for the events and completed slots of a simList object. These path functions will extract the values that were provided to the simInit function in the path argument.

Usage

```r
events(sim, unit)
```

## S4 method for signature 'simList,character'

```r
events(sim, unit)
```

## S4 method for signature 'simList,missing'

```r
events(sim) <- value
```

## S4 replacement method for signature 'simList'

```r
events(sim) <- value
```

```r
conditionalEvents(sim, unit)
```

## S4 method for signature 'simList,character'

```r
conditionalEvents(sim, unit)
```

## S4 method for signature 'simList,missing'

```r
conditionalEvents(sim, unit)
```

```r
current(sim, unit)
```

## S4 method for signature 'simList,character'

```r
current(sim, unit)
```

## S4 method for signature 'simList,missing'

```r
current(sim, unit)
```

```r
current(sim) <- value
```
## S4 replacement method for signature 'simList'

```r
current(sim) <- value
```

```r
completed(sim, unit, times = TRUE)
```

## S4 method for signature 'simList,character'

```r
completed(sim, unit, times = TRUE)
```

## S4 method for signature 'simList,missing'

```r
completed(sim) <- value
```

```
Arguments

<table>
<thead>
<tr>
<th>sim</th>
<th>A simList object from which to extract element(s) or in which to replace element(s).</th>
</tr>
</thead>
<tbody>
<tr>
<td>unit</td>
<td>Character. One of the time units used in SpaDES.</td>
</tr>
<tr>
<td>value</td>
<td>The object to be stored at the slot.</td>
</tr>
<tr>
<td>times</td>
<td>Logical. Should this function report the clockTime</td>
</tr>
</tbody>
</table>
```

## Details

By default, the event lists are shown when the simList object is printed, thus most users will not require direct use of these methods.

```
events       Scheduled simulation events (the event queue).
completed    Completed simulation events.
```

Currently, only get and set methods are defined. Subset methods are not.

## Value

Returns or sets the value of the slot from the simList object.

## Note

Each event is represented by a data.table row consisting of:

- **eventTime**: The time the event is to occur.
- **moduleName**: The module from which the event is taken.
- **eventType**: A character string for the programmer-defined event type.
expectsInput

Define an input object that the module expects.

Description
Used to specify an input object’s name, class, description, source url and other specifications.

Usage
expectsInput(objectName, objectClass, desc, sourceURL, ...)

## S4 method for signature 'ANY,ANY,ANY,ANY'
eventsInput(objectName, objectClass, desc, sourceURL, ...)

## S4 method for signature 'character,character,character,character'
eventsInput(objectName, objectClass, desc, sourceURL, ...)

## S4 method for signature 'character,character,character,missing'
eventsInput(objectName, objectClass, desc, sourceURL, ...)

Arguments

- **objectName**: Character string to define the input object’s name.
- **objectClass**: Character string to specify the input object’s class.
- **desc**: Text string providing a brief description of the input object.
- **sourceURL**: Character string to specify an URL to reach the input object, default is NA.
- **...**: Other specifications of the input object.

Value
A data.frame suitable to be passed to inputObjects in a module’s metadata.

Author(s)
Yong Luo
Examples

```r
inputObjects <- dplyr::bind_rows(
  expectsInput(objectName = "inputObject1", objectClass = "character",
              desc = "this is for example", sourceURL = "not available"),
  expectsInput(objectName = "inputObject2", objectClass = "numeric",
              desc = "this is for example", sourceURL = "not available",
              otherInformation = "I am the second input object")
)
```

Description

This is essentially a wrapper around the `spades` call that allows for multiple calls to `spades`. This function will use a single processor, or multiple processors if `beginCluster` has been run first or a cluster object is passed in the `cl` argument (gives more control to user).

Usage

```r
experiment(sim, replicates = 1, params, modules, objects = list(),
          inputs, dirPrefix = "simNum", substrLength = 3,
          saveExperiment = TRUE, experimentFile = "experiment.RData",
          clearSimEnv = FALSE, notOlderThan, cl, ...)
```

## S4 method for signature 'simList'

```r
experiment(sim, replicates = 1, params, modules,
          objects = list(), inputs, dirPrefix = "simNum", substrLength = 3,
          saveExperiment = TRUE, experimentFile = "experiment.RData",
          clearSimEnv = FALSE, notOlderThan, cl, ...)
```

Arguments

- `sim` A `simList` simulation object, generally produced by `simInit`.
- `replicates` The number of replicates to run of the same `simList`. See details and examples.
- `params` Like for `simInit`, but for each parameter, provide a list of alternative values. See details and examples.
- `modules` Like for `simInit`, but a list of module names (as strings). See details and examples.
- `objects` Like for `simInit`, but a list of named lists of named objects. See details and examples.
- `inputs` Like for `simInit`, but a list of inputs data.frames. See details and examples.
- `dirPrefix` String vector. This will be concatenated as a prefix on the directory names. See details and examples.
substrLength Numeric. While making outputPath for each spades call, this is the number of characters kept from each factor level. See details and examples.

saveExperiment Logical. Should params, modules, inputs, sim, and resulting experimental design be saved to a file. If TRUE are saved to a single list called experiment. Default TRUE.

experimentFile String. Filename if saveExperiment is TRUE; saved to outputPath(sim) in .RData format. See Details.

clearSimEnv Logical. If TRUE, then the envir(sim) of each simList in the return list is emptied. This is to reduce RAM load of large return object. Default FALSE.

notOlderThan Date or time. Passed to reproducible::Cache to update the cache. Default is NULL, meaning don’t update the cache. If Sys.time() is provided, then it will force a recache, i.e., remove old value and replace with new value. Ignored if cache is FALSE.

c1 A cluster object. Optional. This would generally be created using parallel::makeCluster or equivalent. This is an alternative way, instead of beginCluster(), to use parallelism for this function, allowing for more control over cluster use.

... Passed to spades. Specifically, debug, plotInitialTime, saveInitialTime, cache and/or notOlderThan. Caching is still experimental. It is tested to work under some conditions, but not all. See details.

Details

Generally, there are 2 reasons to do this: replication and varying simulation inputs to accomplish some sort of simulation experiment. This function deals with both of these cases. In the case of varying inputs, this function will attempt to create a fully factorial experiment among all levels of the variables passed into the function. If all combinations do not make sense, e.g., if parameters and modules are varied, and some of the parameters don’t exist in all combinations of modules, then the function will do an "all meaningful combinations" factorial experiment. Likewise, fully factorial combinations of parameters and inputs may not be the desired behaviour. The function requires a simList object, acting as the basis for the experiment, plus optional inputs and/or objects and/or params and/or modules and/or replications.

This function requires a complete simList: this simList will form the basis of the modifications as passed by params, modules, inputs, and objects. All params, modules, inputs or objects passed into this function will override the corresponding params, modules, inputs, or identically named objects that are in the sim argument.

This function is parallel aware, using the same mechanism as used in the raster package. Specifically, if you start a cluster using beginCluster, then this experiment function will automatically use that cluster. It is always a good idea to stop the cluster when finished, using endCluster.

Here are generic examples of how params, modules, objects, and inputs should be structured.

params = list(moduleName = list(paramName = list(val1, val2))).
modules = list(c("module1","module2"), c("module1","module3"))
objects = list(objName = list(object1=object1, object2=object2))
inputs = list( data.frame(file = pathToFile1, loadTime = 0, objectName = "landscape",) )
Output directories are changed using this function: this is one of the dominant side effects of this function. If there are only replications, then a set of subdirectories will be created, one for each replicate. If there are varying parameters and or modules, outputPath is updated to include a subdirectory for each level of the experiment. These are not nested, i.e., even if there are nested factors, all subdirectories due to the experimental setup will be at the same level. Replicates will be one level below this. The subdirectory names will include the module(s), parameter names, the parameter values, and input index number (i.e., which row of the inputs data.frame). The default rule for naming is a concatenation of:

1. The experiment level (arbitrarily starting at 1). This is padded with zeros if there are many experiment levels.
2. The module, parameter name and parameter experiment level (not the parameter value, as values could be complex), for each parameter that is varying.
3. The module set.
4. The input index number
5. Individual identifiers are separated by a dash.
6. Module - Parameter - Parameter index triplets are separated by underscore.

For example, the resulting directory name for changes to the spreadprob parameter in the firespread module and the N parameter in the caribouMovement module would be: 1_fir_spr_1-car_N_1 if substrLength is 3, the default.

Replication is treated slightly differently. outputPath is always 1 level below the experiment level for a replicate. If the call to experiment is not a factorial experiment (i.e., it is just replication), then the default is to put the replicate subdirectories at the top level of outputPath. To force this one level down, dirPrefix can be used or a manual change to outputPath before the call to experiment.

dirPrefix can be used to give custom names to directories for outputs. There is a special value, "simNum", that is used as default, which is an arbitrary number associated with the experiment. This corresponds to the row number in the attrHsimsL experimentB. This "simNum" can be used with other strings, such as dirPrefix = c("expt", "simNum").

The experiment structure is kept in two places: the return object has an attribute, and a file named experiment.RData (see argument experimentFile) located in outputPath.

substrLength, if 0, will eliminate the subdirectory naming convention and use only dirPrefix.

If cache = TRUE is passed, then this will pass this to spades, with the additional argument replicate = x, where x is the replicate number. That means that if a user runs experiment with replicate = 4 and cache = TRUE, then SpaDES will run 4 replicates, caching the results, including replicate = 1, replicate = 2, replicate = 3, and replicate = 4. Thus, if a second call to experiment with the exact same simList is passed, and replicates = 6, the first 4 will be taken from the cached copies, and replicate 5 and 6 will be run (and cached) as normal. If notOlderThan is used with a time that is more recent than the cached copy, then a new spades will be done, and the cached copy will be deleted from the cache repository, so there will only ever be one copy of a
particular replicate for a particular simList. NOTE: caching may not work as desired on a Windows machine because the sqlite database can only be written to one at a time, so there may be collisions.

**Value**

Invisibly returns a list of the resulting simList objects from the fully factorial experiment. This list has an attribute, which a list with 2 elements: the experimental design provided in a wide data.frame and the experiment values in a long data.frame. There is also a file saved with these two data.frames. It is named whatever is passed into experimentFile. Since returned list of simList objects may be large, the user is not obliged to return this object (as it is returned invisibly). Clearly, there may be objects saved during simulations. This would be determined as per a normal spades call, using outputs like, say, outputs(sims[[1]]).

simInit

**Examples**

```r
if (interactive()) {
  library(igraph) # use %>% in a few examples
  library(raster)

  tmpdir <- file.path(tempdir(), "examples")

  # Create a default simList object for use through these examples
  mySim <- simInit(
    times = list(start = 0.0, end = 2.0, timeunit = "year"),
    params = list(
      .globals = list(stackName = "landscape", burnStats = "nPixelsBurned"),
      # Turn off interactive plotting
      fireSpread = list(.plotInitialTime = NA),
      caribouMovement = list(.plotInitialTime = NA),
      randomLandscapes = list(.plotInitialTime = NA)
    ),
    modules = list("randomLandscapes", "fireSpread", "caribouMovement"),
    paths = list(modulePath = system.file("sampleModules", package = "SpADES.core"),
                 outputPath = tmpdir),
    # Save final state of landscape and caribou
    outputs = data.frame(objectName = c("landscape", "caribou"), stringsAsFactors = FALSE)
  )

  # Example 1 - test alternative parameter values
  # Create an experiment - here, 2 x 2 x 2 (2 levels of 2 params in fireSpread,
  # and 2 levels of 1 param in caribouMovement

  # Here is a list of alternative values for each parameter. They are length one
  # numerics here -- e.g., list(0.2, 0.23) for spreadprob in fireSpread module,
```
experiment

# but they can be anything, as long as it is a list.
experimentParams <- list(fireSpread = list(spreadprob = list(0.2, 0.23),
                                nfires = list(20, 10)),
                        caribouMovement = list(N = list(100, 1000)))
sims <- experiment(mySim, params = experimentParams)

# see experiment:
attr(sims, "experiment")

# Read in outputs from sims object
fireMaps <- do.call(stack, lapply(1:NROW(attr(sims, "experiment")$expDesign),
                                  function(x) sims[[x]]$landscape$fires))
if (interactive()) Plot(fireMaps, new = TRUE)

# Or reload objects from files, useful if sim objects too large to store in RAM
caribouMaps <- lapply(sims, function(sim) {
    caribou <- readRDS(outputs(sim)$file[outputs(sim)$ObjectName == "caribou"])
})
names(caribouMaps) <- paste0("caribou", 1:8)
# Plot whole named list
if (interactive()) Plot(caribouMaps, size = 0.1)

# Example 2 - test alternative modules
# Example of changing modules, i.e., caribou with and without fires
# Create an experiment - here, 2 x 2 x 2 (2 levels of 2 params in fireSpread,
# and 2 levels of 1 param in caribouMovement)
experimentModules <- list(
    c("randomLandscapes", "fireSpread", "caribouMovement"),
    c("randomLandscapes", "caribouMovement"))
sims <- experiment(mySim, modules = experimentModules)
attr(sims, "experiment")$expVals # shows 2 alternative experiment levels

# Example 3 - test alternative parameter values and modules
# Note, this isn't fully factorial because all parameters are not
# defined inside smaller module list
sims <- experiment(mySim, modules = experimentModules, params = experimentParams)
attr(sims, "experiment")$expVals # shows 10 alternative experiment levels

# Example 4 - manipulate manipulate directory names -
# "simNum" is special value for dirPrefix, it is converted to 1, 2, ...
sims <- experiment(mySim, params = experimentParams, dirPrefix = c("expt", "simNum"))
attr(sims, "experiment")$expVals # shows 8 alternative experiment levels, 24 unique
# parameter values

# Example 5 - doing replicate runs
sims <- experiment(mySim, replicates = 2)
attr(sims, "experiment")$expDesign # shows 2 replicates of same experiment

# Example 6 - doing replicate runs, but within a sub-directory
sims <- experiment(mySim, replicates = 2, dirPrefix = c("expt"))
lapply(sims, outputPath) # shows 2 replicates of same experiment, within a sub directory
# Example 7 - doing replicate runs, of a complex, non factorial experiment.
# Here we do replication, parameter variation, and module variation all together.
# This creates 20 combinations.
# The experiment function tries to make fully factorial, but won't
# if all the levels don't make sense. Here, changing parameter values 
# in the firespread module won't affect the simulation when the fireSpread
# module is not loaded:

# library(raster)
# beginCluster(20) # if you have multiple clusters available, use them here to save time
sims <- experiment(mySim, replicates = 2, params = experimentParams,
    modules = experimentModules,
    dirPrefix = c("expt", "simNum"))
# endCluster() # end the clusters
attr(sims, "experiment")

# Example 8 - Use replication to build a probability map.
# For this to be meaningful, we need to provide a fixed input landscape,
# not a randomLandscape for each experiment level. So requires 2 steps.
# Step 1 - run randomLandscapes module twice to get 2 randomly 
# generated landscape maps. We will use 1 right away, and we will 
# use the two further below
mySimRL <- simInit(
    times = list(start = 0.0, end = 0.1, timeunit = "year"),
    params = list(
        .globals = list(stackName = "landscape"),
        # Turn off interactive plotting
        randomLandscapes = list(.plotInitialTime = NA)
    ),
    modules = list("randomLandscapes"),
    paths = list(modulePath = system.file("sampleModules", package = "SpaDES.core"),
        outputPath = file.path(tmpdir, "landscapeMaps1")),
    outputs = data.frame(objectName = "landscape", saveTime = 0, stringsAsFactors = FALSE)
)
# Run it twice to get two copies of the randomly generated landscape
mySimRLOut <- experiment(mySimRL, replicate = 2)

# extract one of the random landscapes, which will be passed into next as an object
landscape <- mySimRLOut[[1]]$landscape

# here we don't run the randomLandscapes module; instead we pass in a landscape 
# as an object, i.e., a fixed input
mySimNoRL <- simInit(
    times = list(start = 0.0, end = 1, timeunit = "year"), # only 1 year to save time
    params = list(
        .globals = list(stackName = "landscape", burnStats = "nPixelsBurned"),
        # Turn off interactive plotting
        fireSpread = list(.plotInitialTime = NA),
        caribouMovement = list(.plotInitialTime = NA)
    ),
    modules = list("fireSpread", "caribouMovement"), # No randomLandscapes modules
    paths = list(modulePath = system.file("sampleModules", package = "SpaDES.core"),
        outputPath = tmpdir),
)
objects = c("landscape"), # Pass in the object here
# Save final state (the default if saveTime is not specified) of landscape and caribou
outputs = data.frame(objectName = c("landscape", "caribou"), stringsAsFactors = FALSE)
}

# Put outputs into a specific folder to keep them easy to find
outputPath(mySimNoRL) <- file.path(tmpdir, "example8")
sims <- experiment(mySimNoRL, replicates = 8) # Run experiment
attr(sims, "experiment") # shows the experiment, which in this case is just replicates

# list all files that were saved called 'landscape'
landscapeFiles <- dir(outputPath(mySimNoRL), recursive = TRUE, pattern = "landscape",
  full.names = TRUE)

# Can read in fires layers from disk since they were saved, or from the sims
# object
# fires <- lapply(sims, function(x) x$landscape$fires) #> stack
fires <- lapply(landscapeFiles, function(x) readRDS(x)$fires) #> stack()
fires[fires > 0] <- 1 # convert to 1s and 0s
fireProb <- sum(fires) / nlayers(fires) # sum them and convert to probability
if (interactive()) Plot(fireProb, new = TRUE)

# Example 9 - Pass in inputs, i.e., input data objects taken from disk
# Here, we, again, don't provide randomLandscapes module, so we need to
# provide an input stack called landscape. We point to the 2 that we have
# saved to disk in Example 8
mySimInputs <- simInit(
times = list(start = 0.0, end = 2.0, timeunit = "year"),
  params = list(
    .globals = list(stackName = "landscape", burnStats = "nPixelsBurned"),
    # Turn off interactive plotting
    fireSpread = list(.plotInitialTime = NA),
    caribouMovement = list(.plotInitialTime = NA)
  ),
  modules = list("fireSpread", "caribouMovement"),
  paths = list(modulePath = system.file("sampleModules", package = "SpaDES.core"),
               outputPath = tmpdir),
  # Save final state of landscape and caribou
  outputs = data.frame(objectName = c("landscape", "caribou"), stringsAsFactors = FALSE)
)
landscapeFiles <- dir(tmpdir, pattern = "landscape_year0", recursive = TRUE, full.names = TRUE)

# Varying inputs files - This could be combined with params, modules, replicates also
outputPath(mySimInputs) <- file.path(tmpdir, "example9")
sims <- experiment(mySimInputs,
  inputs = lapply(landscapeFiles, function(filenames) {
    data.frame(file = filenames, loadTime = 0,
               objectName = "landscape",
               stringsAsFactors = FALSE)
  }))

# load in experimental design object
experiment <- load(file = file.path(tmpdir, "example9", "experiment.RData")) %>% get()
print(experiment) # shows input files and details

# Example 10 - Use a very simple output dir name using substrLength = 0,
# i.e., just the simNum is used for outputPath of each spades call
outputPath(mySim) <- file.path(tmpdir, "example10")
sims <- experiment(mySim, modules = experimentModules, replicates = 2,
                   substrLength = 0)
lapply(sims, outputPath) # shows that the path is just the simNum

experiment <- load(file = file.path(tmpdir, "example10", "experiment.RData")) %>% get()
print(experiment) # shows input files and details

# Example 11 - use clearSimEnv = TRUE to remove objects from simList
# This will shrink size of return object, which may be useful because the
# return from experiment function may be a large object (it is a list of
# simLists). To see size of a simList, you have to look at the objects
# contained in the envir(simList). These can be obtained via objs(sim)
sapply(sims, function(x) object.size(objs(x))) %>% sum + object.size(sims)
# around 3 MB
# rerun with clearSimEnv = TRUE
sims <- experiment(mySim, modules = experimentModules, replicates = 2,
                   substrLength = 0, clearSimEnv = TRUE)
sapply(sims, function(x) object.size(objs(x))) %>% sum + object.size(sims)
# around 250 kB, i.e., all the simList contents except the objects.

# Example 12 - pass in objects
experimentObj <- list(landscape = lapply(landscapeFiles, readRDS) %>%
                        setNames(paste0("landscape", 1:2)))

# Pass in this list of landscape objects
sims <- experiment(mySimNoRL, objects = experimentObj)

# Remove all temp files
unlink(tmpdir, recursive = TRUE)
}

extractURL <- extractURL(objectName, sim, module)

## S4 method for signature 'character,missing'
extractURL(objectName, sim, module)

## S4 method for signature 'character,simList'
extractURL(objectName, sim, module)

### extractURL

**Extract a url from module metadata**

**Description**

This will get the sourceURL for the object named.

**Usage**

extractURL(objectName, sim, module)

## S4 method for signature 'character,missing'
extractURL(objectName, sim, module)

## S4 method for signature 'character,simList'
extractURL(objectName, sim, module)
Arguments

objectName  A character string of the object name in the metadata.
sim  A simList object from which to extract the sourceURL.
module  An optional character string of the module name whose metadata is to be used. If omitted, the function will use the currentModule(sim), if defined.

Value

The url.

Author(s)

Eliot McIntire

```r
fileName  Extract filename (without extension) of a file
```

Description

Extract filename (without extension) of a file

Usage

fileName(x)

Arguments

x  List or character vector

Value

A character vector.

Author(s)

Eliot McIntire
**getModuleVersion**  
*Find the latest module version from a SpaDES module repository*

---

**Description**

**Usage**

```r
getModuleVersion(name, repo)
```

```r
## S4 method for signature 'character,character'
getModuleVersion(name, repo)
```

```r
## S4 method for signature 'character,missing'
getModuleVersion(name)
```

**Arguments**

- `name`  
  Character string giving the module name.

- `repo`  
  GitHub repository name, specified as "username/repo". Default is "PredictiveEcology/SpaDES-modules", which is specified by the global option `spades.moduleRepo`. Only master branches can be used at this point.

**Details**

`getModuleVersion` extracts a module's most recent version by looking at the module `.zip` files contained in the module directory. It takes the most recent version, based on the name of the zip file.

See the modules vignette for details of module directory structure ([http://spades-core.predictiveecology.org/articles/ii-modules.html#module-directory-structure-modulename](http://spades-core.predictiveecology.org/articles/ii-modules.html#module-directory-structure-modulename)), and see our SpaDES-modules repo for details of module repository structure ([https://github.com/PredictiveEcology/SpaDES-modules](https://github.com/PredictiveEcology/SpaDES-modules)).

**Author(s)**

Alex Chubaty

**See Also**

`zipModule` for creating module `.zip` folders.
globals

Get and set simulation globals.

Description

globals, and the alias G, accesses or sets the "globals" in the simList. This currently is not an explicit slot in the simList, but it is a .globals element in the params slot of the simList.

Usage

globals(sim)

## S4 method for signature 'simList'
globals(sim)

globals(sim) <- value

## S4 replacement method for signature 'simList'
globals(sim) <- value

G(sim)

## S4 method for signature 'simList'
G(sim)

G(sim) <- value

## S4 replacement method for signature 'simList'
G(sim) <- value

Arguments

sim A simList object from which to extract element(s) or in which to replace element(s).

value The object to be stored at the slot.

See Also

SpaDES.core-package, specifically the section 1.2.1 on Simulation Parameters.

Other functions to access elements of a simList object: .addDepends, doEvent.checkpoint, envir, events, inputs, modules, objs, packages, params, paths, progressInterval, times
**initialize, simList-method**

*Generate a simList object*

**Description**

Given the name or the definition of a class, plus optionally data to be included in the object, `new` returns an object from that class.

**Usage**

```r
## S4 method for signature 'simList'
initialize(.Object, ...)
```

```r
## S4 method for signature 'simList_'
initialize(.Object, ...)
```

**Arguments**

- `.Object` A simList object.
- `...` Optional Values passed to any or all slot

---

**inputObjects**

*Metadata accessors*

**Description**

These accessors extract the metadata for a module (if specified) or all modules in a simList if not specified.

**Usage**

```r
inputObjects(sim, module)
```

```r
## S4 method for signature 'simList'
inputObjects(sim, module)
```

```r
## S4 method for signature 'simList_'
outputObjects(sim, module)
```

```r
## S4 method for signature 'simList'
outputObjects(sim, module)
```

```r
## S4 method for signature 'simList_'
reqdPkgs(sim, module)
```
## S4 method for signature 'simList'
reqPkg(sim, module)
documentation(sim, module)

## S4 method for signature 'simList'
documentation(sim, module)
citation(package, lib.loc = NULL, auto = NULL, module = character())

## S4 method for signature 'simList'
citation(package, lib.loc = NULL, auto = NULL, module = character())

## S4 method for signature 'character'
citation(package, lib.loc = NULL, auto = NULL, module = character())

### Arguments

- **sim**: A `simList` object from which to extract element(s) or in which to replace element(s).
- **module**: Optional character string indicating which module params should come from.
- **package**: For compatibility with `citation`. This can be a `simList` or a character string for a package name.
- **lib.loc**: a character vector with path names of R libraries, or the directory containing the source for package, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
- **auto**: a logical indicating whether the default citation auto-generated from the package 'DESCRIPTION' metadata should be used or not, or NULL (default), indicating that a 'CITATION' file is used if it exists, or an object of class "packageDescription" with package metadata (see below).

### Description

These functions are one of three mechanisms to add the information about which input files to load in a spades call and the information about which output files to save. 1) As arguments to a `simInit` call. Specifically, `inputs` or `outputs`. See ?simInit. 2) With the `inputs(simList)` or `outputs(simList)` function call. 3) By adding a function called `inputObjects` inside a module, which will be executed during the `simInit` call. This last way is the most "modular" way to create default data sets for your model. See below for more details.
Usage

```r
inputs(sim)

## S4 method for signature 'simList'
inputs(sim)
inputs(sim) <- value

## S4 replacement method for signature 'simList'
inputs(sim) <- value

outputs(sim)

## S4 method for signature 'simList'
outputs(sim)
outputs(sim) <- value

## S4 replacement method for signature 'simList'
outputs(sim) <- value

inputArgs(sim)

## S4 method for signature 'simList'
inputArgs(sim)
inputArgs(sim) <- value

## S4 replacement method for signature 'simList'
inputArgs(sim) <- value

outputArgs(sim)

## S4 method for signature 'simList'
outputArgs(sim)
outputArgs(sim) <- value

## S4 replacement method for signature 'simList'
outputArgs(sim) <- value
```

Arguments

- **sim**: A `simList` object from which to extract element(s) or in which to replace element(s).
- **value**: The object to be stored at the slot. See Details.
Details

Accessor functions for the inputs and outputs slots in a simList object.

Value

Returns or sets the value(s) of the input or output slots in the simList object.

inputs function or argument in simInit
inputs accepts a data.frame, with up to 7 columns. Columns are:

- **file** required, a character string indicating the file path. There is no default.
- **objectName** optional, character string indicating the name of the object that the loaded file will be assigned to in the simList object. Defaults to the filename without file extension or directory information.
- **fun** optional, a character string indicating the function to use to load that file. Defaults to the known extensions in Spades (found by examining .Nfileextensions). The package and fun can be jointly specified here as `packagename::functionname`, e.g., `braster::raster`.
- **package** optional character string indicating the package in which to find the fun);
- **loadTime** optional numeric, indicating when in simulation time the file should be loaded. The default is the highest priority at start, i.e., at the very start.
- **interval** optional numeric, indicating at what interval should this same exact file be reloaded from disk, e.g,. 10 would mean every 10 time units. The default is NA or no interval, i.e, load the file only once as described in loadtime arguments
- **arguments** is a list of lists of named arguments, one list for each fun. For example, if `fun = raster`, `arguments = list(native = TRUE)` will pass the argument "native = TRUE" to raster. If there is only one list, then it is assumed to apply to all files and will be recycled as per normal R rules of recycling for each fun.

Currently, only file is required. All others will be filled with defaults if not specified.

See the modules vignette for more details (browseVignettes("SpaDES.core")).

outputs function or argument in simInit
outputs accepts a data.frame similar to the inputs data.frame, but with up to 6 columns.

- **objectName** required, character string indicating the name of the object in the simList that will be saved to disk (without the simD prefix).
- **file** optional, a character string indicating the file path to save to. The default is to concatenate objectName with the model timeunit and savetime, separated by underscore, '_'. So a default filename would be `fires_yearQNrds. 
- **fun** optional, a character string indicating the function to use to save that file. The default is saveRDS
- **package** optional character string indicating the package in which to find the fun);
**inputs**

saveTime  optional numeric, indicating when in simulation time the file should be saved. The default is the lowest priority is a list of lists of named arguments, one list for each fun. For example, if `fun = "write.csv", arguments = `See the modules vignette for more details (browseVignettes("SpaDES.core")).

**Note**

The automatic file type handling only adds the correct extension from a given fun and package. It does not do the inverse, from a given extension find the correct fun and package.

**See Also**

`SpaDES.core-package`, specifically the section 1.2.2 on loading and saving.

Other functions to access elements of a simList object: .addDepends, doEvent.checkpoint, envir, events, globals, modules, objs, packages, params, paths, progressInterval, times

**Examples**

```r
# inputs
# Start with a basic empty simList
sim <- simInit()

test <- 1:10
library(igraph) # for %>%
library(reproducible) # for checkPath
tmpdir <- file.path(tempdir(), "inputs") # %>% checkPath(create = TRUE)
tmpFile <- file.path(tmpdir, "test.rds")
saveRDS(test, file = tmpFile)
inputs(sim) <- data.frame(file = tmpFile) # using only required column, "file"
inputs(sim) # see that it is not yet loaded, but when it is scheduled to be loaded
simOut <- spades(sim)
inputs(simOut) # confirm it was loaded
simOut$test

# can put data.frame for inputs directly inside simInit call
allTifs <- dir(system.file("maps", package = "quickPlot"),
               full.names = TRUE, pattern = "tif")

# next: .objectNames are taken from the filenames (without the extension)
# This will load all 5 tifs in the SpaDES sample directory, using
# the raster function in the raster package, all at time = 0
if (require("rgdal", quietly = TRUE)) {
  sim <- simInit(
    inputs = data.frame(
      files = allTifs,
      functions = "raster",
      package = "raster",
```
## inputs

```r
loadTime = 0,
stringsAsFactors = FALSE)
)

# A fully described inputs object, including arguments:
files <- dir(system.file("maps", package = "quickPlot"),
  full.names = TRUE, pattern = "tif")
# arguments must be a list of lists. This may require I() to keep it as a list
# once it gets coerced into the data.frame.
arguments = I(rep(list(native = TRUE), length(files)))
filelist = data.frame(
  objectName = paste0("Maps", 1:5),
  files = files,
  functions = "raster::raster",
  arguments = arguments,
  loadTime = 0,
  intervals = c(rep(NA, length(files) - 1), 10)
)
inputs(sim) <- filelist
spades(sim)
```

# Example showing loading multiple objects from global environment onto the
# same object in the simList, but at different load times
a1 <- 1
a2 <- 2
# Note arguments must be a list of NROW(inputs), with each element itself being a list,
# which is passed to do.call(fun[x], arguments[[x]]), where x is row number, one at a time
args <- lapply(1:2, function(x) {
  list(x = paste0("a", x),
       envir = environment()) # may be necessary to specify in which envir a1, a2
                              # are located, if not in an interactive session
})
inputs <- data.frame(objectName = "a", loadTime = 1:2, fun = "base::get", arguments = I(args))
a <- simInit(inputs = inputs, times = list(start = 0, end = 1))
a <- spades(a)
identical(a1, a$a)
end(a) <- 3
a <- spades(a) # different object (a2) loaded onto a$a
identical(a2, a$a)

# Clean up after
unlink(tmpdir, recursive = TRUE)

# outputs
```r
library(igraph) # for %>%
tmpdir <- file.path(tmpdir, "outputs") %>% checkPath(create = TRUE)
tmpFile <- file.path(tmpdir, "temp.rds")
```
tempObj <- 1:10

# Can add data.frame of outputs directly into simInit call
sim <- simInit(objects = c("tempObj"),
               outputs = data.frame(objectName = "tempObj"),
               paths = list(outputPath = tmpdir))
outputs(sim) # To see what will be saved, when, what filename
sim <- spades(sim)
outputs(sim) # To see that it was saved, when, what filename

# Also can add using assignment after a simList object has been made
sim <- simInit(objects = c("tempObj"), paths = list(outputPath = tmpdir))
outputs(sim) <- data.frame(objectName = "tempObj", saveTime = 1:10)
sim <- spades(sim)
outputs(sim) # To see that it was saved, when, what filename.

# can do highly variable saving
tempObj2 <- paste("val",1:10)
df1 <- data.frame(col1 = tempObj, col2 = tempObj2)
sim <- simInit(objects = c("tempObj", "tempObj2", "df1"),
               paths = list(outputPath = tmpdir))
outputs(sim) = data.frame(
    objectName = c(rep("tempObj", 2), rep("tempObj2", 3), "df1"),
    saveTime = c(c(1,4), c(2,6,7), end(sim)),
    fun = c(rep("saveRDS", 5), "write.csv"),
    package = c(rep("base", 5), "utils"),
    stringsAsFactors = FALSE)
# since write.csv has a default of adding a column, x, with rownames, must add additional
# argument for 6th row in data.frame (corresponding to the write.csv function)
outputArgs[[6]] <- list(row.names=FALSE)
sim <- spades(sim)
outputs(sim)

# read one back in just to test it all worked as planned
newObj <- read.csv(dir=tmpdir, pattern = "year10.csv", full.name = TRUE)
newObj

# using saving with SpaDES-aware methods
# To see current ones SpaDES can do
.saveFileExtensions()

library(raster)
if (require(rgdal)) {
  ras <- raster(ncol = 4, nrow = 5)
  ras[] <- 1:20

  sim <- simInit(objects = c("ras"), paths = list(outputPath = tmpdir))
  outputs(sim) = data.frame(
     file = "test",
     fun = "writeRaster",
     package = "raster",
     objectName = "ras",
     stringsAsFactors = FALSE)
inSeconds

Convert time units

Description
In addition to using the lubridate package, some additional functions to work with times are provided.
This function takes a numeric with a "unit" attribute and converts it to another numeric with a different time attribute. If the units passed to argument units are the same as attr(time, "unit"), then it simply returns input time.

Usage

inSeconds(unit, envir, skipChecks = FALSE)
convertTimeunit(time, unit, envir, skipChecks = FALSE)

Arguments

unit Character. One of the time units used in SpaDES or user defined time unit, given as the unit name only. See details.
envir An environment. This is where to look up the function definition for the time unit. See details.
skipChecks For speed, the internal checks for classes and missingness can be skipped. Default FALSE.
time Numeric. With a unit attribute, indicating the time unit of the input numeric. See Details.
Format

An object of class character of length 12.

Details

Current pre-defined units are found within the `spadesTimes()` function. The user can define a new unit. The unit name can be anything, but the function definition must be of the form "dunitName", e.g., `dyear` or `dfortnight`. The unit name is the part without the d and the function name definition includes the d. This new function, e.g., `dfortnight <- function(x) lubridate::duration(dday(14))` can be placed anywhere in the search path or in a module.

Because of R scoping, if `envir` is a `simList` environment, then this function will search there first, then up the current `search()` path. Thus, it will find a user defined or module defined unit before a SpaDES unit. This means that a user can override the `dyear` given in SpaDES, for example, which is 365.25 days, with `dyear <- function(x) lubridate::duration(dday(365))`.

If time has no unit attribute, then it is assumed to be seconds.

Value

A numeric vector of length 1, with unit attribute set to "seconds".

Alex Chubaty & Eliot McIntire
Eliot McIntire

loadPackages

Load packages.

Description

Load and optionally install additional packages.

Usage

`loadPackages(packageList, install = FALSE, quiet = TRUE)`

```r
## S4 method for signature 'character'
loadPackages(packageList, install = FALSE, quiet = TRUE)

## S4 method for signature 'list'
loadPackages(packageList, install = FALSE, quiet = TRUE)

## S4 method for signature '"NULL"'
loadPackages(packageList, install = FALSE, quiet = TRUE)
```
Arguments

`packageList`  A list of character strings specifying the names of packages to be loaded.

`install`  Logical flag. If required packages are not already installed, should they be installed?

`quiet`  Logical flag. Should the final "packages loaded" message be suppressed?

Value

Specified packages are loaded and attached using `require()`, invisibly returning a logical vector of successes.

Author(s)

Alex Chubaty

See Also

`require`.

Examples

```r
## Not run:
pkgs <- list("raster", "lme4")
loadPackages(pkgs) # loads packages if installed
loadPackages(pkgs, install = TRUE) # loads packages after installation (if needed)

## End(Not run)
```

Description

Because of the environment slot, `simList` objects don't correctly memoise a `simList`. This method for `simList` converts the object to a `simList_` first.

Usage

```r
## S3 method for class 'simList'
makeMemoisable(x)

## S3 method for class 'simList_'
unmakeMemoisable(x)
```
**maxTimeunit**

Arguments

- `x`  
  An object to make memoisable. See individual methods in other packages.

Value

A `simList` object or a `simList`, in the case of `unmakeMemoisable`.

See Also

`makeMemoisable`

---

### maxTimeunit

**Determine the largest timestep unit in a simulation**

**Description**

Determine the largest timestep unit in a simulation

**Usage**

```r
maxTimeunit(sim)
```

```r
## S4 method for signature 'simList'
maxTimeunit(sim)
```

**Arguments**

- `sim`  
  A `simList` simulation object.

**Value**

The timeunit as a character string. This defaults to `NA` if none of the modules has explicit units.

**Author(s)**

Eliot McIntire and Alex Chubaty
minTimeunit  

*Determine the smallest timeunit in a simulation*

**Description**

When modules have different timeunit, SpaDES automatically takes the smallest (e.g., "second") as the unit for a simulation.

**Usage**

```r
minTimeunit(sim)
```

## S4 method for signature 'simList'

```r
minTimeunit(sim)
```

## S4 method for signature 'list'

```r
minTimeunit(sim)
```

**Arguments**

- `sim`  
  A simList simulation object.

**Value**

The timeunit as a character string. This defaults to "second" if none of the modules has explicit units.

**Author(s)**

Eliot McIntire

---

moduleCoverage 

*Calculate module coverage of unit tests*

**Description**

Calculate the test coverage by unit tests for the module and its functions.

**Usage**

```r
moduleCoverage(name, path)
```

## S4 method for signature 'character,character'

```r
moduleCoverage(name, path)
```

## S4 method for signature 'character,missing'

```r
moduleCoverage(name)
```
moduleCoverage

Arguments

name  Character string. The module’s name.
path  Character string. The path to the module directory (default is the current working directory).

Value

Return a list of two coverage objects and two data.table objects. The two coverage objects are named ‘moduleCoverage’ and ‘functionCoverage’. The ‘moduleCoverage’ object contains the percent value of unit test coverage for the module. The ‘functionCoverage’ object contains percentage values for unit test coverage for each function defined in the module. Please use report to view the coverage information. Two data.tables give the information of all the tested and untested functions in the module.

Note

When running this function, the test files must be strictly placed in the ‘tests/testthat/’ directory under module path. To automatically generate this folder, please set unitTests = TRUE when creating a new module using newModule. To accurately test your module, the test filename must follow the format test-functionName.R.

## End(Not run)
moduleDefaults

**Description**
Where individual elements are missing in `defineModule`, these defaults will be used.

**Usage**

```r
moduleDefaults
```

**Format**
An object of class `list` of length 12.

moduleDiagram

**Description**
Create a network diagram illustrating the simplified module dependencies of a simulation. Offers a less detailed view of specific objects than does plotting the `depsEdgeList` directly with `objectDiagram`.

**Usage**

```r
moduleDiagram(sim, type, showParents, ...)
```

```r
def moduleDiagram(sim, type, showParents, 
...)
def moduleDiagram(sim, type, showParents, 
...)
```

**Arguments**

- `sim` A `simList` object (typically corresponding to a completed simulation).
- `type` Character string, either "rgl" for `igraph::rglplot` or "tk" for `igraph::tkplot`. Default missing, which uses regular plot.
- `showParents` Logical. If TRUE, then any children that are grouped into parent modules will be grouped together by colored blobs. Internally, this is calling `moduleGraph`. Default FALSE.
- `...` Additional arguments passed to plotting function specified by `type`. 
moduleGraph

Value
Plots module dependency diagram.

Author(s)
Alex Chubaty

See Also
igraph, moduleGraph for a version that accounts for parent and children module structure.

moduleGraph  Build a module dependency graph

Description
This is still experimental, but this will show the hierarchical structure of parent and children modules and return a list with an igraph object and an igraph communities object, showing the groups. Currently only tested with relatively simple structures.

Usage
moduleGraph(sim, plot, ...)

## S4 method for signature 'simList,logical'
moduleGraph(sim, plot, ...)

## S4 method for signature 'simList,missing'
moduleGraph(sim, plot, ...)

Arguments

sim  A simList object.
plot Logical indicating whether the edgelist (and subsequent graph) will be used for plotting. If TRUE, duplicated rows (i.e., multiple object dependencies between modules) are removed so that only a single arrow is drawn connecting the modules. Default is FALSE.
... Arguments passed to Plot

Value
A list with 2 elements, an igraph object and an igraph communities object.

moduleDiagram

moduleMetadata  Parse and extract module metadata

Description

Parse and extract module metadata

Usage

moduleMetadata(sim, module, path)

## S4 method for signature 'missing,character,character'
moduleMetadata(module, path)

## S4 method for signature 'missing,character,missing'
moduleMetadata(module)

## S4 method for signature 'ANY,ANY,ANY'
moduleMetadata(sim, module, path)

Arguments

<table>
<thead>
<tr>
<th>sim</th>
<th>A simList simulation object, generally produced by simInit.</th>
</tr>
</thead>
<tbody>
<tr>
<td>module</td>
<td>Character string. Your module’s name.</td>
</tr>
<tr>
<td>path</td>
<td>Character string specifying the file path to modules directory. Default is to use the spades.modulePath option.</td>
</tr>
</tbody>
</table>

Value

A list of module metadata, matching the structure in defineModule.

Author(s)

Alex Chubaty

defineModule
Examples

```r
path <- system.file("sampleModules", package = "SpaDES.core")
sampleModules <- dir(path)
# turn off code checking -- don't need it here
opts <- options("spades.moduleCodeChecks" = FALSE,
                 "spades.useRequire" = FALSE)

x <- moduleMetadata(sampleModules[3], path = path)

# using simList
mySim <- simInit(
  times = list(start = 2000.0, end = 2001.0, timeunit = "year"),
  params = list(.
    .globals = list(stackName = "landscape")
  ),
  modules = list("caribouMovement"),
  paths = list(modulePath = system.file("sampleModules", package = "SpaDES.core"))
)
moduleMetadata(sim = mySim)

# turn code checking back on -- don't need it here
options(opts)
```

Description

Accessor functions for the `depends` and `modules` slots in a `simList` object. These are included for advanced users.

- `depends` List of simulation module dependencies. (advanced)
- `modules` List of simulation modules to be loaded. (advanced)
- `inputs` List of loaded objects used in simulation. (advanced)

Usage

```r
modules(sim, hidden = FALSE)
```

## S4 method for signature 'simList'
```r
modules(sim, hidden = FALSE)
```

```r
modules(sim) <- value
```

## S4 replacement method for signature 'simList'
```r
modules(sim) <- value
```
depends(sim)

## S4 method for signature 'simList'
depends(sim)

depends(sim) <- value

## S4 replacement method for signature 'simList'
depends(sim) <- value

### Arguments

**sim**
A `simList` object from which to extract element(s) or in which to replace element(s).

**hidden**
Logical. If TRUE, show the default core modules.

**value**
The object to be stored at the slot.

### Details
Currently, only get and set methods are defined. Subset methods are not.

### Value
Returns or sets the value of the slot from the `simList` object.

### Author(s)
Alex Chubaty

### See Also
`SpaDES.core-package`, specifically the section 1.2.7 on Modules and dependencies.
Other functions to access elements of a `simList` object: `.addDepends`, `doEvent.checkpoint`, `envir`, `events`, `globals`, `inputs`, `objs`, `packages`, `params`, `paths`, `progressInterval`, `times`
moduleVersion

Usage

moduleVersion(module, path, sim, envir = NULL)

## S4 method for signature 'character,character,missing'
moduleVersion(module, path, envir)

## S4 method for signature 'character,missing,missing'
moduleVersion(module, envir)

## S4 method for signature 'character,missing,simList'
moduleVersion(module, sim, envir)

Arguments

module  Character string. Your module’s name.
path  Character string specifying the file path to modules directory. Default is to use
       the spades.modulePath option.
sim  A simList simulation object, generally produced by simInit.
envir  Optional environment in which to store parsed code. This may be useful if the
        same file is being parsed multiple times. This function will check in that envir
        for the parsed file before parsing again. If the envir is transient, then this will
        have no effect.

Value
	numeric_version indicating the module’s version.

Author(s)

Alex Chubaty

See Also

moduleMetadata

Examples

path <- system.file("sampleModules", package = "SpaDES.core")

# using filepath
moduleVersion("caribouMovement", path)

# using simList
mySim <- simInit(
  times = list(start = 2000.0, end = 2002.0, timeunit = "year"),
  params = list(
    .globals = list(stackName = "landscape", burnStats = "nPixelsBurned")
  ),
  modules = list("caribouMovement"),
newModule

Create new module from template

Description

Autogenerate a skeleton for a new SpaDES module, a template for a documentation file, a citation file, a license file, a 'README.txt' file, and a folder that contains unit tests information. The `newModuleDocumentation` will not generate the module file, but will create the other files.

Usage

```
newModule(name, path, ...)  # S4 method for signature 'character,character'
newModule(name, path, ...)  # S4 method for signature 'character,missing'
```

Arguments

- `name`: Character string specifying the name of the new module.
- `path`: Character string. Subdirectory in which to place the new module code file. The default is the current working directory.
- `...`: Additional arguments. Currently, only the following are supported:
  - `open`: Logical. Should the new module file be opened after creation? Default TRUE.
  - `unitTests`: Logical. Should the new module include unit test files? Default TRUE. Unit testing relies on the `testthat` package.
  - `type`: Character string specifying one of "child" (default), or "parent".
  - `children`: Required when `type = "parent"`. A character vector specifying the names of child modules.
**Details**

All files will be created within a subdirectory named `name` within the path:

- `path/`
  - `name/` # contains additional module R scripts
  - `R/` # directory for all included data
  - `data/` # contains checksums for data files
  - `tests/` # contains unit tests for module code
  - `citation.bib` # bibtex citation for the module
  - `LICENSE.txt` # describes module’s legal usage
  - `README.txt` # provide overview of key aspects
  - `name.R` # module code file (incl. metadata)
  - `name.Rmd` # documentation, usage info, etc.

**Value**

Nothing is returned. The new module file is created at `path/name.R`, as well as ancillary files for documentation, citation, ‘LICENSE’, ‘README’, and ‘tests’ directory.

**Note**

On Windows there is currently a bug in RStudio that prevents the editor from opening when `file.edit` is called. Similarly, in RStudio on macOS, there is an issue opening files where they are opened in an overlayed window rather than a new tab. `file.edit` does work if the user types it at the command prompt. A message with the correct lines to copy and paste is provided.

newModule("myModule", "modules")

## create a new parent module in the "modules" subdirectory.
newModule("myParentModule", "modules", type = "parent", children = c("child1", "child2"))

## End(Not run)
```
newModuleCode  Create new module code file

Description
Create new module code file

Usage
newModuleCode(name, path, open, type, children)

### S4 method for signature 'character,character,logical,character,character'
newModuleCode(name, path, open, type, children)

Arguments
- **name**: Character string specifying the name of the new module.
- **path**: Character string. Subdirectory in which to place the new module code file. The default is the current working directory.
- **open**: Logical. Should the new module file be opened after creation? Default TRUE.
- **type**: Character string specifying one of "child" (default), or "parent".
- **children**: Required when type = "parent". A character vector specifying the names of child modules.

newProgressBar Progress bar

Description

Shows a progress bar that is scaled to simulation end time.

Usage

newProgressBar(sim)

setProgressBar(sim)

Arguments

sim A simList simulation object.

Details

The progress bar object is stored in a separate environment, #’ .pkgEnv.

Author(s)

Alex Chubaty and Eliot McIntire
objectDiagram

Simulation object dependency diagram

Description
Create a sequence diagram illustrating the data object dependencies of a simulation. Offers a more detailed view of specific objects than does plotting the depsEdgeList directly with moduleDiagram.

Usage
objectDiagram(sim, ...)

## S4 method for signature 'simList'
objectDiagram(sim, ...)

Arguments
- **sim**: A simList object (typically corresponding to a completed simulation).
- **...**: Additional arguments passed to mermaid. Useful for specifying height and width.

Value
Plots a sequence diagram, invisibly returning a mermaid object.

Author(s)
Alex Chubaty

See Also
mermaid.

objectSynonyms
Identify synonyms in a simList

Description
This will create active bindings amongst the synonyms. To minimize copying, the first one that exists in the character vector will become the "canonical" object. All others named in the character vector will be activeBindings to that canonical one. This synonym list will be assigned to the envir, as an object named objectSynonyms. That object will have an attribute called, bindings indicating which one is the canonical one and which is/are the activeBindings. EXPERIMENTAL: If the objects are removed during a spades call by, say, a module, then at the end of the event, the spades call will replace the bindings. In other words, if a module deletes the object, it will "come back". This may not always be desired.
objectSynonyms

Usage

objectSynonyms(envir, synonyms)

Arguments

envir
An environment, which in the context of SpaDES.core is usually a simList to find and/or place the objectSynonyms object.
synonyms
A list of synonym character vectors, such as list(c("age", "ageMap", "age2"), c("veg", "vegMap", "veg2"))

Details

This is very experimental and only has minimal tests. Please report if this is not working, and under what circumstances (e.g., please submit a reproducible example to our issues tracker)
This function will append any new objectSynonym to any pre-existing objectSynonym in the envir. Similarly, this function assumes transitivity, i.e., if age and ageMap are synonyms, and ageMap and timeSinceFire are synonyms, then age and timeSinceFire must be synonyms.

Value

Active bindings in the envir so that all synonyms point to the same canonical object, e.g., they would be at envir[[synonym[[1]][1]]] and envir[[synonym[[1]][2]]], if a list of length one is passed into synonyms, with a character vector of length two. See examples.

Examples

sim <- simInit()
sim$age <- 1:10;
sim <- objectSynonyms(sim, list(c("age", "ageMap")))

identical(sim$ageMap, sim$age)
sim$age <- 4
identical(sim$ageMap, sim$age)
sim$ageMap <- 2:5
sim$ageMap[3] <- 11
identical(sim$ageMap, sim$age)

# Also works to pass it in as an object
objectSynonyms <- list(c("age", "ageMap"))
sim <- simInit(objects = list(objectSynonyms = objectSynonyms))
identical(sim$ageMap, sim$age) # they are NULL at this point
sim$age <- 1:10
identical(sim$ageMap, sim$age) # they are not NULL at this point

## More complicated, with 'updating' i.e., you can add new synonyms to previous
sim <- simInit()
os <- list(c("age", "ageMap"), c("vegMap", "veg"), c("studyArea", "studyArea2"))
os2 <- list(c("ageMap", "timeSinceFire", "tsf"),
        c("systime", "systime2"),
        c("vegMap", "veg"))
Extract or replace an object from the simulation environment

Description

The `[[` and `$` operators provide "shortcuts" for accessing objects in the simulation environment. I.e., instead of using `envir(sim)$object` or `envir(sim)["object"]`, one can simply use `sim$object` or `sim[["object"]].`

Usage

```r
objs(sim, ...)  
```

```
## S4 method for signature 'simList'
objs(sim, ...)
  
objs(sim) <- value
```

Arguments

- `sim` A `simList` object from which to extract element(s) or in which to replace element(s).
- `...` passed to `ls`
- `value` objects to assign to the `simList`

Details

`objs` can take `...` arguments passed to `ls`, allowing, e.g. `all.names=TRUE` `objs<-` requires takes a named list of values to be assigned in the simulation environment.

Value

Returns or sets a list of objects in the `simList` environment.
See Also

*SpaDES.core-package*, specifically the section 1.2.1 on Simulation Parameters.

Other functions to access elements of a simList object: `.addDepends, doEvent.checkpoint, envir, events, globals, inputs, modules, packages, params, paths, progressInterval, times`

---

`objSize.simList`  
*Object size for simList*

---

**Description**

Recursively, runs `object.size` on the simList environment. Currently, this will not assess `object.size` of the other elements.

**Usage**

```r
## S3 method for class 'simList'
objSize(x, quick = getOption("reproducible.quick", FALSE))
```

**Arguments**

- `x`  
  An object

- `quick`  
  Logical. Only some methods use this. E.g., Path class objects. In which case, `file.size` will be used instead of `object.size`.

**Examples**

```r
a <- simInit(objects = list(d = 1:10, b = 2:20))
objSize(a)
object.size(a)
```

---

`openModules`  
*Open all modules nested within a base directory*

---

**Description**

This is just a convenience wrapper for opening several modules at once, recursively. A module is defined as any file that ends in `.R` or `.r` and has a directory name identical to its filename. Thus, this must be case sensitive.
openModules

Usage

openModules(name, path)

## S4 method for signature 'character,character'
openModules(name, path)

## S4 method for signature 'missing,missing'
openModules()

## S4 method for signature 'missing,character'
openModules(path)

## S4 method for signature 'character,missing'
openModules(name)

## S4 method for signature 'simList,missing'
openModules(name)

Arguments

name      Character vector with names of modules to open. If missing, then all modules will be opened within the basedir.

path     Character string of length 1. The base directory within which there are only module subdirectories.

Value

Nothing is returned. All file are open via `file.edit`.

Note

On Windows there is currently a bug in RStudio that prevents the editor from opening when `file.edit` is called. `file.edit` does work if the user types it at the command prompt. A message with the correct lines to copy and paste is provided.

Author(s)

Eliot McIntire

Examples

## Not run: openModules("~\SpaDESModules")
packages

Get module or simulation package dependencies

Description

Get module or simulation package dependencies

Usage

packages(sim, modules, paths, filenames, envir, clean = FALSE, ...)

## S4 method for signature 'ANY'

packages(sim, modules, paths, filenames, envir, 
clean = FALSE, ...)

Arguments

sim A simList object.
modules Character vector, specifying the name or vector of names of module(s)
paths Character vector, specifying the name or vector of names of paths(s) for those modules. If path not specified, it will be taken from getOption("spades.modulePath"), which is set with setPaths
filenames Character vector specifying filenames of modules (i.e. combined path & module). If this is specified, then modules and path are ignored.
envir Optional environment in which to store parsed code. This may be useful if the same file is being parsed multiple times. This function will check in that envir for the parsed file before parsing again. If the envir is transient, then this will have no effect.
clean Optional logical. If TRUE, it will scrub any references to github repositories, e.g., "PredictiveEcology/reproducible" will be returned as "reproducible"
...

Value

A sorted character vector of package names.

Author(s)

Alex Chubaty & Eliot McIntire

See Also

Other functions to access elements of a simList object: .addDepends, doEvent.checkpoint, envir, events, globals, inputs, modules, objs, params, paths, progressInterval, times
paddedFloatToChar

Convert numeric to character with padding

Description

Convert numeric to character with padding

Usage

paddedFloatToChar(x, padL = ceiling(log10(x + 1)), padR = 3, pad = "0")

Arguments

x numeric. Number to be converted to character with padding
padL numeric. Desired number of digits on left side of decimal. If not enough, pad will be used to pad.
padR numeric. Desired number of digits on right side of decimal. If not enough, pad will be used to pad.
pad character to use as padding (nchar(pad) == 1 must be TRUE). Passed to stri_pad

Value

Character string representing the filename.

Author(s)

Eliot McIntire and Alex Chubaty

Examples

paddedFloatToChar(1.25)
paddedFloatToChar(1.25, padL = 3, padR = 5)

params

Get and set simulation parameters.

Description

params and P access the parameter slot in the simList. params has a replace method, so can be used to update a parameter value.
Usage

params(sim)

## S4 method for signature 'simList'
params(sim)

params(sim) <- value

## S4 replacement method for signature 'simList'
params(sim) <- value

P(sim, module, param)

parameters(sim, asDF = FALSE)

## S4 method for signature 'simList'
parameters(sim, asDF = FALSE)

Arguments

- **sim**: A simList object from which to extract element(s) or in which to replace element(s).
- **value**: The object to be stored at the slot.
- **module**: Optional character string indicating which module params should come from.
- **param**: Optional character string indicating which parameter to choose.
- **asDF**: Logical. For parameters, if TRUE, this will produce a single data.frame of all model parameters. If FALSE, then it will return a data.frame with 1 row for each parameter within nested lists, with the same structure as params.

Value

Returns or sets the value of the slot from the simList object.

Note

The differences between P, params and being explicit with passing arguments are mostly a question of speed and code compactness. The computationally fastest way to get a parameter is to specify moduleName and parameter name, as in: P(sim, "moduleName", "paramName") (replacing moduleName and paramName with your specific module and parameter names), but it is more verbose than P(sim)$paramName. Note: the important part for speed (e.g., 2-4x faster) is specifying the moduleName. Specifying the parameter name is <5

See Also

SpaDES.core-package, specifically the section 1.2.1 on Simulation parameters.
Other functions to access elements of a simList object: .addDepends, doEvent.checkpoint, envir.events.globals, inputs, modules, objs, packages, paths, progressInterval, times
**paths**  

Examples

```r
modules <- list("randomLandscapes")
paths <- list(modulePath = system.file("sampleModules", package = "SpaDES.core"))
mySim <- simInit(modules = modules, paths = paths,
                 params = list(globals = list(stackName = "landscape")))
parameters(mySim)
```

---

 Specify paths for modules, inputs, and outputs

---

**Description**

Accessor functions for the `paths` slot in a `simList` object.

dataPath will return `file.path(modulePath(sim), currentModule(sim), "data")`. dataPath, like currentModule, is namespaced. This means that when it is used inside a module, then it will return _that model-specific_ information. For instance, if used inside a module called "movingAgent", then `currentModule(sim)` will return "movingAgent", and `dataPath(sim)` will return `file.path(modulePath(sim), "model", "data")`.

**Usage**

```r
paths(sim)
```

```r
## S4 method for signature 'simList'
paths(sim)
```

```r
paths(sim) <- value
```

```r
## S4 replacement method for signature 'simList'
paths(sim) <- value
```

```r
cachePath(sim)
```

```r
## S4 method for signature 'simList'
cachePath(sim)
```

```r
cachePath(sim) <- value
```

```r
## S4 replacement method for signature 'simList'
cachePath(sim) <- value
```

```r
inputPath(sim)
```

```r
## S4 method for signature 'simList'
inputPath(sim)
```

```r
inputPath(sim) <- value
```
paths

```
## S4 replacement method for signature 'simList'
inputPath(sim) <- value
outputPath(sim)

## S4 method for signature 'simList'
outputPath(sim) <- value

## S4 replacement method for signature 'simList'
outputPath(sim) <- value

## S4 replacement method for signature 'simList'
modulePath(sim, module)

## S4 method for signature 'simList'
modulePath(sim, module)
modulePath(sim) <- value

## S4 replacement method for signature 'simList'
modulePath(sim) <- value

dataPath(sim)

## S4 method for signature 'simList'
dataPath(sim)
```

**Arguments**

- `sim` A `simList` object from which to extract element(s) or in which to replace element(s).
- `value` The object to be stored at the slot.
- `module` The optional character string of the module(s) whose paths are desired. If omitted, will return all `modulePath`s, if more than one exist.

**Details**

These are ways to add or access the file paths used by spades. There are four file paths: `cachePath`, `modulePath`, `inputPath`, and `outputPath`. Each has a function to get or set the value in a `simList` object. If no paths are specified, the defaults are as follows:

- `cachePath`: `getOption("reproducible.cachePath")`;
- `inputPath`: `getOption("spades.modulePath")`;
- `modulePath`: `getOption("spades.inputPath")`;
- `inputPath`: `getOption("spades.outputPath")`.  

Plot,simList-method

Value

Returns or sets the value of the slot from the simList object.

See Also

SpaDES.core-package, specifically the section 1.2.4 on Simulation Paths.

Other functions to access elements of a simList object: addDepends, doEvent.checkpoint, envir.events.globals, inputs, modules, objs, packages, params, progressInterval, times

---

Plot,simList-method  Plot method for simList objects

Description

Extends Plot for simList objects.

Usage

```r
## S4 method for signature 'simList'
Plot(..., new = FALSE, addTo = NULL, gp = gpar(),
       gptext = gpar(), gpAxis = gpar(), axes = FALSE, speedup = 1,
       size = 5, cols = NULL, col = NULL, zoomExtent = NULL,
       visualSqueeze = NULL, legend = TRUE, legendRange = NULL,
       legendText = NULL, pch = 19, title = NULL,
       na.color = "#FFFFFF00", zero.color = NULL, length = NULL,
       arr = NULL, plotFn = "plot")
```

Arguments

- `...`:
  A combination of spatialObjects or non-spatial objects. For many object classes, there are specific Plot methods. Where there are no specific ones, the base plotting will be used internally. This means that for objects with no specific Plot methods, many arguments, such as addTo, will not work. See details.

- `new`:
  Logical. If TRUE, then the previous named plot area is wiped and a new one made; if FALSE, then the ... plots will be added to the current device, adding or rearranging the plot layout as necessary. Default is FALSE. This currently works best if there is only one object being plotted in a given Plot call. However, it is possible to pass a list of logicals to this, matching the length of the ... objects. Use clearPlot to clear the whole plotting device.

- `addTo`:
  Character vector, with same length as .... This is for overplotting, when the overplot is not to occur on the plot with the same name, such as plotting a SpatialPoints* object on a RasterLayer.

- `gp`:
  A gpar object, created by `gpar` function, to change plotting parameters (see `grid` package).

- `gptext`:
  A gpar object for the title text. Default gpar(col = "black").
gpAxis
A gpar object for the axes. Default gpar(col = "black").

axes
Logical or "L", representing the left and bottom axes, over all plots.

speedup
Numeric. The factor by which the number of pixels is divided by to plot rasters. See Details.

size
Numeric. The size, in points, for SpatialPoints symbols, if using a scalable symbol.

cols
(also col) Character vector or list of character vectors of colours. See details.

col
(also cols) Alternative to cols to be consistent with plot. cols takes precedence, if both are provided.

zoomExtent
An Extent object. Supplying a single extent that is smaller than the rasters will call a crop statement before plotting. Defaults to NULL. This occurs after any downsampling of rasters, so it may produce very pixelated maps.

visualSqueeze
Numeric. The proportion of the white space to be used for plots. Default is 0.75.

legend
Logical indicating whether a legend should be drawn. Default is TRUE.

legendRange
Numeric vector giving values that, representing the lower and upper bounds of a legend (i.e., 1:10 or c(1,10) will give same result) that will override the data bounds contained within the grobToPlot.

legendText
Character vector of legend value labels. Defaults to NULL, which results in a pretty numeric representation. If Raster* has a Raster Attribute Table (rat; see raster package), this will be used by default. Currently, only a single vector is accepted. The length of this must match the length of the legend, so this is mostly useful for discrete-valued rasters.

pch
see ?par.

title
Logical or character string. If logical, it indicates whether to print the object name as the title above the plot. If a character string, it will print this above the plot. NOTE: the object name is used with addTo, not the title. Default NULL, which means print the object name as title, if no other already exists on the plot, in which case, keep the previous title.

na.color
Character string indicating the color for NA values. Default transparent.

zero.color
Character string indicating the color for zero values, when zero is the minimum value, otherwise, zero is treated as any other color. Default transparent.

length
Numeric. Optional length, in inches, of the arrow head.

arr
A vector of length 2 indicating a desired arrangement of plot areas indicating number of rows, number of columns. Default NULL, meaning let Plot function do it automatically.

plotFn
An optional function name to do the plotting internally, e.g., "barplot" to get a barplot() call. Default "plot".

Details
Plot for simList class objects

See Plot. This method strips out stuff from a simList class object that would make it otherwise not reproducibly digestible between sessions, operating systems, or machines. This will likely still not allow identical digest results across R versions.
Use Pattern Oriented Modeling to fit unknown parameters

Description

This is very much in alpha condition. It has been tested on simple problems, as shown in the examples, with up to 2 parameters. It appears that DEoptim is the superior package for the stochastic problems. This should be used with caution as with all optimization routines. This function can nevertheless take optim or genoud as optimizers, using stats::optim or rgenoud::genoud, respectively. However, these latter approaches do not seem appropriate for stochastic problems, and have not been widely tested and are not supported within POM.

Usage

POM(sim, params, objects = NULL, objFn, cl, optimizer = "DEoptim", sterr = FALSE, ..., objFnCompare = "MAD", optimControl = NULL, NaNRetries = NA, logObjFnVals = FALSE, weights, useLog = FALSE)

## S4 method for signature 'simList,character'
POM(sim, params, objects = NULL, objFn, cl, optimizer = "DEoptim", sterr = FALSE, ..., objFnCompare = "MAD", optimControl = NULL, NaNRetries = NA, logObjFnVals = FALSE, weights, useLog = FALSE)

Arguments

sim
A simList simulation object, generally produced by simInit.

params
Character vector of parameter names that can be changed by the optimizer. These must be accessible with params(sim) internally.

objects
A optional named list (must be specified if objFn is not). The names of each list element must correspond to an object in the .GlobalEnv and the list elements must be objects or functions of objects that can be accessed in the ls(sim) internally. These will be used to create the objective function passed to the optimizer. See details and examples.

objFn
An optional objective function to be passed into optimizer. If missing, then POM will use objFnCompare and objects instead. If using POM with a SpaDES simulation, this objFn must contain a spades call internally, followed by a derivation of a value that can be minimized but the optimizer. It must have, as first argument, the values for the parameters. See example.

c1
A cluster object. Optional. This would generally be created using parallel::makeCluster or equivalent. This is an alternative way, instead of beginCluster(), to use parallelism for this function, allowing for more control over cluster use.
optimizer

The function to use to optimize. Default is "DEoptim". Currently it can also be "optim" or "rgenoud", which use stats::optim or rgenoud::genoud, respectively. The latter two do not seem optimal for stochastic problems and have not been widely tested.

sterr

Logical. If using optimizer = "optim", the hessian can be calculated. If this is TRUE, then the standard errors can be estimated using that hessian, assuming normality.

... All objects needed in objFn

objFnCompare

Character string. Either, "MAD" or "RMSE" indicating that inside the objective function, data and prediction will be compared by Mean Absolute Deviation or Root Mean Squared Error. Default is "MAD".

optimControl

List of control arguments passed into the control of each optimization routine. Currently, only passed to DEoptim.control when optimizer is "DEoptim"

NaNRetries

Numeric. If greater than 1, then the function will retry the objective function for a total of that number of times if it results in an NaN. In general this should not be used as the objective function should be made so that it doesn’t produce NaN. But, sometimes it is difficult to diagnose stochastic results.

logObjFnVals

Logical or Character string indicating a filename to log the outputs. Ignored if objFn is supplied. If TRUE (and there is no objFn supplied), then the value of the individual patterns will be output the console if being run interactively or to a tab delimited text file named ObjectiveFnValues.txt (or that passed by the user here) at each evaluation of the POM created objective function. See details.

weights

Numeric. If provided, this vector will be multiplied by the standardized deviations (possibly MAD or RMSE) as described in objects. This has the effect of weighing each standardized deviation (pattern–data pair) to a user specified amount in the objective function.

useLog

Logical. Should the data patterns and output patterns be logged (log) before calculating the objFnCompare. i.e., mean(abs(log(output) - log(data))). This should be length 1 or length objects. It will be recycled if length >1, less than objects.

Details

There are two ways to use this function, via 1) objFn or 2) objects.

1. The user can pass the entire objective function to the objFn argument that will be passed directly to the optimizer. For this, the user will likely need to pass named objects as part of the ....

2. The slightly simpler approach is to pass a list of actual data–simulated data’ pairs as a named list in objects and specify how these objects should be compared via objFnCompare (whose default is Mean Absolute Deviation or "MAD").

Option 1 offers more control to the user, but may require more knowledge. Option 1 should likely contain a call to simInit(Copy(simList)) and spades internally. See examples that show simple examples of each type, option 1 and option 2. In both cases, params is required to indicate which parameters can be varied in order to achieve the fit.
Currently, option 1 only exists when optimizer is "DEoptim", the default.

The upper and lower limits for parameter values are taken from the metadata in the module. Thus, if the module metadata does not define the upper and lower limits, or these are very wide, then the optimization may have troubles. Currently, there is no way to override these upper and lower limits; the module metadata should be changed if there needs to be different parameter limits for optimization.

`objects` is a named list of data–pattern pairs. Each of these pairs will be assessed against one another using the `objFnCompare`, after standardizing each independently. The standardization, which only occurs if the abs(data value < 1), is: mean(abs(derived value - data value))/mean(data value).

If the data value is between -1 and 1, then there is no standardization. If there is more than one data–pattern pair, then they will simply be added together in the objective function. This gives equal weight to each pair. If the user wishes to put different weight on each pattern, a `weights` vector can be provided. This will be used to multiply the standardized values described above. Alternatively, the user may wish to weight them differently, in which case, their relative scales can be adjusted.

There are many options that can be passed to `DEoptim`, (the details of which are in the help), using `optimControl`. The defaults sent from `POM` to `DEoptim` are: steptol = 3 (meaning it will start assessing convergence after 3 iterations (WHICH MAY NOT BE SUFFICIENT FOR YOUR PROBLEM), NP = 10 * length(params) (meaning the population size is 10 x the number of parameters) and itermax = 200 (meaning it won’t go past 200 iterations). These and others may need to be adjusted to obtain good values. NOTE: `DEoptim` does not provide a direct estimate of confidence intervals. Also, convergence may be unreliable, and may occur because `itermax` is reached. Even when convergence is indicated, the estimates are not guaranteed to be global optima. This is different than other optimizers that will normally indicate if convergence was not achieved at termination of the optimization.

Using this function with a parallel cluster currently requires that you pass `optimControl = list(parallelType = 1)`, and possibly package and variable names (and does not yet accept the `cl` argument). See examples. This setting will use all available threads on your computer. Future versions of this will allow passing of a custom cluster object via `cl` argument. `POM` will automatically determine packages to load in the spawned cluster (via `packages`) and it will load all objects in the cluster that are necessary, by sending `names(objects)` to `parVar` in `DEoptim.control`.

Setting `logObjFnVals` to TRUE may help diagnosing some problems. Using the POM derived objective function, essentially all patterns are treated equally. This may not give the correct behaviour for the objective function. Because `POM` weighs the patterns equally, it may be useful to use the log files to examine the behaviour of the pattern–data pairs. The first file, `ObjectiveFnValues.txt`, shows the result of each of the (possibly logged), pattern–data deviations, standardized, and weighted. The second file, "ObjectiveFnValues_RawPatterns.txt", shows the actual value of the pattern (unstandardized, unweighted, unlogged). If `weights` is passed, then these weighted values will be reflected in the 'ObjectiveFnValues.txt' file.

**Value**

A list with at least 2 elements. The first (or first several) will be the returned object from the optimizer. The second (or last if there are more than 2), named `args` is the set of arguments that were passed into the control of the optimizer.

priority 

<table>
<thead>
<tr>
<th>Event priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>priority</td>
</tr>
</tbody>
</table>

**Description**

Preset event priorities: 1 = first (highest); 5 = normal; 10 = last (lowest).

**Usage**

- .first()
- .highest()
- .last()
- .lowest()
- .normal()

**Value**

A numeric.

**Author(s)**

Alex Chubaty
progressInterval

*Get and set simulation progress bar details*

**Description**

The progress bar can be set in two ways in SpaDES. First, by setting values in the .progress list element in the params list element passed to `simInit`. Second, at the `spades` call itself, which can be simpler. See examples.

**Usage**

```r
progressInterval(sim)

## S4 method for signature 'simList'
progressInterval(sim)
progressInterval(sim) <- value

## S4 replacement method for signature 'simList'
progressInterval(sim) <- value

progressType(sim)

## S4 method for signature 'simList'
progressType(sim)
progressType(sim) <- value

## S4 replacement method for signature 'simList'
progressType(sim) <- value
```

**Arguments**

- `sim` A `simList` object from which to extract element(s) or in which to replace element(s).
- `value` The object to be stored at the slot.

**Details**

Progress Bar: Progress type can be one of "text", "graphical", or "shiny". Progress interval can be a numeric. These both can get set by passing a `.progress = list(type = "graphical", interval = 1)` into the `simInit` call. See examples.

**See Also**

Other functions to access elements of a `simList` object: `.addDepends`, `doEvent.checkpoint`, `envir.events.globals`, `inputs`, `modules`, `objs`, `packages`, `params`, `paths`, `times`
Examples

```r
## Not run:
mySim <- simInit(
  times = list(start=0.0, end=100.0),
  params = list(globals = list(stackName = "landscape"),
               progress = list(type = "text", interval = 10),
               checkpoint = list(interval = 10, file = "chkpt.RData"),
               modules = list("randomLandscapes"),
               paths = list(modulePath = system.file("sampleModules", package = "SpaDES.core")))

# progress bar
progressType(mySim) # "text"
progressInterval(mySim) # 10

# parameters
params(mySim) # returns all parameters in all modules
  # including .globals, .progress, .checkpoint
globals(mySim) # returns only global parameters

# checkpoint
checkpointFile(mySim) # returns the name of the checkpoint file
  # In this example, "chkpt.RData"
checkpointInterval(mySim) # 10

## End(Not run)
```

Description

Wrapper to the `raster` function, that creates the raster object in memory, even if it was read in from file.

Usage

```r
rasterToMemory(x, ...)
```

## S4 method for signature 'ANY'
rasterToMemory(x, ...)

Arguments

- `x` An object passed directly to the function `raster` (e.g., character string of a filename).
- `...` Additional arguments to `raster`.
remoteFileSize

Value

A raster object whose values are stored in memory.

Author(s)

Eliot McIntire and Alex Chubaty

See Also

raster.

remoteFileSize    Determine the size of a remotely hosted file

Description

Query a remote web server to determine the size of a remote file.

Usage

remoteFileSize(url)

Arguments

url             The url of the remote file.

Value

A numeric indicating the size of the remote file in bytes.

Author(s)

Eliot McIntire and Alex Chubaty

Examples

          "http://example.com/doesntexist.csv")
try(remoteFileSize(urls)) ## 5429, 3997384, 0
**rndstr**  
*Generate random strings*

**Description**
Generate a vector of random alphanumeric strings each of an arbitrary length.

**Usage**
```r
rndstr(n, len, characterFirst)
## S4 method for signature 'numeric,numeric,logical'
rndstr(n, len, characterFirst)
## S4 method for signature 'numeric,numeric,missing'
rndstr(n, len)
## S4 method for signature 'numeric,missing,logical'
rndstr(n, characterFirst)
## S4 method for signature 'missing,numeric,logical'
rndstr(len, characterFirst)
## S4 method for signature 'numeric,missing,missing'
rndstr(n)
## S4 method for signature 'missing,numeric,missing'
rndstr(len)
## S4 method for signature 'missing,missing,logical'
rndstr(characterFirst)
## S4 method for signature 'missing,missing,missing'
rndstr(n, len, characterFirst)
```

**Arguments**
- `n` Number of strings to generate (default 1). Will attempt to coerce to integer value.
- `len` Length of strings to generate (default 8). Will attempt to coerce to integer value.
- `characterFirst` Logical, if TRUE, then a letter will be the first character of the string (useful if being used for object names).

**Value**
Character vector of random strings.
Author(s)

Alex Chubaty and Eliot McIntire

Examples

set.seed(11)
rndstr()
rndstr(len = 10)
rndstr(characterFirst = FALSE)
rndstr(n = 5, len = 10)
rndstr(n = 5)
rndstr(n = 5, characterFirst = TRUE)
rndstr(len = 10, characterFirst = TRUE)
rndstr(n = 5, len = 10, characterFirst = TRUE)

saveFiles

Save objects using `.saveObjects` in `params` slot of `simInit`

Description

In the `simInit` call, a parameter called `.saveObjects` can be provided in each module. This must be a character string vector of all object names to save. These objects will then be saved whenever a call to `saveFiles` is made.

Usage

`saveFiles(sim)`

Arguments

- `sim` A `simList` simulation object.

Details

The file names will be equal to the object name plus `time(sim)` is appended at the end. The files are saved as `.rds` files, meaning, only one object gets saved per file.

For objects saved using this function, the module developer must create save events that schedule a call to `saveFiles`.

If this function is used outside of a module, it will save all files in the `outputs(sim)` that are scheduled to be saved at the current time in the `simList`.

There are 3 ways to save objects using `SpaDES`.

1. Model-level saving

Using the `outputs` slot in the `simInit` call. See example in `simInit`. This can be convenient because it gives overall control of many modules at a time, and it gets automatically scheduled during the `simInit` call.
2. Module-level saving

Using the `saveFiles` function inside a module. This must be accompanied by a `.saveObjects` list element in the `params` slot in the `simList`. Usually a module developer will create this method for future users of their module.

3. Custom saving

A module developer can save any object at any time inside their module, using standard R functions for saving R objects (e.g., `save` or `saveRDS`). This is the least modular approach, as it will happen whether a module user wants it or not.

Note

It is not possible to schedule separate saving events for each object that is listed in the `.saveObjects`.

Author(s)

Eliot McIntire
Alex Chubaty

Examples

```r
## Not run:

# This will save the "caribou" object at the save interval of 1 unit of time
# in the outputPath location
outputPath <- file.path(tempdir(), "test_save")
times <- list(start = 0, end = 6, "month")
parameters <- list(
  .globals = list(stackName = "landscape"),
  caribouMovement = list(
    .saveObjects = "caribou",
    .saveInitialTime = 1, .saveInterval = 1
  ),
  randomLandscapes = list(.plotInitialTime = NA, nx = 20, ny = 20)
),
modules <- list("randomLandscapes", "caribouMovement")
paths <- list(
  modulePath = system.file("sampleModules", package = "SpaDES.core"),
  outputPath = savePath
)
mySim <- simInit(times = times, params = parameters, modules = modules,
  paths = paths)

# The caribou module has a saveFiles(sim) call, so it will save caribou
spades(mySim)
dir(outputPath)

# remove the files
file.remove(dir(savePath, full.names = TRUE))
```
scheduleConditionalEvent

Schedule a conditional simulation event

Description

Adds a new event to the simulation’s conditional event queue, updating the simulation object by creating or appending to `sim$._conditionalEvents`. This is very experimental. Use with caution.

Usage

```r
scheduleConditionalEvent(sim, condition, moduleName, eventType, 
                         eventPriority = .pkgEnv$.normalVal, minEventTime = start(sim), 
                         maxEventTime = end(sim))
```

Arguments

- **sim**: A `simList` simulation object.
- **condition**: A string, call or expression that will be assessed for `TRUE` after each event in the regular event queue. It can access objects in the `simList` by using functions of `sim`, e.g., `"sim$age > 1"`
- **moduleName**: A character string specifying the module from which to call the event. If missing, it will use `currentModule(sim)`.
- **eventType**: A character string specifying the type of event from within the module.
- **eventPriority**: A numeric specifying the priority of the event. Lower number means higher priority. As a best practice, it is recommended that decimal values are conceptually grouped by their integer values (e.g., 4.0, 4.25, 4.5 are conceptually similar). See `priority`.
- **minEventTime**: A numeric specifying the time before which the event should not occur, even if the condition is met. Defaults to `start(sim)`.
- **maxEventTime**: A numeric specifying the time after which the event should not occur, even if the condition is met. Defaults to `end(sim)`.

Value

Returns the modified `simList` object, i.e., `sim$._conditionalEvents`

This conditional event queue will be assessed at every single event in the normal event queue. If there are no conditional events, then `spades` will proceed as normal. As conditional event conditions are found to be true, then it will trigger a call to `scheduleEvent(...)` with the current time passed to `eventTime` and it will remove the conditional event from the conditional queue. If the user would like the triggered conditional event to occur as the very next event, then a possible strategy would be to set `eventPriority` of the conditional event to very low or even negative to ensure it gets inserted at the top of the event queue.
**scheduleEvent**

**Schedule a simulation event**

**Description**

Adds a new event to the simulation’s event queue, updating the simulation object.

**Usage**

```r
scheduleEvent(sim, eventTime, moduleName, eventType,
    eventPriority = .pkgEnv$.normalVal, .skipChecks = FALSE)
```

**Arguments**

- `sim` A simList simulation object.
- `eventTime` A numeric specifying the time of the next event.
- `moduleName` A character string specifying the module from which to call the event. If missing, it will use `currentModule(sim)`
- `eventType` A character string specifying the type of event from within the module.
scheduleEvent

eventPriority  A numeric specifying the priority of the event. Lower number means higher priority. As a best practice, it is recommended that decimal values are conceptual grouped by their integer values (e.g., 4.0, 4.25, 4.5 are conceptually similar). See priority.

.skipChecks  Logical. If TRUE, then internal checks that arguments match expected types are skipped. Should only be used if speed is critical.

Details

Here, we implement a simulation in a more modular fashion so it's easier to add submodules to the simulation. We use S4 classes and methods, and use 'data.table' instead of 'data.frame' to implement the event queue (because it is much faster).

Value

Returns the modified simList object.

Show an Object

### Usage

```r
# S4 method for signature 'simList'
show(object)
```

### Arguments

- `object`  
- `simList`

### Author(s)

Alex Chubaty

---

**simInit**  

Initialize a new simulation

### Description

Create a new simulation object, the "sim" object. This object is implemented using an environment where all objects and functions are placed. Since environments in R are pass by reference, "putting" objects in the sim object does no actual copy. The `simList` also stores all parameters, and other important simulation information, such as times, paths, modules, and module load order. See more details below.

### Usage

```r
simInit(times, params, modules, objects, paths, inputs, outputs, loadOrder, 
        notOlderThan = NULL)
```

```r
# S4 method for signature
# 'list,list,list,list,list,data.frame,data.frame,character'
simInit(times,
        params, modules, objects, paths, inputs, outputs, loadOrder,
        notOlderThan = NULL)
```

```r
# S4 method for signature 'ANY,ANY,ANY,character,ANY,ANY,ANY,ANY'
simInit(times, params,
        modules, objects, paths, inputs, outputs, loadOrder,
```
\[ \text{notOlderThan} = \text{NULL} \]

```r
## S4 method for signature 'ANY,ANY,character,ANY,ANY,ANY,ANY,ANY'
simInit(times, params, 
    modules, objects, paths, inputs, outputs, loadOrder, 
    notOlderThan = NULL)
```

### Arguments

- **times**
  - A named list of numeric simulation start and end times (e.g., `times = list(start = 0.0, end = 10.0)`).

- **params**
  - A list of lists of the form `list(moduleName=list(param1=value, param2=value))`. See details.

- **modules**
  - A named list of character strings specifying the names of modules to be loaded for the simulation. Note: the module name should correspond to the R source file from which the module is loaded. Example: a module named "caribou" will be sourced from the file `caribouNr`, located at the specified `modulePath(simList)` (see below).

- **objects**
  - (optional) A vector of object names (naming objects that are in the calling environment of the `simInit`, which is often the `.GlobalEnv` unless used programmatically – NOTE: this mechanism will fail if object name is in a package dependency), or a named list of data objects to be passed into the `simList` (more reliable). These objects will be accessible from the `simList` as a normal list, e.g., `mySim$obj`.

- **paths**
  - An optional named list with up to 4 named elements, `modulePath`, `inputPath`, `outputPath`, and `cachePath`. See details. NOTE: Experimental feature now allows for multiple `modulePaths` to be specified in a character vector. The modules will be searched for sequentially in the first `modulePath`, then if it doesn't find it, in the second etc.

- **inputs**
  - A `data.frame`. Can specify from 1 to 6 columns with following column names: `objectName` (character, required), `file` (character), `fun` (character), `package` (character), `interval` (numeric), `loadTime` (numeric). See `inputs` and vignette("iimodules") section about inputs.

- **outputs**
  - A `data.frame`. Can specify from 1 to 5 columns with following column names: `objectName` (character, required), `file` (character), `fun` (character), `package` (character), `saveTime` (numeric). See `outputs` and vignette("iimodules") section about outputs.

- **loadOrder**
  - An optional list of module names specifying the order in which to load the modules. If not specified, the module load order will be determined automatically.

- **notOlderThan**
  - A time, as in from `Sys.time()`. This is passed into the Cache function that wraps `.inputObjects`. If the module uses the `.useCache` parameter and it is set to `TRUE` or `".inputObjects"`, then the `.inputObjects` will be cached. Setting `notOlderThan = Sys.time()` will cause the cached versions of `.inputObjects` to be refreshed, i.e., rerun.
Details

Calling this `simInit` function does the following:

<table>
<thead>
<tr>
<th>What</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>fills simList slots</td>
<td>places the arguments <code>times</code>, <code>params</code>, <code>modules</code>, <code>paths</code> into equivalently named simList slots</td>
</tr>
<tr>
<td>sources all module files</td>
<td>places all function definitions in the simList, specifically, into a sub-environment of the main simList environment</td>
</tr>
<tr>
<td>copies objects</td>
<td>from disk into the simList environment</td>
</tr>
<tr>
<td>loads objects</td>
<td>Objects can be loaded into the simList at any time during a simulation</td>
</tr>
<tr>
<td>schedule object loading/copying</td>
<td>Objects can be saved to disk at any arbitrary time during the simulation. If specified here, this takes time units of modules and how they fit together</td>
</tr>
<tr>
<td>schedule object saving</td>
<td>via the inputs and outputs identified in their metadata. This gives the order of the .inputObjects functions from every module in the module order as determined above</td>
</tr>
<tr>
<td>assesses module dependencies</td>
<td>determines time unit</td>
</tr>
<tr>
<td>runs .inputObjects functions</td>
<td></td>
</tr>
</tbody>
</table>

params can only contain updates to any parameters that are defined in the metadata of modules. Take the example of a module named, Fire, which has a parameter named `.plotInitialTime`. In the metadata of that module, it says TRUE. Here we can override that default with: `list(Fire=list(.plotInitialTime=NA))`, effectively turning off plotting. Since this is a list of lists, one can override the module defaults for multiple parameters from multiple modules all at once, with say: `list(Fire = list(.plotInitialTime = NA, .plotInterval = NA))`.

We implement a discrete event simulation in a more modular fashion so it is easier to add modules to the simulation. We use S4 classes and methods, and fast lists to manage the event queue.

paths specifies the location of the module source files, the data input files, and the saving output files. If no paths are specified the defaults are as follows:

- **cachePath**: `getOption("reproducible.cachePath")`;
- **inputPath**: `getOption("spades.modulePath")`;
- **modulePath**: `getOption("spades.inputPath")`;
- **inputPath**: `getOption("spades.outputPath")`.

Value

A simList simulation object, pre-initialized from values specified in the arguments supplied.

Parsing and Checking Code

The `simInit` function will attempt to find usage of `sim$xxx` or `sim[['xxx']]` on either side of the assignment `"<-"` operator. It will compare these to the module metadata, specifically `inputObjects` for cases where objects or "gotten" from the simList and `outputObjects` for cases where objects are assigned to the simList.

It will also attempt to find potential, common function name conflicts with things like `scale` and `stack` (both in base and raster), and `Plot` (in `quickPlot` and some modules).

This code checking is young and may get false positives and false negatives – i.e., miss things. It also takes computational time, which may be undesirable in operational code. To turn off checking (i.e., if there are too many false positives and negatives), set the option `spades.moduleCodeChecks` to FALSE, e.g., `options(spades.moduleCodeChecks = FALSE)`
Caching

Using caching with SpaDES is vital when building re-usable and reproducible content. Please see the vignette dedicated to this topic.

Note

Since the objects in the simList are passed-by-reference, it is useful to create a copy of the initialized simList object prior to running the simulation (e.g., mySimOut <- spades(Copy(mySim))). This ensures you retain access to the original objects, which would otherwise be overwritten/modified during the simulation.

The user can opt to run a simpler simInit call without inputs, outputs, and times. These can be added later with the accessor methods (See example). These are not required for initializing the simulation via simInit. All of modules, paths, params, and objects are needed for successful initialization.

                 stringsAsFactors = FALSE))
)

# add times by accessor fails all.equal test because "year" was not
# declared during module loading, so month became the default

times(mySim2) <- list(current = 0, start = 0.0, end = 2.0, timeunit = "year")
all.equal(mySim, mySim2) # fails because time units are all different, so
# several parameters that have time units in
# "months" because they were loaded that way
params(mySim)$fireSpread$.plotInitialTime
params(mySim2)$fireSpread$.plotInitialTime
events(mySim) # load event is at time 1 year
events(mySim2) # load event is at time 1 month, reported in years because of
  # update to times above

## End(Not run)

---

**simInitAndSpades**

*Call simInit and spades or experiment together*

**Description**

These functions are convenience wrappers that may allow for more efficient Caching. Passes all
arguments to simInit, then passes the created simList to spades or experiment.

**Usage**

```
simInitAndSpades(times, params, modules, objects, paths, inputs, outputs,
                  loadOrder, notOlderThan, debug, progress, cache, .plotInitialTime,
                  .saveInitialTime, ...)
```

```
simInitAndExperiment(times, params, modules, objects, paths, inputs,
                     outputs, loadOrder, notOlderThan, replicates, dirPrefix, substrLength,
                     saveExperiment, experimentFile, clearSimEnv, cl, ...)
```
Arguments

times  A named list of numeric simulation start and end times (e.g., times = list(start = 0.0, end = 10.0)).

params A list of lists of the form list(moduleName=list(param1=value, param2=value)).
See details.

modules A named list of character strings specifying the names of modules to be loaded for the simulation. Note: the module name should correspond to the R source file from which the module is loaded. Example: a module named "caribou" will be sourced from the file `caribou.R`, located at the specified modulePath(simList) (see below).

objects (optional) A vector of object names (naming objects that are in the calling environment of the simInit, which is often the .GlobalEnv unless used programmatically – NOTE: this mechanism will fail if object name is in a package dependency), or a named list of data objects to be passed into the simList (more reliable). These objects will be accessible from the simList as a normal list, e.g., mySim$obj.

paths An optional named list with up to 4 named elements, modulePath, inputPath, outputPath, and cachePath. See details. NOTE: Experimental feature now allows for multiple modulePaths to be specified in a character vector. The modules will be searched for sequentially in the first modulePath, then if it doesn't find it, in the second etc.

inputs A data.frame. Can specify from 1 to 6 columns with following column names: objectName (character, required), file (character), fun (character), package (character), interval (numeric), loadTime (numeric). See inputs and vignette("ii-modules") section about inputs.

outputs A data.frame. Can specify from 1 to 5 columns with following column names: objectName (character, required), file (character), fun (character), package (character), saveTime (numeric). See outputs and vignette("ii-modules") section about outputs.

loadOrder An optional list of module names specifying the order in which to load the modules. If not specified, the module load order will be determined automatically.

notOlderThan A time, as in from Sys.time(). This is passed into the Cache function that wraps .inputObjects. If the module uses the .useCache parameter and it is set to TRUE or ",.inputObjects", then the .inputObjects will be cached. Setting notOlderThan = Sys.time() will cause the cached versions of .inputObjects to be refreshed, i.e., rerun.

debug Optional logical flag or character vector indicating what to print to console at each event. See details. Default is to use the value ingetOption("spades.debug").

progress Logical (TRUE or FALSE show a graphical progress bar), character ("graphical", "text") or numeric indicating the number of update intervals to show in a graphical progress bar.

cache Logical. If TRUE, then the spades call will be cached. This means that if the call is made again with the same simList, then 'spades' will return the return value from the previous run of that exact same simList. Default FALSE. See Details. See also the vignette on caching for examples.
.plotInitialTime
Numeric. Temporarily override the .plotInitialTime parameter for all modules. See Details.

.saveInitialTime
Numeric. Temporarily override the .plotInitialTime parameter for all modules. See Details.

... Arguments passed to simInit, and spades or experiment

replicates
The number of replicates to run of the same simList. See details and examples.

dirPrefix
String vector. This will be concatenated as a prefix on the directory names. See details and examples.

substrLength
Numeric. While making outputPath for each spades call, this is the number of characters kept from each factor level. See details and examples.

saveExperiment
Logical. Should params, modules, inputs, sim, and resulting experimental design be saved to a file. If TRUE are saved to a single list called experiment. Default TRUE.

experimentFile
String. Filename if saveExperiment is TRUE; saved to outputPath(sim) in .RData format. See Details.

clearSimEnv
Logical. If TRUE, then the envir(sim) of each simList in the return list is emptied. This is to reduce RAM load of large return object. Default FALSE.

c1
A cluster object. Optional. This would generally be created using parallel::makeCluster or equivalent. This is an alternative way, instead of beginCluster(), to use parallelism for this function, allowing for more control over cluster use.

Details

simInitAndExperiment cannot pass modules or params to experiment because these are also in simInit. If the experiment is being used to vary these arguments, it must be done separately (i.e., simInit then experiment).

Value

Same as spades (a simList) or experiment (list of simList objects)

See Also

simInit, spades experiment

---

**simList-class**

*The simList class*

**Description**

Contains the minimum components of a SpaDES simulation. Various slot accessor methods (i.e., get and set functions) are provided (see 'Accessor Methods' below).
Details

Based on code from chapter 7.8.3 of Matloff (2011): "Discrete event simulation". Here, we implement a discrete event simulation in a more modular fashion so it’s easier to add simulation components (i.e., "simulation modules"). We use S4 classes and methods, and use `data.table` instead of `data.frame` to implement the event queue (because it is much more efficient).

Slots

- **modules** List of character names specifying which modules to load.
- **params** Named list of potentially other lists specifying simulation parameters.
- **events** The list of scheduled events (i.e., event queue), as a `data.table`. See 'Event Lists' for more information.
- **current** The current event, as a `data.table`. See 'Event Lists' for more information.
- **completed** The list of completed events, as a list. See 'Event Lists' for more information. It is kept as a list of individual events for speed. The completed method converts it to a sorted `data.table`.
- **depends** A `.simDeps` list of `.moduleDeps` objects containing module object dependency information.
- **simtimes** List of numerical values describing the simulation start and end times; as well as the current simulation time.
- **inputs** a `data.frame` or `data.table` of files and metadata
- **outputs** a `data.frame` or `data.table` of files and metadata
- **paths** Named list of `modulePath`, `inputPath`, and `outputPath` paths. Partial matching is performed.
- **.xData** Environment referencing the objects used in the simulation. Several "shortcuts" to accessing objects referenced by this environment are provided, and can be used on the `simlist` object directly instead of specifying the `.xData` slot: $, $, `ls`, `ls.str`, `objs`. See examples.
- **.envir** Deprecated. Please do not use any more.

Accessor Methods

Several slot (and sub-slot) accessor methods are provided for use, and categorized into separate help pages:

- **simList-accessors-envir** Simulation environment.
- **simList-accessors-events** Scheduled and completed events.
- **simList-accessors-inout** Passing data in to / out of simulations.
- **simList-accessors-modules** Modules loaded and used; module dependencies.
- **simList-accessors-objects** Accessing objects used in the simulation.
- **simList-accessors:params** Global and module-specific parameters.
- **simList-accessors-paths** File paths for modules, inputs, and outputs.
- **simList-accessors-times** Simulation times.
Event Lists

The main event list is a sorted data.table (keyed) on eventTime, and eventPriority. The completed event list is an ordered list in the exact order that the events were executed. Each event is represented by a data_table row consisting of:

- **eventTime**: The time the event is to occur.
- **moduleName**: The module from which the event is taken.
- **eventType**: A character string for the programmer-defined event type.
- **eventPriority**: The priority given to the event.

**Note**

The simList class extends the environment, by adding several slots that provide information about the metadata for a discrete event simulation. The environment slot, if accessed directly is .xData and this is where input and output objects from modules are placed. The simList class is similar, but it extends the list class. All other slots are the same. Thus, simList is identical to simList_, except that the former uses an environment for objects and the latter uses a list. The class simList_ is only used internally.

**spades**

*Run a spatial discrete event simulation*

**Description**

Here, we implement a simulation in a more modular fashion so it's easier to add submodules to the simulation. We use S4 classes and methods, and use ‘data.table’ instead of ‘data.frame’ to implement the event queue (because it is much faster).

**Usage**

```
spades(sim, debug =getOption("spades.debug"), progress = NA, cache, 
.plotInitialTime = NULL, .saveInitialTime = NULL, 
notOlderThan = NULL, ...)
```

```
# S4 method for signature 'simList,ANY,ANY,missing'
spades(sim, 
  debug = getOption("spades.debug"), progress = NA, cache,
```

spades

.splotInitialTime = NULL, .saveInitialTime = NULL,
notOlderThan = NULL, ...) 

## S4 method for signature 'ANY,ANY,ANY,logical'
spades(sim,
  debug = getOption("spades.debug"), progress = NA, cache,
  .plotInitialTime = NULL, .saveInitialTime = NULL,
  notOlderThan = NULL, ...)

### Arguments

- **sim**: A simList simulation object, generally produced by `simInit`.
- **debug**: Optional logical flag or character vector indicating what to print to console at each event. See details. Default is to use the value in `getOption("spades.debug")`.
- **progress**: Logical (TRUE or FALSE) show a graphical progress bar, character ("graphical", "text") or numeric indicating the number of update intervals to show in a graphical progress bar.
- **cache**: Logical. If TRUE, then the spades call will be cached. This means that if the call is made again with the same simList, then 'spades" will return the return value from the previous run of that exact same simList. Default FALSE. See Details. See also the vignette on caching for examples.
- **.plotInitialTime**: Numeric. Temporarily override the .plotInitialTime parameter for all modules. See Details.
- **.saveInitialTime**: Numeric. Temporarily override the .plotInitialTime parameter for all modules. See Details.
- **notOlderThan**: Date or time. Passed to `reproducible::cache` to update the cache. Default is NULL, meaning don’t update the cache. If `Sys.time()` is provided, then it will force a recache, i.e., remove old value and replace with new value. Ignored if cache is FALSE.
- **...**: Any. Can be used to make a unique cache identity, such as "replicate = 1". This will be included in the Cache call, so will be unique and thus spades will not use a cached copy as long as anything passed in ... is unique, i.e., not cached previously.

### Details

The is the workhorse function in the SpaDES package. It runs simulations by implementing the rules outlined in the simList.

This function gives simple access to two sets of module parameters: .plotInitialTime and with .plotInitialTime. The primary use of these arguments is to temporarily turn off plotting and saving. "Temporary" means that the simList is not changed, so it can be used again with the simList values reinstated. To turn off plotting and saving, use .plotInitialTime = NA or .saveInitialTime = NA. NOTE: if a module did not use .plotInitialTime or .saveInitialTime, then these arguments will not do anything.
If cache is TRUE, this allows for a seamless way to "save" results of a simulation. The user does not have to intentionally do any saving manually. Instead, upon a call to spades in which the simList is identical, the function will simply return the result that would have come if it had been rerun. Use this with caution, as it will return exactly the result from a previous run, even if there is stochasticity internally. Caching is only based on the input simList. See also experiment for the same mechanism, but it can be used with replication. See also the vignette on caching for examples.

**Value**

Invisibly returns the modified simList object.

**debug**

dep can be a logical, character vector or a numeric scalar (currently 1 or 2). If debug is specified and is not FALSE, 2 things could happen: 1) there can be messages sent to console, such as events as they pass by, and 2) if options("spades.browserOnError" = TRUE) (experimental still) if there is an error, it will attempt to open a browser in the event where the error occurred. You can edit, and then press c to continue or Q to quit, plus all other normal interactive browser tools. c will trigger a reparse and events will continue as scheduled, starting with the one just edited. There may be some unexpected consequences if the simList objects had already been changed before the error occurred.

If not specified in the function call, the package option spades.debug is used. The following options for debug are available:

- **TRUE**
  - function name (as character string)
  - moduleName (as character string)
  - eventName (as character string)
  - `c(<moduleName>, <eventName>)`

Any other R expression expressed as a character string

A numeric scalar, currently 1 or 2 (maybe others)

information that users may find useful

- the event immediately following will be printed as it runs (equivalent to `currentHsimI`
- If a function, then it will be run on the simList, e.g., "time" will run `timeHsimI`
- All calls to that module will be entered interactively
- All calls that have that event name (in any module) will be entered interactively
- Only the event in that specified module will be entered into.

Will be evaluated with access to the simList as 'sim'. If this is more than one, this will print out alternative forms of event information that users may find useful.

**Note**

The debug option is primarily intended to facilitate building simulation models by the user. Will print additional outputs informing the user of updates to the values of various simList slot components. See [https://github.com/PredictiveEcology/SpaDES/wiki/Debugging](https://github.com/PredictiveEcology/SpaDES/wiki/Debugging) for details.

Examples

```r
## Not run:
mySim <- simInit(
  times = list(start = 0.0, end = 2.0, timeunit = "year"),
  params = list(
    .globals = list(stackName = "landscape", burnStats = "nPixelsBurned")
  ),
  modules = list("randomLandscapes", "fireSpread", "caribouMovement"),
  paths = list(modulePath = system.file("sampleModules", package = "SpaDES.core"))
)
spades(mySim)

# set default debug printing for the current session
# setOption(spades.debug = TRUE)

# Different debug options (overrides the package option 'spades.debug')
spades(mySim, debug = TRUE) # Fastest
spades(mySim, debug = "simList")
spades(mySim, debug = "print(table(sim$landscape$Fires[]))")

# Can turn off plotting, and inspect the output simList instead
out <- spades(mySim, .plotInitialTime = NA) # much faster
completed(out) # shows completed events

# use cache -- simInit should generally be rerun each time a spades call is made
# to guarantee that it is identical. Here, run spades call twice, first
# time to establish cache, second time to return cached result
for (i in 1:2) {
  mySim <- simInit(
    times = list(start = 0.0, end = 2.0, timeunit = "year"),
    params = list(
      .globals = list(stackName = "landscape", burnStats = "nPixelsBurned")
    ),
    modules = list("randomLandscapes", "fireSpread", "caribouMovement"),
    paths = list(modulePath = system.file("sampleModules", package = "SpaDES.core"))
  )
  print(system.time(out <- spades(mySim, cache = TRUE)))
}

## End(Not run)

suppliedElsewhere

Description

These S4 classes are defined within SpaDES. "dot" classes are not exported and are therefore intended for internal use only.

Simulation classes

- **simList**: The 'simList' class
- **.moduleDeps**: Descriptor object for specifying SpaDES module dependencies
- **.simDeps**: Defines all simulation dependencies for all modules within a SpaDES simulation

Author(s)

Eliot McIntire and Alex Chubaty

See Also

- **simInit**

suppliedElsewhere

Assess whether an object has or will be supplied from elsewhere

Description

When loading objects into a simList, especially during the simInit call, and inside the .inputObjects functions of modules, it is often useful to know if an object in question will or has been by the user via the inputs or objects arguments, or by another module’s .inputObjects while preparing its expected inputs (via expectsInputs in metadata), or if it will be supplied by another module during its "init" event. In all these cases, it may not be necessary for a given module to load any default value for its expectsInputs. This function can be used as a check to determine whether the module needs to proceed in getting and assigning its default value.

Usage

```r
suppliedElsewhere(object, sim, where = c("sim", "user", "initEvent"), returnWhere = FALSE)
```

Arguments

- **object**: Character vector
- **sim**: A simList in which to evaluated whether the object is supplied elsewhere
- **where**: Character vector with one to three of "sim", "user", or "initEvent". Default is all three. Partial matching is used. See details.
returnWhere Logical, default FALSE, whether the vector of length 3 logical should be returned, or a logical of length one

Details

where indicates which of three places to search, either "sim" i.e., the simList, which would be equivalent to is.null(sim$objName), or "user" which would be supplied by the user in the simInit function call via outputs or inputs (equivalent to (!('defaultColor' %in% sim$.$userSuppliedObjNames))), or "initEvent", which would test whether a module that gets loaded before the present one will create it as part of its outputs (i.e., as indicated by createsOutputs in that module’s metadata). There is a caveat to this test, however; if that other event also has the object as an expectsInput, then it would fail this test, as it also needs it as an input. This final one ("initEvent") does not explicitly test that the object will be created in the "init" event, only that it is in the outputs of that module, and that it is a module that is loaded prior to this one.

Examples

mySim <- simInit()
suppliedElsewhere("test", mySim) # FALSE

# supplied in the simList
mySim$test <- 1
suppliedElsewhere("test", mySim) # TRUE
test <- 1

# supplied from user at simInit time -- note, this object would eventually get into the simList
# but the user supplied values come after the module's .inputObjects, so
# a basic is.null(my$test) would return TRUE even though the user supplied test
mySim <- simInit(objects = list("test" = test))
suppliedElsewhere("test", mySim) # TRUE

## Not run:
# Example with prepInputs
# Put chunks like this in your .inputObjects
if (!suppliedElsewhere("test", mySim))
  sim$test <- Cache(prepInputs, "raster.tif", "downloadedArchive.zip",
    destinationPath = dataPath(sim), studyArea = sim$studyArea,
    rasterToMatch = sim$otherRasterTemplate, overwrite = TRUE)

## End(Not run)

Description

Functions for the simtimes slot of a simList object and its elements. To maintain modularity, the behaviour of these functions depends on where they are used. In other words, different modules can have their own timeunit. SpaDES converts these to seconds when running a simulation, but shows the user time in the units of the model as shown with timeunit(sim)
Usage

times(x, ...)

## S4 method for signature 'simList'
times(x)
times(x) <- value

## S4 replacement method for signature 'simList'
times(x) <- value

## S3 method for class 'simList'
time(x, unit, ...)
time(x) <- value

## S4 replacement method for signature 'simList'
time(x) <- value

d(x, ...)

## S3 method for class 'simList'
d(x, unit, ...)
ed(x) <- value

## S4 replacement method for signature 'simList'
ed(x) <- value

start(x, ...)

## S3 method for class 'simList'
start(x, unit = NULL, ...)
start(x) <- value

## S4 replacement method for signature 'simList'
start(x) <- value

timeunit(x)

## S4 method for signature 'simList'
timeunit(x)
timeunit(x) <- value

## S4 replacement method for signature 'simList'
timeunit(x) <- value
timeunits(x)

## S4 method for signature 'simList'
timeunits(x)

elapsedTime(x, ...)

## S3 method for class 'simList'
elapsedTime(x, byEvent = TRUE, ...)

**Arguments**

- `x` A `simList`
- `...` Additional parameters.
- `value` A time, given as a numeric, optionally with a unit attribute, but this will be deduced from the model time units or module time units (if used within a module).
- `unit` Character. One of the time units used in Spades.
- `byEvent` Logical. If `TRUE`, the elapsed time will be by module and event; `FALSE` will report only by module. Default is `TRUE`.

**Details**

timeunit will extract the current units of the time used in a simulation (i.e., within a spades call). If it is set within a `simInit`, e.g., `times=list(start=0, end=52, timeunit = "week"),` it will set the units for that simulation. By default, a `simInit` call will use the smallest unit contained within the metadata for the modules being used. If there are parent modules, then the parent module `timeunit` will be used even if one of its children is a smaller `timeunit`. If all modules, including parents, are set to `NA`, `timeunit` defaults to seconds. If parents are set to `NA`, then the set of modules defined by that parent module will be given the smallest units of the children.

Currently, available units are "second", "hours", "day", "week", "month", and "year" can be used in the metadata of a module.

The user can also define a new unit. The unit name can be anything, but the function definition must be of the form `dunitName`, e.g., `dyear` or `dfortnight`. The unit name is the part without the `d` and the function name definition includes the `d`. This new function, e.g., `dfortnight <- function(x) lubridate::duration(x)` can be placed anywhere in the search path or in a module.

timeunits will extract the current units of the time of all modules used in a simulation. This is different from `timeunit` because it is not necessarily associated with a spades call.

In many cases, the "simpler" use of each of these functions may be slower computationally. For instance, it is much faster to use `time(sim, "year")` than `time(sim)`. So as a module developer, it is advantageous to write out the longer one, minimizing the looking up that R must do.

**Value**

Returns or sets the value of the slot from the `simList` object.
updateList

Note
These have default behaviour that is based on the calling frame timeunit. When used inside a
module, then the time is in the units of the module. If used in an interactive mode, then the time
will be in the units of the simulation.

Additional methods are provided to access the current, start, and end times of the simulation:

- **time**: Current simulation time.
- **start**: Simulation start time.
- **end**: Simulation end time.
- **timeunit**: Simulation timeunit.
- **timeunits**: Module timeunits.
- **times**: List of all simulation times (current, start, end, timeunit).

Author(s)
Alex Chubaty and Eliot McIntire

See Also
- **SpaDES.core-package**, specifically the section 1.2.5 on Simulation times.
- Other functions to access elements of a simList object: .addDepends, doEvent.checkpoint,
envir, events, globals, inputs, modules, objs, packages, params, paths, progressInterval

updateList  
*Update elements of a named list with elements of a second named list*

Description
Merge two named list based on their named entries. Where any element matches in both lists, the
value from the second list is used in the updated list. Subelements are not examined and are simply
replaced. If one list is empty, then it returns the other one, unchanged.

Usage
```r
updateList(x, y)
```

```r
## S4 method for signature 'list,list'
updateList(x, y)
```

```r
## S4 method for signature '\NULL\',list'
updateList(x, y)
```

```r
## S4 method for signature 'list,\NULL\'
updateList(x, y)
```

```r
## S4 method for signature '\NULL\,\NULL\'
updateList(x, y)
```
Arguments

x  a named list
y  a named list

Value

A named list, with elements sorted by name. The values of matching elements in list y replace the values in list x.

Author(s)

Alex Chubaty

Examples

L1 <- list(a = "hst", b = NA_character_, c = 43)
L2 <- list(a = "gst", c = 42, d = list(letters))
updateList(L1, L2)

updateList(L1, NULL)
updateList(NULL, L2)
updateList(NULL, NULL) # should return empty list

zipModule  Create a zip archive of a module subdirectory

Description

The most common use of this would be from a "modules" directory, rather than inside a given module.

Usage

zipModule(name, path, version, data = FALSE, ...)

## S4 method for signature 'character,character,character'
zipModule(name, path, version,
    data = FALSE, ...)

## S4 method for signature 'character,missing,character'
zipModule(name, path, version,
    data = FALSE, ...)

## S4 method for signature 'character,missing,missing'
zipModule(name, path, version,
    data = FALSE, ...)
### S4 method for signature 'character,character,missing'

```r
zipModule(name, path, version, 
  data = FALSE, ...)
```

#### Arguments

- **name**  
  Character string giving the module name.
- **path**  
  A file path to a directory containing the module subdirectory.
- **version**  
  The module version.
- **data**  
  Logical. If TRUE, then the data subdirectory will be included in the zip. Default is FALSE.
- **...**  
  Additional arguments to `zip` e.g., add "-q" using flags="-q -r9X" (the default flags are "-r9X").
